THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

VOLUME XVI.

FROM NOVEMBER 13, 1885, TO MAY 7, 1886.

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at "THE ELECTRICIAN" Offices, 1, Salisbury-court, Fleet-street, E.C.

1886.

v. 16

51286

INDEX TO VOL. XVI.

A

Abel, Sir F., Presidential Address to Society of Arts, 54.
Abney, Capt., and Festing, Col., Chromatic Photometry 395
Accident to Electric Light Workmen, 453.
Adams, A. J. S., The Sun, 226.
Adams, W. G. Lighthouse Illuminants, 57, 76, 97, 115, 135.
Africa, Contract for New Cable to, 358, 370.
Amalgamation, Expansion produced by, 442.
Ammeter and Voltmeter, New, 475, 493.
Andrews J. D. F., Rule for Finding Current Direction, &c., 97.
Anglo-American Brush Corporation (Leading Article), 310.
Arc Lamp, The Brockie-Pell, 127.
Arc Lamp, The Lever, 169.
Arc Lamps, Retrospective Notes, 26.
Arc Lamps, Small, 389, 393, 497.
Armatures, Ring, their Proportions, by G. C. Fricker, 449, 472.
Atlantic Cables, 291, 494.
Ayrton and Perry, Profs., Papers by :—
- Amalgamation, 442.
- Economy in Conductors, 354, 366, 378, 432.
- Expansion of Mercury, 442.
- Some Thermo-dynamical Relations, 235.
- Voltmeters, 153, 166.

B

Baily and Grundy's Cut-out, 457.
Baines, A. E., Cables; the Copper Resistance Test, 188.
Baines, A. E., Cables and Earth Currents, 111.
Bassano and Co., Liquidation of, 460.
Batteries, Primary :—
- E.M.F. of Dry Ones, 169.
- Gaiffe's Standard Cell, 89.
- Ross's for Lighting, 52.
- Tin Cells, by E. T. Herroun, 38.

Batteries, Secondary :—
- Elwell-Parker Charge Indicator for, 335.
- Electrical Power Storage Company's Cells, 393.

Beetz, W. V., Dry Batteries, 169.
Bernstein A., Lighting by Glow Lamps, 415, 481.
Bedwell, S., Changes produced in Strained Iron Wires by Magnetisation, 500.
Blasting by Electricity, 329.
Block System in Europe and America, 513.
Bonelli's Experiments on Electrical Saponification, 97.
Boys's Equation Solving Machine, 98.
British Association, Report of Committee on Standards of White Light, 78.
British Electric Light Company, Winding-up of, 298.
Brockie-Pell Arc Lamp, 127.
Brooks's Underground and Overhead System, 14.
Business Notices, 20, 120, 240, 260, 280, 300, 380.

C

Cable :—
- to Africa, Debate on Contract for, 358, 370.
- Early, Insulation Resistance of, 13.
- Localising Fault in, by H. Kingsford, 114, 232.
- New Persian Gulf, 18, 235.
- Steamer "Mirror," Launch of, 139.
- Tariffs, Reduction in, 457.

Cables :—
- Atlantic, 291.
- The Copper Resistance Test, by A. E. Baines, 188
- and Earth Currents, by A. E. Baines, 111.
- in War, 93.

Cantor Lectures (*see* FORBES).
Carhart, H. S., E.M.F.'s Represented by an Hyperbola, 311.
Carhart, H. S., Minimum E.M.F. in Transmitting Power, 113.
Carleton's Firedamp Indicator, 491.
Carpenter, Lant, The Electric Telegraph, 56.
Chambers, J. M., Maxwell's Theory of Light, 255.
Champain, Sir J. U. B., Report on Persian Gulf Cable, 235.
Christmas Box, A, 73.
Chromatic Photometry, by Capt. Abney and Col. Festing, 395.
City and Guilds Institute, 474.
Clayden, A. W., Heat Capacity of a Thermometer, 235.
Clerc's Commutator, 69.
Colonial and Indian Exhibition, Machinery Shed at, 514.
Commutator for Incandescent Circuits, 69.

COMPANIES' MEETINGS, REPORTS, &c. :—
- Anglo-American Brush, 260, 277.
- Anglo-American Telegraph, 178, 240, 275.
- Blackpool Electric Tramway, 99.
- Brazilian Submarine, 217, 524.
- Cuba Submarine, 240, 258.
- Direct Spanish Telegraph, 380, 396.
- Direct United States Cable, 200, 238.
- Eastern Extension Telegraph, 19, 444, 460.
- Eastern Telegraph, 199, 217, 237.
- Electrical Power Storage, 397.
- German Union Telegraph, 395.
- India Rubber, Gutta Percha, &c., 280, 299, 359.
- Indo-European Telegraph, 444, 483.
- Lancashire Maxim-Weston, 240.
- Maxim-Weston, 219, 259, 274, 318.
- Mediterranean Extension Telegraph, 139.
- Montevidean and Brazilian Telegraph, 443.
- National Company for the Distribution, &c., 360, 379.
- Oriental Telephone, 463, 483.
- Phosphor Bronze, 280.
- Pilsen-Joel, &c., 40.
- Railway and Electric Appliances Company, 524.
- Reuter's, 484, 503.
- Submarine, 279, 299.
- Submarine Cables Trust, 524.
- Swan Electric Light, 120, 320, 380, 393.
- Telegraph Construction, 339.
- Telephone Company of Austria, 279.
- Telephone Company of Egypt, 360, 379.
- Western and Brazilian Telegraph, 200, 218.
- Western Counties Telephone, 423.
- West India and Panama Telegraph, 20, 38.

Conductors, Economy in, by Profs. Ayrton and Perry, 354, 366, 378, 432.
Cooper *v.* Slatter, 19.
Copper, Apparatus for Estimating, by A. H. Low, 109.

CORRESPONDENCE :—
- Alldred, Wm., Dynamo as Generator, 269.
- Animal Electricity, 291.
- Arc Lamps, Candle-power of, 72.
- Armature Resistance, 414.
- Armatures, Ring, 472
- Ayrton, Prof. W. E., Law of the Dynamo, 31.
- Batteries, Primary, Wirt's Modification of Daniell's, 214.
- Batteries, Primary, for Electric Lighting, 457, 472.
- Batteries, Secondary, 247, 351, 369, 414.
- Bernstein, A., Light obtained from Incandescent Carbon, 36.
- Bichromate for Batteries, 153.
- Blavier Cable Tests, Formulæ for Maintaining Constancy of Currents, 267.
- Bosanquet, R. H. M., Dynamos, 71.
- Bosanquet, R. H. M., Law of the Electro-Magnet, 247.
- Brand, C. T. B., Generators and Motors, 213.
- Cable-Laying, 332.
- Cable Testing, Kennelly's Formulæ for, 267.
- Carbon, Incandescent, Light obtained from, 36.
- Carbon Rod, Query as to Resistance of, 11.
- Correction, A., Fricker on Ring Armatures, 472.
- Correction, A., Prof. Thompson's Book, 331, 332, 349, 353, 369, 391, 413, 435, 456.
- Crompton, R. E., Electric *v.* Oil Lamps, 435.
- Crompton, R. E., Electric Lighting Act Amendment Bill, 437.
- Crompton and Co., High-speed Engines, 36, 91.
- Current Distribution, Economical, 193.
- Current, Hypnotic Effect of, 495.
- Current Induction, Phenomenon of, 35, 51, 71, 111, 131.
- Current, Self-induction of, 349, 455, 471, 495.
- Cut-outs, Hedges's, 37, 497, 510.
- Daniell Cell, Wirt's Modification, 214.
- Deprez and Power Transmission, 175.
- Discovery, Another, 372.
- Distribution of Current, Economical, 193.
- Distribution by Transformers, 391, 436, 472.
- Drake, B., Secondary Batteries, 247.
- Dynamos :—
  - Armature Resistance, 414.
  - Efficiency, Tests of 371.
  - as Generator and Motor, 208, 213, 228, 249, 269.
  - by Glow Lamps, 472.
  - the Law of, 31, 247.
  - by Primary Batteries, 457, 472.
  - Ratio of Magnetism to Magnetising Force, 71.
  - Prof. S. P. Thompson's Book on, 331, 349, 353, 369, 391, 413, 435, 456.
- Edison's Telephonic Receiver, a Query, 311.
- Electric Bells, 131.
- Electric Boy, The, 131, 153, 175, 193, 214, 251, 292, 311, 333, 353.
- Electric Haulage, 71, 92.
- Electric *v.* Oil Lamps for Lighthouses, 437.
- Electric Lighting Act Amendment Bill, 437.

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.

THE ELECTRICIAN:

A WEEKLY JOURNAL OF

THEORETICAL AND APPLIED ELECTRICITY AND CHEMICAL PHYSICS.

No. 1.—Vol. XVI. FRIDAY, NOVEMBER 13, 1885. Price 4d.

NOTES.

The Electric Light for Warships.—H.M.S. "Boadicea" is to be fitted at Portsmouth with the electric light.

The Antwerp Exhibition.—The exhibitors at this Exhibition propose to entertain the Executive at a banquet on the 29th instant.

Epstein Accumulators. — The current number of *La Lumière Electrique* contains an account of the construction of these accumulators.

Brazilian Submarine Telegraph Company.—The traffic receipts of this company for the week ended 6th inst. amounted to £3,047.

The West Coast of America Telegraph Company.—The gross earnings of this company for the month ending October 31st were £3,475.

The Telephone in Germany.—In Berlin and its suburbs the number of subscribers to the telephone already exceeds 7,000, and is continually on the increase.

An Opportunity.—At the last ordinary meeting of the Mansfield Woodhouse Local Board Mr. Marlow gave notice of motion that it was desirable to let the public lighting by tender.

Personal.—Mr. H. Goodwin, having recovered from his illness, contracted in India, has been appointed manager and electrician of the Oriental Telephone Company's system at Mauritius.

Earthquakes.—Two severe shocks of earthquake, passing from west to east, were felt on the Lis Island, in the parish of Sorunda, Sweden, on the 9th ultimo between the hours of 9 and 10 a.m.

"The Encyclopædia Britannica."—The last volume of this encyclopædia has, in the section devoted to physiology, a quantity of interesting matter upon the electrical condition of the human body.

The Telegraph in Japan.—According to recent statistics, Japan possessed in 1881 4,000 miles of telegraphs, with a total of 10,000 miles of wire. A special modification of the Morse code, having forty-seven signals, is used.

The Royal Society. — Considerations of health have induced Prof. Huxley to place in the hands of the council of the Royal Society his resignation of the office of president, and the resignation has been accepted. His successor is Prof. Stokes.

The Telegraph in Italy.—The province of Sienne, in Italy, possesses 11 telegraph offices belonging to the Government, and 13 offices under the control of the various railways. The number of messages transmitted amounts to about 900,000 per annum.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ended 6th November, were £2,366, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

The French in Annam and Tonquin.—It is said that all telegraphic communication between Annam and Saïgon is suppressed by the military authorities. General Prudhomme has forbidden the sending even of private telegrams unless they have his personal *visa*.

Fireman's Electric Lamp.—A portable incandescent lamp, fed by a bichromate battery, and intended for the use of firemen, has been introduced by Messrs. Merryweather. Except as regards its outer casing the lamp does not differ from those with which we are already familiar.

The Electric Light and the Lord Mayor's Show.—The four Pilsen lamps used on the occasion of the late civic show to illuminate the historical erection in Aldersgate were supplied by Messrs. Paterson and Cooper, and run from a Phœnix dynamo at their works in Little Britain.

City and Guilds of London Institute.—Alderman Sir R. N. Fowler, Bart., M.P., has consented to present the Institute's scholarships, prizes, and certificates at a meeting to be held on Wednesday evening, 9th December, at the Salters' Hall, St. Swithin's-lane, E.C. The Right Hon. the Lord Mayor will preside.

The Pilsen-Joel and General Electric Light Company.—Notice is given that the fourth ordinary general meeting of the shareholders of this company will be held at the Cannon-street Hotel, Cannon-street, in the City of London, on Thursday, the 19th November, at two o'clock in the afternoon.

The Lighting of the Budapest Exhibition.—The lighting of this Exhibition has, with the exception of a few Egger lamps, been entirely carried out by Ganz and Co., of Budapest. The installation includes about 116 arc and 1,200 incandescent lamps, and about ten slow-speed dynamos, driven, principally, by a 70 horse-power steam engine.

The Alternative Route to the Cape.—We are in a position to state that, practically speaking, all arrangements have been made for laying and maintaining a line of submarine cables along the West African coast, giving us not only telegraphic communication with our West African Colonies, but the much-agitated-for alternative route to the Cape.

The Telegraph in the Far East.—It is reported that the telegraph line is constructed to the Kala Abdullah, and

Digitized by Google

is working. During Sir Donald Stewart's late stay there, sufficient material was stored at Quetta to carry the line to Herat if necessary. This department is well directed and efficient, keeping abreast of possible requirements in India.

Colonial and Indian Exhibition.—H.R.H. the Prince of Wales has appointed Sir Frederick Abel, Sir Francis Bolton, and Mr. Preece a Committee of Advice to deal with the important question of the electric illumination of the grounds and buildings next year. Mr. Cundall has also been appointed by H.R.H. as engineer in charge of the machinery and plant.

Accidents in Mines Commission.—Meetings of this commission were held on Tuesday and Wednesday at its offices, 2, Victoria-street, Westminster. There were present the chairman, Mr. Warrington W. Smyth, Sir Frederick Abel, C.B.; Mr. Thomas Burt, M.P.; Professor Clifton, Mr. W. Thomas Lewis, Professor Tyndall, and the secretary, Mr. Arthur J. Williams.

Fond of Experiments!—In the Westminster Police-court recently, William Marriott, sixteen, a chemist's assistant, was charged on remand with stealing an electric "motor," value 30s., the property of the Electric Apparatus Company, at the Inventions Exhibition.—The prisoner's mother said he was passionately fond of experiments in electricity.—Mr. Sheil, in the result, took the mother's bail for prisoner to come up if called upon and allowed him to go, with a strong caution as to the future.

The Telephone in Canada.—A new telephone system is about to be inaugurated in Ottawa, in which many great improvements are introduced. The combined result of these changes is that speech with good articulation can be modulated and distinctly heard at any distance within twenty and even thirty feet from the ear, thus avoiding all danger or annoyance, and at the same time liberating the hand from the fatigue of holding a telephone. It is intended to establish a manufactory in Ottawa.

New Room at the British Museum.—At the British Museum a new and commodious reading room has been opened for the use of persons who wish to consult the files of the daily and weekly papers. It is in the new wing at the east end of the Museum, facing Montagu-street, is fitted with larger and broader tables than those in the circular reading room, and is well lighted and ventilated. The furnishing and decoration of the room are nearly completed, and it will be eventually lighted with the electric light.

Electrolysis of Salts.—In a paper recently read before the Academie des Sciences, M. Renard stated that in solutions sufficiently dilute the amount of metal precipitated is proportional to the concentration of the liquid. The proportions of metal deposited are in the same relation as their atomic weights. According to the law of Faraday the quantity of metal precipitated being proportional to the intensity of the current, the conductivity of solutions containing equivalent atomic weights of metal is the same; as M. Bouty has sufficiently demonstrated.

The South of England Telephone Company.—We are pleased to see that Mr. Grahame, who displayed a considerable degree of energy in getting together a *clientèle* for the Northampton exchange of this company, has, in little more than two months, succeeded in doubling the original list of subscribers. We understand that it is proposed to connect Northampton with the smaller towns of Wellingborough, Kettering, and Rushden; a scheme which, if carried into effect, will greatly increase the importance of Northampton as a telephonic centre.

Telephone Litigation in America.—The New York correspondent of the *Standard* says that the Department of the Interior is now considering an application to annul Bell's telephone patent. Prof. Gray has made an affidavit in which he asserts that he filed a caveat and deposited a working model the same day that Bell filed his application for a multiplex telegraph; that Gray's caveat was treacherously taken to Bell's counsel, who revised Bell's papers so as to include the telephone, thus wholly changing the character of Bell's claim, and substantially embodying Gray's invention.

Direct Communication with Spain Restored.—The Direct Spanish Telegraph Company notify the repair of their direct cable route to Spain *viâ* Bilbao. This has been a most remarkable piece of work on the part of the new ship "Electra," and reflects very great credit indeed upon Captain Pattison and every one concerned. The cable was picked up in 2,200 fathoms, and put through in less than three working days. We doubt whether as smart a performance is on record, although the ss. "Chiltern," if we remember rightly, approached it a few years ago in the Bay of Biscay. The depth in that case was, we think, 2,000 fathoms.

The National Telephone Company.—From this company's October list of subscribers we notice that in the Aberdeen district there are now 510 instruments in operation, the number of exchange connections, including switch lines, being 455. In addition to these there are 29 private lines, making a total of nearly 265 miles of wire. The longest line is that to the Culter Paper Mills, which measures 8 miles 447 yards, and the longest private line is from Ellon to Newburgh, a distance of 5 miles 870 yards. In other districts the company have much more extensive lines in operation, notably, between Glasgow and Edinburgh, and Glasgow and Greenock.

The Life of Incandescent Lamps.—Some of the Edison and Swan incandescent lamps, placed two and a half years ago on the Great Eastern Railway Company's steamer, "Norwich," running between Harwich and Antwerp, are still living. Though only guaranteed for 1,000 hours, they have lasted close upon 7,500 hours, for their light is on about fifty-six hours a week, and the steamer has only been fourteen days off the station. Although most have been replaced, so as to avoid the chance of their suddenly going out, two of the original lamps are retained in the saloon by way of curiosity, and their light is only a trifle less brilliant than that of the others.

The Manchester Art Gallery.—At a recent meeting of the Manchester City Council Mr. Alderman Hopkinson said the Council would be pleased to learn that the receipts for admission to the present autumn exhibition at the City Art Gallery were considerably in excess of those of any former year, whilst the sales were even more satisfactory. The preparations for lighting the gallery by means of electricity were very nearly completed, and he hoped to be able in a few days to invite the members of the Council to go and see the effect of it. Meanwhile, the gallery could not be lighted in the evening, on account of the objection which owners of pictures raised to gas.

Applications of the Telephone.—A recent interesting exhibition of apparatus in Paris, by Dr. Boudet, included a modification of the telephone adapting the instrument to a variety of medical uses. In one form the pulsations of blood vessels and all sorts of internal operations were very strikingly made audible, the observer being able to hear at will the movements in any part of the body. Another telephonic appliance detected the presence of stones in the bladder, and even made

Digitized by Google

known their character when present. Dr. Boudet also employs the telephone as a measuring instrument for accurately estimating the nervous and muscular excitement in the different phases of a disease.

Manufacture of Bichromate of Potash.—An improved method of manufacturing bichromate of potash has been devised by Mr. Rœmer, of Elberfeld. A concentrated solution of sodium bichromate is dissolved in boiling water and potassium chloride added. This mixture is then maintained at the boiling point until a mutual decomposition takes place, potassium bichromate and sodium chloride being formed. The mother liquor is concentrated, so that sodium chloride is salted out, which is removed and washed with hot water, and instead of bichromate the neutral chromate of sodium may be employed, in which case the solution is first sufficiently acidulated with hydrochloric acid to be transformed into bichromate; when the latter is treated as before mentioned.

A Story about Morse.—Florence, the actor, tells this story:—"I can remember," he said, "years and years ago, going to a dinner, given to Morse. He was an elegant old gentleman, but awfully long-winded. I had a friend with me. We listened to Morse, while he predicted great things for electricity. I remember he predicted, too, that some day men would be able to talk over the wires for distances of fifty miles, and that every ship that left harbour for an ocean voyage would be connected with the land by wires. When he got that far my friend said, 'What rot!' and we went out. I have often remembered how foolish his talk sounded to me. Yet it has been all realised, except as regards ships at sea. I believe even that will come about some day."

An Important Modification.—Mr. C. M. Gavill has presented to the Physical Society, in the name of Mr. Guerin, a cell whose liquids have been rendered immovable, and which is as a consequence portable. This result has been obtained by substituting for water a solution of agar-agar, an alga that comes from the far East. The liquid upon cooling becomes a solid and elastic jelly. The proportion of agar-agar may vary from one to five per cent., and depends upon the substances that are to be mixed with liquid. The model that Mr. Guerin has studied is the agglomerate Leclanché. Its electromotive force is slightly less (0·03 to 0·04 volt) than that of the ordinary styles of the pile. The resistance of one of these elements of medium dimensions is about 0·9 ohm. The same process may be applied to any other primary cell.

The Humming of the Wires.—Mr. M'Bride, of Indiana, has come to the conclusion that the humming of telegraph and telephone wires is not caused by the wind. He has devoted a great deal of time and attention to the matter, and has found that the sound is more appreciable on a clear, calm evening than at any other time. He is also convinced that the effect is not due to electricity, for he could detect no signs of that agent when the humming was in full force, while at times when the wire was evidently carrying current there was no sound. Mr. M'Bride considers the question a subject of investigation which may lead to important discoveries. We consider that Mr. M'Bride is mistaken in both his deductions and his conclusion. The humming is set up by vibration, which may be due to a number of simple causes, and transmitted from one point to another, even at a considerable distance.

A Visit to the Consolidated.—We learn that Mr. Todd, the Postmaster-General of South Australia, and Mr. Cracknell, Superintendent of Telegraphs for New South Wales, last week visited the factory of the Consolidated Telephone Construction and Maintenance Company, and expressed themselves highly pleased with what they saw there. The visitors were accompanied round the works by the chairman of the company and Mr. George A. Mason, the manager. The machinery lately introduced from America attracted considerable attention, as did the process of making magnets. The switchboards of the consolidated pattern got their full meed of praise, and the latest improvement, the new magnet bell with tooth-wheel gear and patent cut-out, met with approval. The Consolidated transmitter was also examined. The company claim that this instrument is the best transmitter of the human voice at present known.

Absolutely the Latest Motor.—The following curious circular has recently been issued; our readers will be able to form their own opinions of it. We are not interested in steam engines generally, but we have friends who think much of them. For their sakes, therefore, we are rather glad than otherwise that the inventor of the wonderful machine below mentioned is impecunious. Were it not so, it is dreadful to think what a revolution in science might be brought about by this gentleman's motor:—"A friend has arrived with a very valuable invention. It is a machine which works and has the power of a steam engine, without fuel or element; it can be used for tramways, mining purposes, factories, railways, and ships. The machine requires only one man for stopping or setting it in motion. One of the largest will only require two men for attention. *The machine is not subject to breakage*, therefore a great saving *on coals* and labour can be effected. To build such a machine will not cost more than a steam engine of its same power. The inventor wants to sell the invention, or to treat with gentlemen with the view of getting same patented in the whole world. *His capital is limited.*" "His capital is limited;" pathetic, but reassuring. The italics are our own.

Electro-Technics in Germany.—The following synopsis of courses in electro-technics at the various high schools in Germany is calculated to impress one with a colossal respect for minds which with so little tuition can grasp the technical and the abstruse. Berlin:—Electro-technics, four lessons; telegraphy, four lessons; practice in the electrical laboratory, six lessons; electric lighting and its various methods (special course for engineers), two lessons. Brunswick:—Electro-technics (theoretic and practical), four lessons; practice in laboratory, two lessons; other subjects, seven lessons. Darmstadt:—Electro-technics, two lessons; electrical machines, two lessons; electric lighting, two lessons; telegraphy and telephony, two lessons; submarine telegraphy, one lesson; practical exercises, six lessons; theory of potential, two lessons; application of electricity to railway work, two lessons; electro-dynamics, including induction, two lessons; practical telegraphy, one lesson, &c. At the end of the scholastic year the students are required to pass the examinations and receive certificates of competency. The subjects remaining about the same, Dresden offers a total course of seven lessons; Hanover, thirteen; Carlsruhe, five; Munich, eighteen; and Stuttgart, six. Cheerful prospect!

Society of Arts.—The hundred and thirty-second session of the Society of Arts will commence on Wednesday, the 18th inst., when the opening address will be delivered by Sir Frederick Abel, C.B., D.C.L., LL.D., F.R.S., chairman of the council. The following are amongst the papers announced: Prof. Silvanus P. Thompson, "Apparatus for the Automatic Extinction of Fires." Prof. Francis Elgar, LL.D., F.R.S.E., M.Inst.C.E., "The Load Line of Ships." F. Edward Hulme, F.L.S., F.S.A., "Technical Art Teaching." Dr. C. Meymott Tidy, "The Treatment of Sewage." C. V.

Digitized by Google

Boys, "Calculating Machines." George Clulow, "The History and Manufacture of Playing Cards." W. H. Preece, F.R.S., "Domestic Electric Lighting." Prof. R. Meldola, F.C.S., "The Scientific Development of the Coal Tar Industry." Six courses of Cantor Lectures have been arranged—"The Microscope," by John Mayall, jun.; "Friction," by Prof. H. S. Hele Shaw; "Science Teaching," by Prof. F. Guthrie, F.R.S.; "Petroleum and its Products," by Boverton Redwood, F.C.S.; "The Arts of Tapestry Making and Embroidery," by Alan S. Cole; "Animal Mechanics," by B. W. Richardson, M.A., M.D., F.R.S. The subject of the Juvenile Lectures this year will be on "Waves," and the lecturer, Prof. Silvanus P. Thompson, D.Sc. Dates and further particulars will be announced in the Society of Arts *Journal*.

The Electric Light and the Hastings Town Council.—At the last usual monthly meeting of this Council, the annexed recommendation in regard to the electric light was read:—"The committee recommend that the existing contract with the Electric Light Company, for the lighting of the front, from the Queen's Hotel to Warrior-square, by means of fifteen 2,000 nominal candle-power arc lamps, for the sum of £450 per annum, which expires on the 26th inst., be renewed for another year."—Mr. Alderman Davis had great pleasure in moving the adoption of the report. He was disappointed at not being able to move a report embodying a more extended use of the light. It was very well known that the Electric Light Company had been in considerable difficulties during the last year or two, and had not yet felt themselves able to go in for a more extensive application of the light to the town. He hoped in another year to find that the company were in a position to extend the operation of the light, not necessarily along the parades east and west, but in the inland parts of the borough. They really could not now do without their beautiful light on the front.—Mr. Duke seconded with a great deal of pleasure. The expense was a great deal, it was true, but it was patent to everyone that the light was a most essential and admirable arrangement. It was a great pity that at present the committee were unable to extend the area of the lighting; but whilst they could have the light along the front he thought they should endeavour to continue the expense of it. They must keep pace with other towns in this matter. The report was then adopted, without opposition.

American Items.—A novel application of the electric light is to be seen in Philadelphia, where miniature incandescent lamps of 1 candle-power are used, among other things, for illuminating clock dials at night. One of the things for which Bellows Falls (Mass.) people are largely indebted to the extensive paper manufacturers of the locality is the electric light, which is furnished to the village merchants and others for a small sum. The Fall Mountain Company furnishes the power for no less than 800 electric lights, 400 or 500 of which are used in the company's different mills, and the balance by the village storekeepers and others, who are charged but 1 cent. an hour for the use of each light, which is of 16 candle-power. These lights give such general satisfaction that it seems quite likely that within a few months the plant will be so extended as to furnish many of the village dwellings with a light which it is claimed by those now using it is cheaper even than kerosene. Salina, Kan., has granted the franchise to the Salina Electric Light Company to furnish the city with Edison incandescent light, the works to be in operation by June 1, 1886.—The chimney at the waterworks pumping station at Fall River, R. I., which was struck by lightning several weeks ago, has resisted all efforts to pull it down. October 23, a company of the 1st Regiment stationed a 12-pound gun 200 feet distant and with one solid shot and thirteen unloaded shells knocked down the 40ft. of chimney forming the dangerous portion.—The Jarvis Engineering Company, of Boston, have received the contract to furnish the steam plant for the new Edison Lighting Company, of New Bedford, Mass. They will put in two Armington and Sims engines, two 6 by 16 steel tubular boilers set with the Jarvis furnace, national feed-water heater, Davidson steam pump, Korting injector, &c.

The Electric Light and Stage Effect.—At many theatres, both in London and the provinces, the electric light has been successfully used as an accessory to stage effect. It is not long since we described the very interesting and ingenious installation of arc lamps at Her Majesty's, and we have now to offer our congratulations to Mr. Edgar Bruce, of the Prince's, upon the manner in which he has availed himself of the facilities offered by the incandescent light. Thanks to this gentle illuminant, the theatre over which Mr. Bruce so ably presides is one of the pleasantest in London. Its auditorium is cool, excellently lit, and entirely free from the oppressive odour which results from the combustion of gas. Not only is the installation carried to every part of the building, but great care, attention, and taste have evidently been bestowed upon its arrangement. On the stalls level are the refreshment kiosk and smoking fernery, in which latter the incandescent lamps, half hidden amongst foliage or peeping out from curious little recesses, are most artistically grouped. In the kiosk there are but 12 lamps, in pairs; and in the fernery six only, but on the occasion of our visit they were working up to their full power and gave ample light. Theatrical criticism being somewhat out of our province, we must refrain from a commentary upon the merits of the "Great Pink Pearl" other than to say that it is very, very funny. In the last act, however, a fine effect is introduced by the instantaneous illumination of the interior of the Russian Embassy in Paris by incandescent lamps. An ordinary switch placed near the doorway, and actuated by an attendant in obedience to a simple request for "lights," transforms the stage from almost total darkness to a sudden blaze of light, and produces a powerful impression upon the audience. The whole of the lamps are run from accumulators. The installation, as many of our readers will remember, was put down by Messrs. Strode and Co., who are also to be credited with the last-mentioned arrangement.

An Important Experiment.—Within the area of the torpedo field situated opposite the sea fronts of Forts Monckton and Gilkicker, near Portsmouth, an important experiment in submarine mining has recently been carried out. At each corner of a quadrilateral was sunk a heavy mine, consisting of 500lb. of guncotton, enclosed in wrought-iron cylinders, all four being in separate electrical connection with a battery in Fort Gilkicker. Both within and without the lines, and at various known distances from the charged mines, were submerged a great number of cases of various construction and shape loaded down with dummy guncotton as target mines, and the object of the experiment was to ascertain the effect upon the different structures of exploding heavily charged submarine mines in their neighbourhood. The targets included naval counter-mines, fixed mines, and electro-contact mines, service and experimental. The various mines were all fixed buoyantly, and were destitute of blowing-up charges, as the purpose in view was not to discover whether the explosion of the heavy mines would detonate those in their midst, but to learn the comparative effects of the concussion on the containing vessels and gear, the force of the explosives at different ranges being measured by crusher gauges. Great interest was

Digitized by Google

manifested in the experiment, because of the fact that such heavy charges of guncotton, amounting in the aggregate to 2,000lb., and having an energy equal to about 8,000lb. of gunpowder, had not previously been simultaneously discharged at Portsmouth. The charges were simultaneously exploded from Gilkicker on a half-ebb tide. As a spectacle the effect was somewhat disappointing. The spouts of water were almost connected and were extremely jagged in outline, but they did not rise to the height expected, the stream of mud which overflowed the interior lining of the jets showing that the mines were scarcely buoyant at the time of the explosion. The detonation was not unpleasant on shore, but the radial extension of the disturbance must have been effective, as fish were stunned at considerable distances out to sea. The results of the experiment cannot yet be known.

A New Telephone Exchange.—A meeting of subscribers and others was recently held at the offices of the newly established branch of the West of England and South Wales Telephone Company, situated in Abbey-road, Torquay. The chair was taken by Mr. H. F. Lewis, general manager of the company. The chairman said he hoped to give the town such a telephone service as they would be sure to appreciate. As to the progress of telephony, England was far behind other countries, and especially New York. In one city in America there was a telephone to every twenty of the inhabitants. In London there were about 4,000 subscribers; Manchester, Liverpool, 1,200; Glasgow, 900, at £20 each; in Dundee there were 700, at £15; Bradford, 450, at £15; and Dublin, 710, at £12. At Brighton there were 120, at £12; Plymouth, 50, at rates of £12 for a year, and £11 for three or five years, and £10 for five or seven years; and Portsmouth 30, at £10 for seven years; and at Torquay there were nine already connected, and eight orders on hand, and considering the short time the company had been at work, there was fair progress. It was an entirely new thing in Torquay, and he hoped it would grow. Any exchange having under a hundred subscribers was not of very great service to the subscribers, and of very little profit to the company, and it was to the interests of the public to see in what way the number of subscribers could be increased, for the greater the number the more valuable it would be to them. The company had to pay a royalty of ten per cent. to the Post Office on the gross income, and also royalties to the United Telephone Company for the use of their master patents, viz., Edison's patent (Blake form), and the Bell receiver, so that it would be seen that out of every £10 received they had to pay between £2 and £3 royalties. The instruments in use at this exchange were similar in all respects to those in use elsewhere, and there were about 20,000 in use altogether throughout the United Kingdom. They consisted of Edison's patent transmitters and Bell's receivers, and were excessively sensitive. Owing to this sensitiveness faults occasionally occurred. At Bristol there was an average of 2,000 calls per day, which meant 4,000 communications; of this number there were only an average of four faults per day; in some cases the fault rested with new subscribers, who had not become used to the instrument. The subject had been mentioned of connecting towns together; that he thought might, and no doubt would, come later on. If a sufficient number of subscribers could be obtained the company would be glad to do so. Exeter and Plymouth might be joined up to Torquay. In reply to a question as to what distance a message could be sent by telephone, the chairman said the telephone wire from London to Brighton was fifty-two miles, and from London to Dover, during an experiment, allowing for the special resistance by working through telegraph instruments at stations which had to be overcome, the equivalent was about 280 miles. In the Midlands 156 miles had been spoken through; in America much longer distances than this have been spoken through. The company could not work at lower rates than those proposed. In New York the charge was £30 per annum, and in Paris £25; the former was, he believed, about to be raised to £40, and the latter to £30.

Institution of Civil Engineers of Ireland.—In the course of his address, delivered on the 4th inst., the president of this institution made the following reference to electrical matters:—"Electricity, which has done so much, and with which we have expected to do so much more in many various ways, has not as yet produced a storage battery which is at the same time economical and occupies but a small space. We have not as yet arrived at the time when any one can, with reasonable economy, light his house with incandescent lamps at a price which will compare favourably with ordinary illuminants; and unless the ordinary householder is capable of understanding and attending to an engine and dynamo he must yet wait before he can gain the undoubted advantage of the electric light at a reasonable cost. With large spaces and certain classes of buildings, the case is very different; and when the arc light can, either with or without a certain proportion of incandescent lighting, be used to give large amounts of light, it is found to be economical as compared with its older rival, gas. I would, however, point out that the direction in which even greater economy could be obtained seems to be in the production of cheaper but still reliable carbons. Unless carbons are of the best possible kind they flicker and give off a large quantity of dust, which gets into and clogs up the mechanism of the lamps. In order to illustrate how important is the question of the cost of carbons I may mention that in a large installation with which I am familiar the carbons cost 40 cent. of the whole expense of working; wages amount to 30 per cent.; coal to only 14 per cent.; the remaining 16 per cent. being made up of all the smaller items of repairs, oils, tallow, waste, leather belts, &c. Those who have had anything to do with the erection of electric lighting plant cannot help being struck with the number of German workmen who are employed in connection with this work, and is it no doubt due to their possessing a greater knowledge of electricity and chemistry which our own workmen have not the same facilities for obtaining; and this fact is but one of many which may be brought forward to illustrate the necessity of the establishment of technical and scientific schools in our large towns. How little has been done in England and Ireland, and how much in Germany, to foster scientific and also technical education was shown in the admirable address of Dr. Lyon Playfair to the British Association. The difficulties which exist with regard to small installations of electric light for household purposes are almost the same as those which prevent its use for the lighting of railway trains. Several experimental trains have been lit, and some of them are still running on various lines in England, with incandescent lamps. In one system an engine and dynamo is fixed on the locomotive, but the light goes out if the locomotive is detached, unless there is a storage battery in the van. In another the dynamo is driven from the axle of the van. In a third storage batteries are entirely depended on; but nothing that I am aware of has as yet been produced in a handy, and at the same time an economical, form which will enable any carriage to be detached from a train and carry its lights with it for a number of hours. What is required is something of the simplest possible character, easily attended to and not demanding of lampmen more intelligence than is now required to turn a gas tap."

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 410, Vol. XV.)

The Magnetic Field due to Impressed E.M.F.

The three sections before the last were principally devoted to the consideration of the electric field set up by impressed electric force, also as modified by previously existing electrification. There is also simultaneously a magnetic field, if there be electric current. This will depend on how the impressed forces are distribut d, which question we need not return to further than to say that should they be wholly in nonconducting regions there can be no steady current, but merely a transient one producing elastic displacement; and that if there be impressed force in a conducting region, which is the first condition for there to be a steady current, it must not be polar in its distribution therein, and with its lines perpendicular to the boundary, or there can be no current again. [The term polar force is borrowed from magnetism to signify any force whose distribution is such that its integral round any closed curve is zero. This is the most useful property by which to identify a polar force. The lines of force start from certain places and terminate at others; these places are the poles, in an extended sense; any pole, positive or negative, may be conceived to send out a definite amount of "force," uniformly in all directions, *i.e.*, according to the inverse square law. The mathematical expression is curl $F=0$, if F be polar; the boundary representation of curl F being the tangential component of F turned through a right angle on the surface. That the lines of F must be perpendicular to a series of surfaces does not sufficiently identify a given force with a polar force, as this is not inconsistent with the integral force in a circuit being a finite quantity, and so giving rise to the corresponding flux.] Thus to have current in a conductor the impressed force must have a finite value in at least one closed path entirely within the conductor. The current thus depends upon the "curl" of the impressed force. This is of great importance in the theory of the Volta force or other boundary forces. The curl of any force is always arranged in closed lines, *e.g.*, the closed line at the common meeting place of zinc and copper (in contact) and a medium surrounding them.

Supposing now the arrangement is such that there is current, the determination of the state of the magnetic field from it is, in comparison with the determination of the state of the electric field anywhere, a comparatively simple matter, the former being a reduced and greatly simplified form of the latter, with changed meanings of the quantities concerned. The flux is the magnetic induction. That has no divergence, to begin with; one simplification as compared with electric displacement. Next, there is no magnetic current, as it ceases when the state becomes steady. And, finally, the ratio of the flux to the force (magnetic), or the permeability, is everywhere finite, so that there is no division of space into permeable and impermeable regions. In brief, the full statement of the conditions is contained in

$$B=\mu H; \quad \text{div.}B=0; \quad \text{curl.}(H-h)=4\pi C; \quad . \quad . \quad (98)$$

the first being the linear connection between the flux and the force, the second expressing the continuity of the flux, and the third the relation between the magnetic force H and the current C, in which h is the impressed force of intrinsic magnetisation $I=\mu h/4\pi$. As, by the linearity of the equations, the field due to C and to h is simply the sum of their separate fields, we may put $h=0$ at once, and therefore deal entirely with induced magnetisation (*quasi*-elastic).

If we integrate the third equation (98) on this understanding, we see that H may be any vector whose curl is $4\pi C$, and is therefore indeterminate as regards a polar force, F. We have then $H=h_1+F$, wherein, on account of the presence of F, we may choose h_1 to have no divergence. It is then definitely given by

$$h_1 = \text{curl of vector potential of C} = \text{curl.}\ \Sigma C/r,$$

if r be the distance from an element of C to the place where h_1 is reckoned.

As thus defined, h_1 is what is usually called the magnetic force of the current. It *is* the magnetic force of the current if there be no variation of permeability anywhere; otherwise it is what the magnetic force would be if there were no such variation. The absolute value of the permeability, provided it be the same everywhere, is a matter of indifference, so far as h_1 is concerned. The polar force F therefore represents the change made in the magnetic force by variations of permeability, due, of course, principally to the presence of iron.

For limited purposes, h_1 may be regarded as the impressed magnetic force due to a distribution of intrinsic magnetisation $I_1=\mu h_1/4\pi$. That is, if we abolish the electic current and substitute I_1, the magnetic force and the induction would be unchanged. But whilst h of real intrinsic magnetisation may be arbitrary, and is usually in very limited portions of matter, the lines of h_1, as we have chosen it, are closed, and extend over all space in general, though by particular arrangements of current they may be shut out from certain spaces.

Let T be the total magnetic energy due to C. The two most noteworthy forms for T are

$$T=\tfrac{1}{2}\Sigma HB/4\pi=\tfrac{1}{2}\Sigma AC \quad . \quad . \quad . \quad . \quad (99)_1$$

the first summation being of the scalar product of the magnetic force and induction ($\div 8\pi$), and probably representing the real distribution of the magnetic energy; the second of half the scalar product of the current and the electric impulse A, which is excessively unlikely to be anything near the real distribution. In $(99)_1$ A may be any vector whose curl is B; but to give it the most physical significance, it is best to take it to be the electric impulse arising from inertia, or the time-integral of the electric force of induction on sudden removal of the impressed force e keeping up C. It is a scientific concept which does not express any physical state or condition. The electric impulse A at a given place does not depend upon the magnetic state there, but upon its condition everywhere; as on removal of e, disturbances are propagated to the place, these determine the electric force of induction whose time integral is A.

Other forms are useful in showing the influence of variable permeability.

Thus
$$\left.\begin{aligned} T &= \tfrac{1}{2}\Sigma h_1 B/4\pi \text{ (because } \Sigma FB=0), \\ &= \tfrac{1}{2}\Sigma h_1 J_1 - \tfrac{1}{2}\Sigma F\mu F/4\pi = \tfrac{1}{2}\Sigma h_1 J_1 - \tfrac{1}{2}\Sigma\Omega\rho \end{aligned}\right\} . \quad (99)_2$$

Here h_1 and J_1 are definitely known, by the preceding. The new quantities Ω and ρ are the magnetic potential and the volume density of magnetic matter; the polar force being the slope of Ω, or $F = -\nabla\Omega$, whilst ρ is given by

$$\rho = \text{conv. } J_1 = -h_1\nabla\mu, \text{ (when } \mu \text{ is scalar).}$$

Thus ρ exists only at places where the permeability varies, therefore mainly at the bounding surfaces of different kinds of matter, or, disregarding perfectly abrupt changes, in thin layers at the bounding surfaces.

If $\nabla\mu$ be perpendicular to h_1, we have $\rho=0$. Hence, starting with μ constant, when h_1 is the real magnetic force, if we select a complete tube of force, or any region bounded wholly by lines of force, and alter its permeability to any other value (constant throughout the region), the magnetic force will be unaltered, whilst the induction will be altered within the the region in the same ratio as the permeability. If now we choose to ignore the changed permeability, we may ascribe the altered induction to an additional electric current, on the surface of the region, perpendicular to the magnetic force and of the proper strength to produce the increased induction. In $(99)_1$, A will be altered by a quantity depending upon this false current. By adding more and more tubes of force to the region, we finally include all space, or alter the permeability everywhere in the same proportion. Then, as might be expected, the false current to account for the increased induction on ignoring the altered permeability occupies the same situation as the real, in fact increasing its strength in the same ratio as the permeability was increased.

There is another form for T which is very curious, related to the electric energy due to the same impressed electric force e. Let U be the total electric energy, then $U=\tfrac{1}{2}\Sigma ED$, if E be the electric force and D the elastic displacement. Now this last is

Digitized by Google

the time-integral of $\dot{D}$ the transient displacement current during the charge. Let $\dot{D}_1$ be the simultaneous transient conductive current, so that their sum is the transient current of induction during the charge, a *closed* system of current which finally ceases, and which, when added to the final current C, makes up the actual current Γ at any moment during the charge. Thus,

$$\Gamma = C + \dot{D} + \dot{D}_1.$$

The time-integral of $\dot{D}_1$ is D_1, the complement of D; the two together being closed. Then, to match $U = \frac{1}{2}\Sigma ED$, we shall have

$$T = -\tfrac{1}{2}\Sigma ED_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (99)_3$$

This we may verify by a former equation. Assuming it to be true, we have

$$\left.\begin{aligned} U - T &= \tfrac{1}{2}\Sigma E\,(D + D_1) = \tfrac{1}{2}\Sigma e\,(D + D_1) \\ \text{or,} \quad 2(U - T) &= \Sigma E\int(\Gamma - C)\,dt = \Sigma e\int(\Gamma - C)\,dt, \end{aligned}\right\} \quad (99)_4$$

by definition of D and D_1, which expresses that the work done by e during the transient state is $2\,(U - T)$ more than if the current started instantly everywhere in its final distribution. This proof of $(99)_3$ therefore rests upon equation (64). But it is easily proved directly, by using the electric impulse A. Thus, by $(99)_1$,

$$T = \tfrac{1}{2}\Sigma AC = \tfrac{1}{2}\Sigma AkE, \text{ if } k = \text{conductivity},$$

$$= \tfrac{1}{2}\Sigma E\int k\dot{A}\,dt.$$

Now, let E_1 be the electric force in the transient state, *i.e.*

$$E^1 = e + f - \dot{A}, \text{ where } f \text{ is polar.}$$

Then $\qquad k\dot{A} = k\,(e + f) - (\Gamma - \dot{D}),$

therefore, $\qquad T = \tfrac{1}{2}\Sigma E\int\{k(e + f) - (C + \dot{D}_1)\}\,dt,$

by definition of D_1; and, since $\Sigma keE = \Sigma eC = \Sigma EC$, and $\Sigma fC = 0$, we are reduced to $(99)_3$ as required.

The equation $(99)_4$ may be transformed to

$$U - T = \tfrac{1}{2}\Sigma Zg \quad . \quad . \quad . \quad . \quad . \quad (99)_5$$

if we have

$$-\,\text{curl.}\,Z = 4\pi(D + D_1), \text{ and } -\,\text{curl.}\,e = 4\pi g.$$

Here g is the false magnetic current corresponding to the impressed force e, going round the lines of e, roughly speaking. And Z may be taken to be the magnetic impulse at a point, the analogue of A, as we may thus verify. By the just given equation of Z, differentiating to the time, we get

$$-\,\text{curl.}\dot{Z} = 4\pi(\dot{D} + \dot{D}_1) = 4\pi(\Gamma - C) = \text{curl}(H_1 - H)$$

if H_1 be the magnetic force at any moment during the transiont period, H being its final value. Therefore

$$-\dot{Z} = H_1 - H + F_1$$

where F_1 is polar, showing that $-\dot{Z}$ may be taken as the magnetic force of induction. Or thus: remove e suddenly, the time integral of the magnetic force in the variable state following at any point will be Z. The definition of Z may be extended so that its time variation shall be the actual magnetic force; but it is simplest, and harmonises best with the electric impulse, to make it refer to the variable state only.

Take e to exist only across a single thin slice of a wire, the most elementary case. Then g will be round the boundary. $D + D_1$ is then the integral current through g during the charge (not counting the final current, if any); or, reversed, it is the integral current through g when e is removed. If this current be oscillatory, it may amount to nothing in the total. If so, the potential and kinetic energies were equal. The value of Z at the place of g is also zero, of course, by $(99)_5$, the magnetic force there reversing with the current. (The place of g is where energy leaves the seat of e when it is working.)

Another pair of allied expressions for the parts of U and T *outside* the conductors.

$$T = \tfrac{1}{2}\int dt\Sigma\text{conv.VE}_1\text{H}/4\pi\,; \quad U = \tfrac{1}{2}\int dt\Sigma\text{conv.VEH}_1/4\pi. \quad (99)_6$$

Here E_1 and H_1 are the values of the electric and magnetic forces at time t after e was started, and E, H, their final values; the time integral to include the transient period, and the Σ being summation through the whole space outside the conductors.

By means of the convergence theorem we may at once transform these expressions to surface integrals over the boundaries of the conductors. Thus, let N be the unit normal out from conductor to non-conductor, and

$$\text{VE}_1\text{N} = 4\pi g_1\,; \quad \text{VNH}_1 = 4\pi\gamma_1\,; \quad \text{VEN} = 4\pi g\,; \quad \text{VNH} = 4\pi\gamma\,;$$

γ and γ_1 being therefore boundary (false) electric, and g, g_1 boundary (false) magnetic currents. Then

$$\left.\begin{aligned} T &= -\tfrac{1}{2}\Sigma H\int g_1 dt = -\tfrac{1}{2}\Sigma\gamma\int E_1 dt = \tfrac{1}{2}\Sigma A\gamma \\ U &= -\tfrac{1}{2}\Sigma E\int\gamma_1 dt = -\tfrac{1}{2}\Sigma g\int H_1 dt = \tfrac{1}{2}\Sigma Zg \end{aligned}\right\} \quad . \quad . \quad (99)_7$$

wherein of course the Σ's are mere surface integrals, since there only are the quantities g and γ. In the last forms, which we had occasion to employ in the last section, A and Z are, as there and in the former part of the present section, the electric and magnetic impulses. Notice, however, that the g in $(99)_7$ is not the same as the g in $(99)_5$, and there defined; the present g extending over all the boundary in general, although, should $T = 0$ (no final current), we see by $(99)_5$ and $(99)_7$ that they are then identical, situated round e, which must reach the boundary.

Here we may notice a peculiarity of interest in connection with the difference of treatment of vectors according as they are closed or polar. Suppose we have two conducting bodies in air, and charge them oppositely by an impressed force in a connecting wire. The electric energy set up is $U = \frac{1}{2}\Sigma Zg$, g being round e only. But now suppose we disconnect the wire from the bodies and take it, with e, away to a distance. We have altered the field very slightly, so that Z has nearly the same value anywhere as before, and U also. But g has gone altogether. How then does $\frac{1}{2}\Sigma Zg$ apply, the force being normal to the conductors?

Notice that, as stated in the last section, this formula only applies when it is possible to close the displacement outside the region in which U exists, so as not to pass through it and alter the field. Thus the formula applies to all the space between the two oppositely charged conductors provided we leave out a little piece joining them, along which to let the displacement return. This little piece may be reduced to a mere line, thus infinitesimally altering the field. The formula then reduces to a line integral, which will be found to become

$$\tfrac{1}{2} \text{ charge} \times \text{difference of potentials,}$$

the common electrostatic formula.

On the other hand, if we join the conductors by a wire through which they will discharge (unless balanced by impressed force in it), the formula acquires reality at once; g at first moment being at place of contact (round the spark) and thereafter over the conducting surface generally. During the discharge there will be a real magnetic current G in space, and the value of U at any moment will be $\frac{1}{2}\Sigma Z(G + g)$. (See last section, p. 409).

(*To be continued.*)

ON THE DESIGN AND CONSTRUCTION OF DYNAMOS.

BY GISBERT KAPP.

(*Continued from page 252, Vol. XV.*)

The equation $R \leqq 10^{-6}\dfrac{TNt\,n}{r_0 + r}$ is very instructive, as it shows which terms tend to increase, and which tend to reduce, the magnetic resistance R. It was pointed out in the preceding article that, on the critical point, when the speed of the dynamo has been reduced to a certain value, at which there is danger that the machine may lose its magnetism altogether, exciting power and electromotive force just balance each other without a margin on either side. This condition of things corresponds to a point on the characteristic curve fairly near

Digitized by Google

the origin; in fact, it is that point where the curve becomes real. It is customary to represent the characteristic of a series-wound dynamo as a continuous curve from the origin to the point of highest E.M.F. and current possible in that particular dynamo. This is not a correct representation, because we are not able to maintain the current and E.M.F. steadily at certain small values between the origin and the critical condition; if we attempt to do this, the machine will either lose its current altogether or it will increase up to the critical value. If the field-magnets be of cast iron, the critical point will naturally lie nearer to the origin, because of the residual magnetism in the field, which facilitates the starting of the current. With wrought-iron field-magnets the critical point will be reached later; but, on the other hand, the characteristic has a more decided upward slope, rendering the machine more suitable for compounding. From the above expression it will be seen that the critical magnetic resistance R may be the greater the more wire is coiled on armature (Nt) and magnets (T) and the higher the speed (n), and that it must be the smaller the greater the electrical resistance of the machine or the outer circuit. In a given dynamo R is fixed by the constructive features of the machine, and the only variables in the expression are n and r. The former we call with Marcel Deprez the *critical speed*, and the latter might be termed the *critical external resistance*. It will be understood that either of these values only becomes critical if the other is arbitrarily fixed. Suppose the external resistance to be fixed, and we wish to know the speed at which the machine will begin to excite itself and give a current. The above equation for R gives

$$n = 10^6 \frac{R(r_0 + r)}{T\,Nt}.$$

If, on the other hand, the speed be fixed, and we require to know the greatest resistance which can be put into the external circuit, we find

$$r = 10^{-6} \frac{T\,Nt\,n}{R} - r_0.$$

It is of course desirable to keep the speed of dynamos low, and yet obtain the full electrical output. As regards the latter point, this in series machines is equivalent to a high external resistance, for the strength of the current is limited by the condition that the armature and magnets should not become too hot. Apart from this, series dynamos are mostly used for arc lighting, and for the satisfactory working of the lamps the current should be as much as possible constant, whatever be the number of lamps in circuit at a time. It will therefore be correct to say that in series machines the output is proportional to the external electromotive force, and consequently it will be a maximum if r is a maximum. We have thus the conditions that n should be as small and r as large as possible. These will be obtained if the magnetic resistance is low, if the number of turns of wire on armature and field-magnets is large, and if the internal resistance of the machine is small. The latter two conditions are to a certain extent contradictory, but by using comparatively large wire a compromise can be arrived at. To make the magnetic resistance low, each of the three terms R_A, R_F, and R_a must be small. By referring to our last article it can be seen that each of these resistances is of the character length divided by area, and that R_a, the air resistance, is by far greater than R_F, that of the field-magnets; and the latter is generally greater than R_A, that of the armature. Consequently a reduction of R_a will have most influence in diminishing the total magnetic resistance. The expression for R_a was found experimentally to be

$$R_a = \frac{1440\ 2\,\delta}{\lambda\,b}.$$

In order to make it small we must have δ, which represents the distance between the polar surface of the magnet and the surface of the armature core, small. We must also have b and λ large. The former represents the length of the armature, which we suppose to be of the cylindrical pattern, and the latter the arc spanned by either pole piece. The product $\lambda\,b$ is the surface of one pole, and to make this large it is evidently necessary to have a large armature. Similar considerations apply to disc armatures, the only difference being that b in this case represents the radial depth of the disc, which has to be taken twice, once for each side, and λ the mean width of pole pieces. A large armature gives a low magnetic resistance of air space—first, because of the large polar surface through which the lines can pass without unduly crowding each other, and secondly because the necessary number of turns Nt can be spread over a larger surface, whereby the thickness of winding, and therefore the value δ is decreased. The lower the magnetic resistance of a dynamo, the less electrical energy is required to excite the field-magnets and the more economical is the machine. This follows also from the above formula for r. In a series dynamo the electrical efficiency μ is the ratio of the external to the total resistance

$$\mu = \frac{r}{r + r_0}.$$

We find from this equation

$$r = r_0 \left(\frac{\mu}{1 - \mu} \right),$$

and substituting this value into the expression for r we obtain

$$\mu = 1 - \frac{r_0 R}{10^{-6}\,T\,Nt\,n}.$$

The larger R, the smaller will naturally be μ, and we find that dynamos with comparatively large armatures are more economical than those with small armatures. In connection with this matter an interesting question presents itself. Suppose we have a series wound dynamo giving a certain output with a certain electrical efficiency, and we wish to make a small model of that machine, what will the output and efficiency of the model be? We suppose that in the model the linear dimensions are reduced in the ratio of K : 1, and that the same numbers of turns of wire are wound on field and armature, but that the gauge of the wire is $\frac{1}{K}$ times that of the real dynamo. In making this assumption we are going probably beyond what is practically possible, for the thickness of the insulation on the wires cannot be reduced in the same proportion as the gauge itself; but in order not to complicate the problem too much we will assume that by the substitution of silk for cotton, and by very careful covering it were possible to make the thickness of insulation in the model $\frac{1}{K}$ times that in the dynamo. We will also assume the workmanship in the model to be so perfect that the clearance necessary for the safety of the armature need only be $\frac{1}{K}$ times that of the dynamo. Since each turn of wire on the dynamo is K times as long as on the model, and since an equal number of turns is employed, the electrical resistance of the model will by reason of the reduction in the total length of wire be $\frac{1}{K}$ times that of the dynamo; but, on the other hand, the area of the wire in the model is only $\frac{1}{K^2}$ that in the dynamo, and this will increase the resistance K^2 times. The electrical resistance of the model r'_0 is therefore K times that of the dynamo. The same reasoning holds good with regard to the magnetic resistance. All the lengths are reduced K times and all the areas K^2 times, making the magnetic resistance R^1 of the model K times as great as that of the dynamo. If we wish to have an equal factor of safety with regard to centrifugal force—which tends to burst the armature—in the dynamo and model, the circumferential speeds must be equal. We may therefore allow the model to run K times as fast as the dynamo. The external resistance through which the model can send a current and excite itself is

$$r' = 10^{-6} \frac{T\,Nt\,Kn}{K\,R} - r'_0,$$

$$r' = \frac{10^{-6}\,T\,Nt\,n}{K} - K\,r_0.$$

Digitized by Google

The first term on the right hand side of this equation is identical with that obtained for the dynamo, and we can also write

$$r' = r - (K - 1)\, r_0.$$

It will be seen that r' decreases rapidly with an increasing K. The efficiency of the model is

$$\mu' = \frac{r'}{r' + r'_0},$$

and, by substituting the values for r' and r'_0, we can express the efficiency of the model in terms of the efficiency of the dynamo and of the factor of reduction K

$$\mu' = 1 - K\,(1 - \mu).$$

This equation is very instructive, because it shows what influence the reduction of the linear dimensions of the dynamos has on the efficiency. The more we reduce the size, the less efficient will be the model, and there is evidently a limit for which $\mu' = 0$, and in this case the model will have just sufficient power to magnetise its field-magnets with short circuited terminals, but it will not be able to do external work. If we reduce the size further, the model will not even have power to excite itself, and it will altogether cease to act as a dynamo. The limit occurs when $1 = K\,(1 - \mu)$.

If we reduce the linear dimensions of the dynamo in the proportion of $K = \frac{1}{1 - \mu}$ its efficiency will be zero, and it will not do any external work.

The same result is obtained from the equation for r' by putting $r = (K - 1)\, r_0$. This gives as the limit of reduction

$$K = 1 + \frac{r}{r_0}.$$

An example will make this matter clear. Say we have a dynamo the armature of which is 5″ in diameter, and which is found to work at its critical condition with an efficiency of 80 per cent. In this case $1 - \mu = 0{\cdot}2$, and $\frac{r}{r_0} = 4$. These values inserted into the above equations for K give both $K = 5$.

If an amateur electrician were to make a model of that dynamo one-fifth the natural size, he would find that he could not get it to work. He would have to increase the size of the armature out of proportion with the rest of the machine in order to obtain a working model.

What has here been explained at some length for a series-wound dynamo also holds good for a shunt-wound dynamo, the only difference being that instead of $r + r_0$ we must insert $r\,s$, the resistance of the shunt coils in the formula for R. It can also be shown that the efficiency depends on the magnetic resistance in the same way as in series dynamos, and that the larger the dynamo the greater is its electrical efficiency.

We need not discuss the question of shunt dynamos at length, because it would be partly a repetition of what has already been said; but it will be necessary to investigate the relation existing between the size of dynamos (series-shunt or compound-wound) and the electrical output they can give without undue heating. This is a more general question of great practical importance, and includes that of efficiency just discussed.

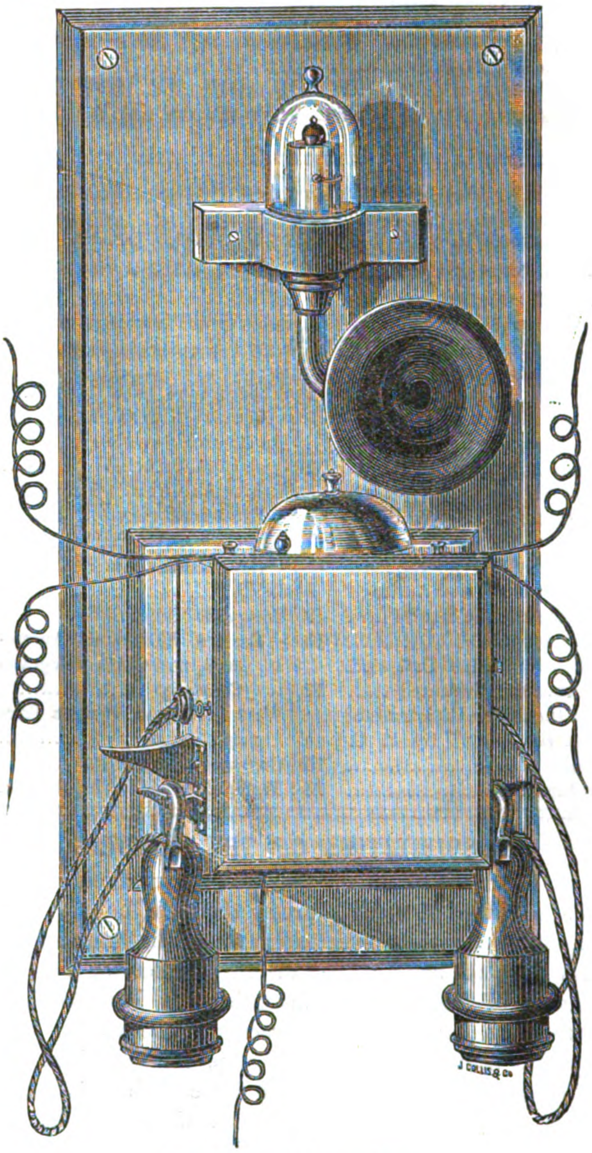
(To be Continued.)

THE THOMPSON MICROPHONE.

In this microphone, the invention of Professor Silvanus Thompson, it is claimed that a diaphragm is dispensed with; but it is open to question as to whether this is really the case.

Of the merits of the instrument itself we are unable to speak with any degree of confidence, in that we have been unable to obtain any more definite information in regard to it than is to be gleaned from an inspection of its exterior. It is probable, however, that the articulation is clear, though necessarily, we think, weak. Its construction will be readily understood from the diagram, a principal feature being the small carbon cone at the top of the instrument, as shown and fitted.

Professor Thompson, like many other people who have gone before him, has apparently been unable to do more than modify existing apparatus. This modification may or may not be, scientifically speaking, a valuable one. We suspect not. Mr. Irish, of Sunderland, exhibited something of the kind a little time ago, but we believe his patent was taken out subsequent to that of Prof. Thompson. We do not mean by this that Mr. Irish was guided in any way by the knowledge which might in that way have accrued to him; far from it. Mr. Irish's microphone, however, was based upon similar but much more ingenious lines.



The Thompson Microphone.

Instead of using a cone fitted as in the Thompson microphone, he employed a small carbon ball about ¼in. in diameter, placed upon three carbon supports arranged in the form of a cone—that is to say, being about 1½in. apart at the base, and approaching to something less than ¼in. at the apex. There was, however, this advantage, the instrument could be reversed and the ball inserted from the broad end of the skeleton cone, or the cone and ball suspended in any desired position, occupying but the space of a few inches, and doing all we can with reason expect from the more elaborate arrangement of Prof. Thompson.

POSSIBILITIES OF THE FUTURE.

If we could but eliminate the solid facts which contribute to the bursting of many a pretty theoretic bubble, through what a vista of roseate anticipation would the future of science be revealed to mankind. Excepting in one or two things, the march of discovery and invention has been too slow to create much excitement. The process, in the natural order of things, has always been step by step, and the minds of men have been so gradually prepared for each benefit conferred upon us by science that the element of surprise has never risen to any great proportions. When Jules Verne wrote his description of the "Nautilus," the strangeness of the idea seized upon everyone. The author had, however, merely collected together a number of theories, both old and new, and by omitting some of the more important causes which would contribute in each case to failure, clothed his conception in a seemingly practical garb. Swift's account of the Island of Laputa was based upon a curiously distorted theory of magnetism, sufficiently *possible* to give it universal interest; and Bulwer Lytton's "Coming Race," in so far as Vril is concerned, turns upon little more than the successful storage of electricity of high potential.

At the present moment we are much given to laughing in our sleeves at the credulity of non-technical people with regard to electrical wonders. We should remember, however, that dreams sometimes come true; that only a few years ago the same sneers and the same scepticism greeted the forecasts of what are now recognised institutions among us; that the impossible is comparative—belonging to an age but not to all time; and that the gift of prophecy attaching to the best of us is constantly baffled by the occurrence of the unexpected. It is not long since a terrible outcry was made about the exhaustion of our coal. People wondered, and wonder to this day, what on earth we are going to do when that familiar and exceedingly dirty mineral sings its death song and resolves its last substance into air. The answer is easily found—we shall burn something else! What? Oh, anything. Petroleum; electricity; hydrogen and oxygen from water. There is plenty of water in the ocean, and we are equally unrestricted as to air. For purposes of locomotion compressed air is getting itself into notice. The loss of coal need not disturb us; when the time comes, we shall be surprised at our own folly, not only for grieving at the thought of its decease, but for ever having used it.

Many strange discoveries, however, will probably greet humanity ages before the collier betakes himself to a more cleanly occupation. It will not be many years, we imagine, before we have a complete and efficient domestic electrical system, lighting and warming our houses, driving the sewing machine, and all other homely appliances; connecting us up with the butcher, the baker, though, for obvious reasons, not then with the candlestick maker; making the coffee and toast in the morning, rocking the cradle at night, and, in fine, doing a thousand and one things that will not only render the demon domestic a creature of the past, but confer upon us a period of rest that will be a foretaste for some and a consolation for all. At intervals along the streets of our great cities we shall have "call boxes," by means of which conversation, by telephone, may be carried on with *any* desired person without trouble or formality; the postman will no longer collect and deliver the letters, a network of pneumatic tubes providing for that. All you then need do will be to drop the epistle in your domestic letter-box and manipulate a knob. When a letter arrives a bell will ring, and the impact of the missive will immediately cause it to be placed in full view upon the hall table. If there is not an abundance of Vril it will be no fault of electricians.

These are only one or two of the things which will happen. Outbreaks of fire will be rendered impossible or harmless. Robbery and violence will be minimised by a thorough employment of the electric light and an excellent system of electrical police calls, placed anywhere and everywhere within reach. A policeman guaranteed on the spot within five seconds. Impossible! Well, perhaps, this is the one thing we are doubtful about. Laputa will be rediscovered. Balloons, electrically navigated, will run regularly between this country and other parts of the world, at reasonable charges; but intending defaulters will notice that in consequence of the recently improved method of telegraphic communication between us and these aerial *voyageurs* there is no additional safety from the clutches of the future cosmopolitan detectives offered by this mode of flight.

This last reflection is saddening. Everything mundane has its drawbacks. Perhaps a general increase of honesty will negative *this* one. We say perhaps, because recent experience seems to indicate that there is just as much right down solid fraud connected with the electrical as with any other industry —and a little more. Dreams, idle dreams. However pleasant a contemplation of the possible future may be found, the stern records of failure which, with the brief chronicles of success, have to be written down on the pages of the world's history,

Digitized by Google

consort but ill with the speculative fancies of an enthusiast. Nevertheless, as we write these lines at the beginning of a new volume, we feel how rash it would be to assert that even the most fantastic of dreams may not be realised before its conclusion. There are already some signs that this may come to pass. Petroleum has lately been successfully tried as a substitute for coal in our steam navigation; and Nordenfeldt's submarine boat bids fair to compete with the "Nautilus" of an extravagant fiction.

CORRESPONDENCE.

HIGH-SPEED ENGINES AT THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The difficulties which have attended the use of many of the high-speed engines at the above Exhibition (professedly an Exhibition of Inventions) have been due, I think, to the inexperience of many of the makers, and to the stiong temptation which such an Exhibition offers to inventors to bring forward crude and untried forms of engine, rather than to anything radically wrong in the principle of high speed.

It is, I think, to high speed in the sense of a great number of admissions of steam per second that we must look for one of the greatest economies in the steam engine of the future.

I have never advocated the highest speeds because I am aware of the difficulties attending their use, but I have plenty of experience of engines running at speeds of 600 revolutions with a stroke of 6in. I believe that such speeds, which are suitable for most modern dynamos, can be economically maintained.

The strains which are imposed upon the parts of high-speed engines are easily calculated, although I agree with you that they are in many cases greater than is supposed. It is to the fact that sufficient cushioning power is frequently not provided, and that the crank has in many cases, as you say, to pull the connecting rod after it as well as push it, that many failures are due, especially where the engine is used in connection with a condenser.

I think that the data which you quote in order to show the difficulties attending high speed are rather unfortunately chosen. They are not, as you say, usual proportions for high-speed engines; but they are very usual ones for locomotives; in fact, the difficulties represented by the use of a stroke of 18in., in connection with a speed of 250 revolutions per minute, are encountered and overcome in designing the great majority of the locomotives in this country.

The cushioning power required in such cases is about half that which is required in the case of my own engines, cited above, the cushioning power required varying as the square of the number of revolutions and as the stroke, if the weights remain constant.

A speed of 390 revolutions per minute and 20in. stroke is by no means unusual in some of Mr. Webb's engines on the London and North Western Railway, and the difficulty in this case of providing suitable cushioning must be nearly three times as great as that in the case which you took for your text last week.

The velocities look rather terrible in decimals of a second, but both engines and engineers rapidly become accustomed to them if—and this is the really important part of the matter—the cushioning question is carefully looked into. In an engine running at 600 revolutions and 6in. stroke the total pressure required to keep the connecting rod on the crank pin amounts, when the crank is turning the centre, to nearly thirty times the weight of the moving parts, and to arrange for this compression economically, in a compound engine and under varying conditions of load, is not always very easy. The engines at the Exhibition were not, as a rule, working under widely varying loads, and in this sense they only met with a part of the difficulties encountered by high-speed engines in practice; but I think that in dealing with the subject you might fairly have given credit to those high-speed engines, and there were several which ran through the Exhibition with as little trouble as their slow-speed neighbours.—Yours, &c.,

P. W. WILLANS.

THE RESISTANCE OF CARBON RODS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can any of your readers kindly tell me where I can get any information about the variation of the resistance of carbon rods with different amounts of current passing, or at different temperatures?—Yours, &c., T.

THE STEAM ENGINE INDICATOR.—VIII.*

BY AMICE.

We may now assume that we are prepared to take an indicator diagram, and to gather from it the indicated power of the engine from which it is taken. Although this is but a small part of the purpose and value of an indicator diagram, we will deal with it first. Later on we shall consider how the information obtained from the indicator can be made available for understanding the behaviour of steam in the cylinder, and for interpreting the peculiarities which determine the efficiency of the steam engine, and the proper design and adjustment of its parts.

We will take as a first example a diagram (Fig. 33) made five years since from one of the last, if not the last, remaining atmospheric engine, and one which, therefore, is of some historic interest. The engine was apparently a Smeaton atmospheric engine, although it had subsequently been improved in some details. It was at work at the Handley Wood coal pit of the Staveley Company until November, 1879, and the date on its cylinder was 1776. It had thus been in existence and at work for the greater part of a century. At the time of its removal an engraving and description of this hoary but hale old relic was published in our contemporary, *The Engineer*, from which this typical diagram of an engine of the low pressure type—a type that did good work—has been copied, and provides us with a fit primary example. The engine had a cylinder 48in.

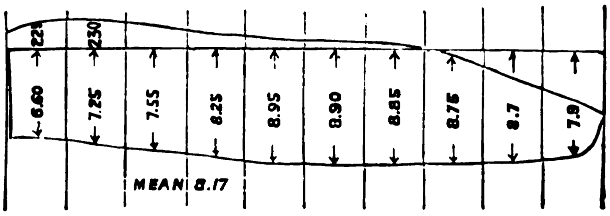

FIG. 33.

diameter, and therefore of 1809·56 square inches area. The stroke was 5·4ft., and during the time the diagram (Fig. 33) was taken the engine made 19 strokes in three minutes, or 6·33 per minute. The steam was supplied by two egg-ended boilers, in which the pressure was about 14lb. per square inch only a few feet from the engine, but, as will be seen, the maximum pressure above the atmosphere was about 2·30lbs. per square inch. The necessary pressure was not great, as all that was done in the steam stroke was to get the piston to the top of the cylinder, and the pumps it worked, in position for the down or working stroke, effected by atmospheric pressure. The diagram has been divided into ten equal parts, and the mean pressure in each part marked therein. From the diagram it will be seen that the steam never rose in the up stroke of the piston above 2·3lbs, cylinder condensation being enormous, while in the first part of this stroke it did not rise even to this. As the piston

* For Art. 7, see *The Electrician*, 28th August, 1885.

Digitized by Google

rose the pressure fell, until, when the piston was at the top of its stroke, exhaust having taken place, the formation of a vacuum had commenced, and in the first tenth of the down stroke had reached 7·9lbs. below the atmosphere, so that the atmospheric pressure was made use of to that extent. This pressure grew, or in other words the vacuum improved, until about mid-stroke it reached 8·95lbs., from which point it fell to 6·6lbs. at the end of the stroke. In this case it is only the vacuum or atmospheric pressure which is credited with doing the work, as the down stroke of the piston is the stroke which raises the water or in which useful work is done, the engine and pump being so nearly balanced that only a very slight pressure should be necessary to raise the piston. The pressure shown above the atmospheric line A L is therefore the friction part of the diagram, and shows the amount of power necessary simply to put the engine and pumps into motion. The ten pressures below atmospheric pressure shown by this diagram, which was taken by a 10lb. spring or a spring which compressed 1in. for each 10lb. of pressure, and thus showed 1lb. pressure for each 0·10in., give a mean of 8·17lb. per square inch, so that the work done upon the piston by the atmosphere in the down stroke, that is in the effective working stroke, was

$$\frac{5{\cdot}4 \times 6{\cdot}33 \times 48^2 \times 0{\cdot}7854 \times 8{\cdot}17}{33000} = 15{\cdot}83,$$

indicated horse-power. The network represented by the water raised by the pumps was 10·05 horse-power, so that the effective work, was of the indicated work, as much as 63·6 per cent. Speaking of this result and of the engine, *The Engineer* remarked :—"Considering the condition of the engine, its disrepair (permitted because its days were numbered), the fact that a 1in. water pipe had to be kept running, nearly full bore, into the cylinder, and about 1ft. of water maintained on the top of the piston, to keep it air-tight. . . . it may be considered that the old engine did not do so badly." Here it must be remarked that the up-stroke of the piston is what is called in pumping engine house language the outdoor stroke, the down stroke bringing the pump bucket up or towards "indoors." This will make what follows clear. After the above diagram was taken "the piston was repacked with a view to lessening the condensation of steam during the outdoor stroke. The hemp was taken out, and some packing with india rubber core put in. With this packing the condensation was less and the vacuum slightly improved, but the tightness of the piston in the cylinder so increased the friction that a much higher steam pressure was necessary to get it out of doors. In a few hours, however, it wore easier, and diagrams, of which the annexed Fig. 34 is an example, were taken." This

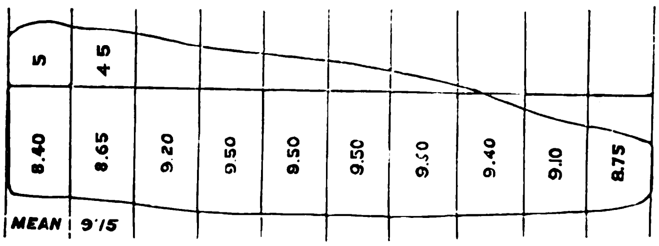

Fig. 34.

diagram we give as affording an excellent example of what may result simply from extra friction caused by tight packing, and of the way in which an increased indicated horse-power may be accompanied by no increase of actual power or of work done. From Fig. 34 "it is seen that with only the same boiler pressure, the pressure in the cylinder is nearly double what it was when so much water passed by the piston during its up stroke. The vacuum is improved, so that the mean effective atmospheric pressure, shown by the indicator diagram, was 9·15lb., the indication of the vacuum gauge reaching 19·5in. Even under these conditions, however, only 17·5 strokes were made per three minutes, or 5·83 per minute. The work done on the piston was in this case, then,

$$\frac{5{\cdot}41 \times 5{\cdot}83 \times 1809{\cdot}5 \times 9{\cdot}15}{33000} = 15{\cdot}80$$ horse-power, or practically the same as before, a result which might have been expected from the recorded experience of the use of atmospheric engines in days gone by, when it was often noticed that what might be called a considerable leakage past the piston was rather beneficial than otherwise." This, it must be observed, was not because the admission of water into the cylinder was itself advantageous, for, on the contrary, it was very wasteful, but it did not cause so much loss as a tight packing in a cylinder that was perhaps an inch out of truth in a length of three or four feet, and very rough also.

These diagrams will afford some idea of the way in which the indicator served to throw light on the work done by atmospheric engines, for, with only about 15 indicated horse-power from the old engine referred to, in its dilapidated state, about 800lbs. of coal were burned per hour, or about 50lbs. per indicated horse-power, representing, with the boilers in use, about 300lbs. of steam per indicated horse-power, or more than twelve times as much as an ordinarily good high-pressure engine of modern make would require. Thus the indicator diagram without other information would show very little. These diagrams might be supposed to show very good performances, and without any knowledge of their history would be considered fairly good, although it is clear from them that from whatever engine, the vacuum is not as good as it should be and that towards the end of the stroke the vacuum decreases instead of being maintained at its maximum. In Fig. 33 it falls from 8·95 to 6·60, indicating a heavy leakage past piston or valves or in the condenser somewhere.

In other words, the diagrams, without full information concerning the engine from which they are taken, show very little more than pressure and its variation, and the difference between Figs. 33 and 34 would indicate difference in external load upon the engine, which is not true, as the difference is only that due to internal friction. With the knowledge of the engine and its condition of working, we see that steam pressure, which should not exceed a few ounces in the up stroke, reaches several pounds; we know that within a fraction all the work done, as indicated by that part of the diagram which is above the atmospheric line, is lost work, inasmuch as the pressure on the up stroke of the piston is not conveyed to or used in working the pump, the connection between engine beam and pump being flexible and incapable of transmitting downward pressure to the pump rods. If the connection between engine beam and pump rods had been rigid, so that the pump rods could have been lightened and required forcing down, and required, therefore, so much less to lift them; or if the beam had been loaded with a weight which in the indoor stroke would have acted in concert with the atmospheric pressure, then steam pressure in the top of the diagram might have done useful work; but this was not the case. The top of the diagram shows nothing but engine friction or lost work. If this top part of the diagram, or rather its amount, be deducted from the lower part of the diagram, the amount of external work done by the engine should be the result. A glance at the diagrams will show roughly that this is the case. The net work represented by the weight of water raised is very nearly two-thirds of the indicated work. If to this net work the friction of the water through the pipes and pump valves be taken into account, the diagrams would agree with the actual work. Or, on the other hand, if we reduce the lower part of the diagram to that which would represent the 10·05 horse-power above mentioned, and then deduct the amount of the top part of the diagram, we should have remaining a small balance of indicated power which would be the equivalent of the friction external to the engine and its connections, or the friction of the water in the pump pipes and valves.

It will be seen that in these diagrams the pressure in the up stroke falls below the atmospheric line, the inertia of motive of the engine and its connections being sufficient to perform the upper quarter of the stroke.

Our first actual diagrams have thus been from the earliest type of engine, engines nominally working with atmospheric pressure only. We shall next deal with diagrams from engines which do not make any use of the atmospheric pressure.

ON THE INSULATION RESISTANCE OF AN EARLY CABLE.

BY F. C WEBB, M.I.C.E.

The figures expressing the resistance of the dielectric of submarine cables have been published as far back as 1859, when, as I have shown in my "Old Cable Stories Retold," Messrs. Siemens and Halske, adopting the Wheatstone bridge with high resistances, measured, by bridge test, the resistance of the dielectric of the Red Sea and India cable.

The insulation resistance of the dielectric of a cable long previous to the bridge test, and therefore much earlier than the test by a Thomson galvanometer, is, however, not so easily to be found. I have, however, succeeded in working out—roughly, it is true—the dielectric resistance of the first two cables laid in 1853 between Orfordness and Schevenengen, in Holland; and the result, I think, will be of interest to electricians, as it shows how vastly superior the insulation obtained now is to that which existed at the above date. I will now explain the process:—

1. Two hundred and thirty-one miles of cable tested for insulation gave 20 degrees deflection on an upright galvanometer with a battery-power of 18 batteries of 12 plates each (or 216 elements).

2. Seventy statute miles of the conductor (which was No. 16 B.W.G. copper wire) gave also 20° deflection on the same galvanometer with one element battery power, that length being selected because it gave 20° from a tabulated statement showing the deflection with one element, with conductor in circuit, taken as every ten miles were added to the circuit.

3. Now, the resistance of a pure copper wire of No. 16 B.W.G. is about 13 ohms per statute mile; but the copper used in cables in 1853 was anything but pure, and, supposing it had a resistance of, say, 33 per cent. more than pure copper—and some coppers tested at even a much later date had just *double* the resistance of pure copper—we may take 20 ohms as the resistance per statute mile of the No. 16 copper wire used in the Hague cables. Consequently, 20 multiplied by 70 gives 1,400 ohms resistance, and this, therefore, forms the resistance for constant; $1,400 \times 216 = 302,400$ ohms, the absolute resistance of the dielectric of the 231 statute miles, and, consequently, $302,400 \times 231 = 69,854,400$, or about 70 megs, as the resistance per *statute mile* at the temperature at which the test was made.

Now, the tests above quoted were taken on the first two Hague cables, when lying under water in the tank constructed by me at Messrs. Newall, Liddell and Gordon's works at Sunderland, in February, 1853. The temperature I cannot give, for we knew nothing in those primitive times about the great difference in the conduction of gutta percha according to the temperature, and, consequently, I never employed thermometers. We may, however, assume that the temperature of the water was about 50° F., and therefore correcting for temperature we get

Log .... 70 $= 1{\cdot}84509$
Log coefficient for temp. 50° F. = $\overline{1}$ 84061

$1{\cdot}00448 = 13$ megohms per statute mile,

or, dividing by 1·15, we get 11·3 megohms per nautical mile.

LITERATURE.

Manual of Telegraphy. By W. WILLIAMS, Superintendent, Indian Telegraphs. Illustrated by 93 wood engravings. [Longmans, Green, and Co. 1885.]

This is a book which has long been needed. It is singular, though quite true, that books suitable for practical men, dealing clearly with practical difficulties, are almost entirely wanting in every branch of applied science. Text books for schools and colleges, or rather for examinations, text books dealing wholly wlth scholastic problems aie as thick as fallen leaves in autumn. The latter books have their uses, but their value is hardly to be compared with that of a really practical treatise. Thousands *believe* they can write a school book—tens might be trusted to creditably complete the task—but few men can be found to attempt the practical works.

Contact with the actual work brings out hundreds of little details that only approximate to theory, leaving an ample margin for personal cleverness to shine. Theory says so and so will happen if so and so be done. Practice says so and so cannot be done, and therefore the theoretical so and so cannot happen. Practice walks, however, in the direction pointed out by theory, gaining a step here and a step there, ever advancing towards the goal, which is still in every scientific application at an almost infinite distance. Theory, then, is one thing, practice is another. The student when he leaves his books and enters the workshop is amazed to find a new field of study opened. He comes to his work expectant, exulting in the thoughts that science has shown how to achieve perfection, only to find experience impotent to overcome practical difficulties arising in every direction.

The book before us deals with the instruments in use, describes their parts and connections, points out their defects and how best to overcome them. It should prove the guide, philosopher, and friend of the initiate in telegraphic work. It is seldom in noticing books that mention is made of the price at which the book is issued; but this seems an exceptional case in all respects. The work has been written under the auspices of the Indian Government, "by order of the Director-General of Telegraphs;" therefore the same strict attention has not necessarily been paid to the merely commercial question as is usual with books of this class. We have no doubt, however, but that the commercial result will amply repay all the care taken in the production of the work. The side notes and references are very copious, the diagrams and illustrations are very good and clear, and the book is well printed. Many books, perhaps, have more illustrations; but in the majority of instances the accompanying text is written to the illustrations, which have been borrowed or bought second hand in every direction. In the work before us the illustrations have evidently been prepared specially to illustrate what the author has to say, and this we emphatically assert is the only method which enables the author to appear in his best manner. We have to thank the Indian Government for giving us the excellent volumes of Schwendler, followed by this of Mr. Williams, which is, if possible, still more valuable.

The book is divided into six sections, each section treating a separate branch of the subject, with an appendix containing two other sections. The practical matter is put first, the laws and principles and the mathematics of the subject being relegated to the appendix. The great value of the work is that it tells you why and wherefore certain directions are given. Thus, in the construction of the Minotti the advantages of sand or sawdust as a diaphragm are discussed. The wire contact with the copper is made by hammering, not soldering, because "the latter would set up local action;" the wire is insulated right down to the disc, "to prevent the bare copper wire being eaten away by the corrosive action within the cell;" the cell should be put into the place it is permanently to occupy before the water is added "to avoid shaking up the solution." These are but a few examples of the care taken to tell the students the "why" of the action prescribed. The section on the setting-up and connecting-up of the various instruments used is excellent, and the diagrams fully illustrate the text. The same may be said of the chapter on testing instruments. We cannot direct attention, however, to each section and sub-section, but may briefly describe what seems to be the plan of the work. The author first treats of definitions and notation and nomenclature, then of batteries and instruments used in practice to perform the signalling; afterwards discussing the instruments used in testing, &c. Telegraphic circuits form an important section, wherein the method is followed of proceeding from the simple to the complex. A chapter on faults is succeeded by one on testing, while, as we have previously said, the appendix treats of the principles and the mathematical proofs of the various formulæ used in practical work. Everything is done throughout the book—both by author and printer—that is

Digitized by Google

calculated to aid the reader to get at the root of the matter. The subject matter of the sentence or paragraph has distinctive type, while the solution of each formula is on a separate page, given with enunciation and proof, like a problem from "Euclid." Probably no other person ever agreed entirely with the matter and method of an author; but we shall be surprised if adverse criticism of any portion of this book is not silenced in the admiration which, on the whole, cannot fail to be given by those who may read it.

UNDERGROUND AND OVERHEAD WIRES.

We illustrate below Brooks's system of underground and of overhead wires. Fig. 1 shows the construction of

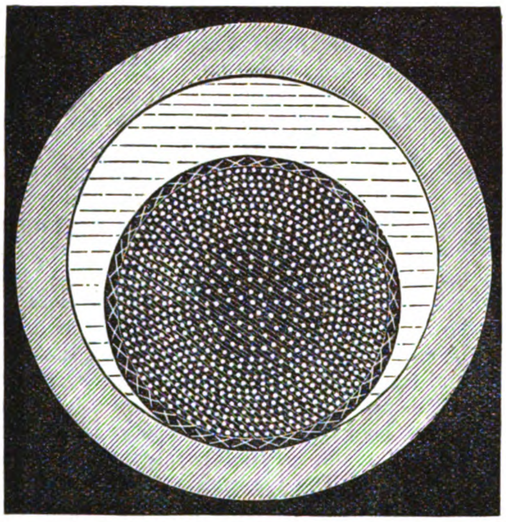

FIG. 1.

a system of 420 telephone wires in a 2¼in. pipe, as laid for the Metropolitan Telephone Company of New York. There is an outside wooden box, not shown in the figure, filled with

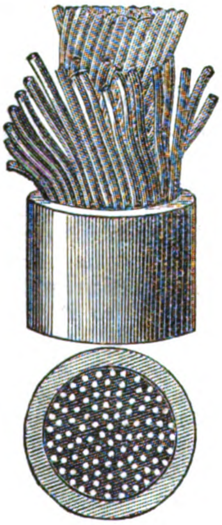

FIG. 2.

FIG. 3.

asphaltum or pitch. The dark shading shows the pitch, filling the box around the pipe. The light ring, next the pitch, represents the wrought iron pipe, inside of which rests the cable, showing the ends of the copper wire surrounded with the insulating oil, which fills the pipe full at all times. Figs. 2 and 3 represent the construction of the Brooks's overhead anti-induction lead covered aerial cable, for telegraph and telephone purposes, carrying 50 and 100 conductors respectively.

AN ELECTRIC GOVERNOR FOR STEAM AND FLUID ENGINES.

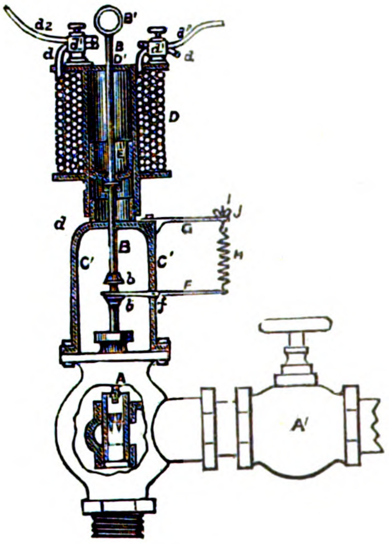
The following interesting description of a new governor appears in the *American Engineer* :—

We herewith present an illustration and description of a new electric governor for steam engines recently patented by Mr. A. L. Ide, the well known engine builder, of Springfield, U.S.A.

The invention embraces the novel feature of adjustability, whereby the governor may be readily adapted to varying requirements of intensity in the electric current by which it is operated. By this means a greater or less intensity in the lights may be obtained, and the number of lamps in the circuit may be varied from time to time, as occasion may require, while the same governor, by means of the adjusting feature referred to, is capable of being adapted to various conditions.

The distinctive feature of the governor valve is its adaptability to close the steam passage by an extreme movement in either direction.

The accompanying cut shows the governor valve located in the steam-supply pipe of an engine, combined with the electric mechanism and adjusting devices by which the position of the valve is controlled in the operation of the electric current.



A is the governor valve, and A' is the stop-valve of the steam-supply pipe. B is the stem of the governor valve. C is the arch. D is a hollow helical electro-magnet surmounting the arch, and E is an armature attached to the stem B, and adapted in form and position to enter the spool of the magnet D.

The engine with which the governor is to be used is supposed to drive an electric generator or dynamo of any form, which dynamo may be used exclusively for the purpose of operating the governor, or it may also be connected to supply any desired number of electric lights, or to do any other form of work for which such apparatus is required or adapted. The method of connecting the helix D of the governor in the current from the generator is sufficiently indicated.

The valve shown has the special feature of being able to close by an extreme movement in either direction. It consists of an open ended cylinder provided with openings through its sides in its middle portion, and seated within two cylindric seats embracing its opposite ends, said seats being cast in the same piece, but separated by a passage by which the steam is admitted around the central portion of the movable valve between the seats, so as to enter the ports, and find escape at opposite ends of the valve. The valve and its seats are inclosed within a globe-shell in the usual manner of this general class of valves. The valve can be operated to partially shut off the steam from the engine by a movement in either direction, and

Digitized by Google

will be perfectly closed when the central ports are brought wholly within either the upper or the lower cylindric seats. The cylinder is of course constructed of such length that when the central ports are brought into either seat so as to close them the other end at the same time protrudes into the opposite seat and cuts off the supply of steam.

In the application of this valve to the purposes of an electric governor, as herein contemplated, it is designed that the ports of the valve shall work in connection with the upper cylindric valve-seat, said ports being closed more or less as the valve is thrown upward by the action of the electric current through the magnet; but it is also contemplated that after the engine is shut down, by closing the stop-valve A' in the usual way the valve shall be forced downward so that its ports are closed within the lower seat. In case the electric current is broken, or in case the driving belt of the engine is broken, the valve will be closed by being thrown downward, so that its ports are carried within the lower seat.

In the construction of the electrical arrangement the helix D is applied to a hollow spool with its axis coincident with that of the valve stem B, being mounted fixedly upon the arch C. The insulated wires *d d* terminate in binding posts *d'*, fixed to the spool, as shown, one or both of said posts being properly insulated from the spool, and both being adapted to receive the wires d^2 d^2, leading to and from the dynamo, and thereby bringing the helix D into the electric circuit of said dynamo. The valve-stem B is provided with the armature E, affixed thereto in proper position with reference to the helix to be raised by the latter when the force of the electric current is augmented therein. Said stem is also provided with the fixed collars or shoulders *b b'*, between which projects the branched end of the lever F, pivoted in the arch C at *f*. The outer end of said lever is connected with the fixed arm G by the contractile spring H, made adjustable as to its tension by the screw-threaded hook I and the thumb nut J.

By depressing the outer end of the lever F the stem B may be raised to bring the valve A into working position, as shown—that is to say, with the ports in the steam space between the seats. Whenever the speed of the engine becomes too great, the corresponding excessive force of the electric current, operating through the magnet D, will raise the valve and brings its ports partly within the upper seat, and thereby proportionately cut off the steam supply and lower the speed of the engine. Said stem is also shown prolonged through the upper end plate D' of the spool (which serves as a guide), and provided at its free extremity with a ring, B', by which also the valve may be raised to working position.

The lower shoulder, *b*, is exclusively used in the operation of the apparatus, being the only one upon which the lever bears by reason of the action of the spring in opposition to the attractive force exerted by the electro-magnet on the armature. The upper shoulder is used when in starting the machine it is desired to lift the valve by bearing down with the hand on the outer end of the lever. By placing the shoulders at a distance apart such as shown, the upper shoulder cannot normally rest on the lever so as to hold the valve up, it being observed that a valve of this class closes by reason of its weight automatically when the current is shut off or broken, and thereby prevents the engine from running away. The ring, when present at at the top end of the valve stem, may, however, be taken hold of and used as a means for conveniently lifting the valve-stem, in place of depressing the outer end of the lever.

In the use of the particular form of valve shown, or of other forms having similar action, should the current be broken the valve falls by its weight, or by its weight re-enforced by the spring H, and closes off the steam supply by carrying the ports of the cylindric valve into the lower seat.

Not only may the required uniformity of engine speed be obtained under varying work, as in other forms of governor, but in the use of the engine for the purpose of generating electricity for illumination the speed of the engine will be lessened or accelerated automatically when a number of lights are shut off or connected into the circuit. By means of the adjusting device applied to the spring H operating through the lever F, as described, a greater or less intensity in the lights may also be obtained, various forms of lamps requiring different intensities of current may be interchangeably used, and the number of lamps in the circuit may be varied from time to time, as may be desired, the adjustable spring being readily varied in its tension so as to control the valve in opposition to currents of differing power.

After the above description of the devices employed a detailed description of the operation is unnecessary. It is obvious that in the normal working of the machine the action of the magnet is to draw the valve cylinder upward, so that its ports will be regulated as to their area, and so as to control the amount of steam admitted to the engine in accordance with the force exerted by the magnet upon the armature *E*, the spring H operating through the lever F to depress the valve and open the ports whenever the force of the current is diminished. While the spring H, however, thus operates in conjunction with the magnetic current, it is plain that when said current ceases, as may happen from a variety of causes, or when a driving belt breaks or is thrown off its pulleys between the engine and the dynamo, the effect of said spring will be to instantly throw the cylindrical valve to its extreme lower position, carrying its ports within the lower seat so as to shut off steam. In other words, the spring H operates to open the ports when the electric current is in action through the magnet D; but in the absence of such current it serves to give the valve a throw of such extent as to close said ports and shut off steam. By using other means to close the valve in case the current is broken or a belt is thrown off, or by omitting all devices for this purpose, the adjustable spring H may be employed with other forms of valve than that here shown, with the same effect as to the variation of force in the magnet D under conditions above mentioned.

It is manifest that a solid core magnet may also be employed, if preferred, with only mechanical modifications of the construction shown.

It is further obvious that the governor described may be applied to control an engine through the medium of a variable cut-off by connecting the armature with the rod or other part operating the cut-off mechanism.

REIS'S ACOUSTICAL TELEPHONE.

[Prof. Houston, in his articles on the Philadelphia Exhibition, contributes the following on "The History of the Telephone," in the current number of the *Journal* of the Franklin Institute, in continuation of articles on the subject. This deals with, so to speak, a special phase of the question, and we therefore give it *in extenso.*]

The radical difference in principle that is claimed to exist between the transmitting instruments of Bell and those of Reis would naturally lead the unprejudiced student to expect to find marked differences in their mechanical structure. Such differences, however, do not exist. On the contrary, limiting the inquiry to a comparison of Reis's various forms of transmitters with those in general commercial use to-day, we will find resemblances of the most marked character, such resemblances establishing the fact we have already insisted on elsewhere, that Bell's contribution to the articulating telephone consisted in the production of a modification of an existing type of apparatus, and not the invention of a new genus.

Since the magneto-electric transmitter, such as described by Bell in his first patent, is in but comparatively limited use, we will exclude such apparatus from the present comparison.

Directing this comparison first to the mechanical structure, and secondly to the manner of operation of the various transmitters, it will be noticed that all transmitters of the type under consideration consist, so far as their mechanical structure is concerned, of three distincts parts, viz.:

1. The speaking tube, or mouth piece.
2. The diaphragm, or membrane.
3. The contact pieces, or apparatus for varying the contact.

In Fig. 10, which in common with Figs. 11, 12, 13, and 14 is taken from the work of Prof. S. P. Thompson on the "Telephone," only necessary parts are represented. The relative positions of the contacts and the diaphragm are, however, clearly shown in all.

In the upper row of sketches, from No. 1 to No. 5 inclusive, are shown various forms of transmitters, designed and constructed by Reis.

Digitized by Google

No. 1 is a sketch of Reis's original human-ear transmitter. The platinum tipped end of the bent lever and its loose contact with the platinum point of the spring, together with their relations to the membranous diaphragm, are clearly shown.

No. 2 is a sketch showing the details of mechanical structure of the transmitting apparatus in Reis's bored-block transmitter, shown in Fig. 3. The platinum contact is attached to the centre of the diaphragm, and has resting against it a platinum point on the end of an adjustable spring. The battery connections and relations of parts to the diaphragm are as indicated.

No. 3 is a sketch of the mechanical structure of the Reis-Legat transmitter, shown in Fig. 5. The long, curved lever attached at one end to the centre of the diaphragm, and furnished with a platinum contact point that is pressed with a regulable pressure against a platinum point borne on the end of an elastic spring, is arranged in the manner shown.

No. 4 is a sketch of the Reis (Hockheimer) transmitter, shown more fully in Fig. 6. The platinum contact points are placed respectively on the middle of the diaphragm, and at the end of the regulable screw.

No. 5 is a sketch of Reis's cabinet form of transmitter, which is shown more fully in Fig. 7. In No. 5, however, the diaphragm is represented, for comparison, as vertical, instead of horizontal as when in use. The heavy vertical line, with the contact point near its lower end, represents the right-angled piece

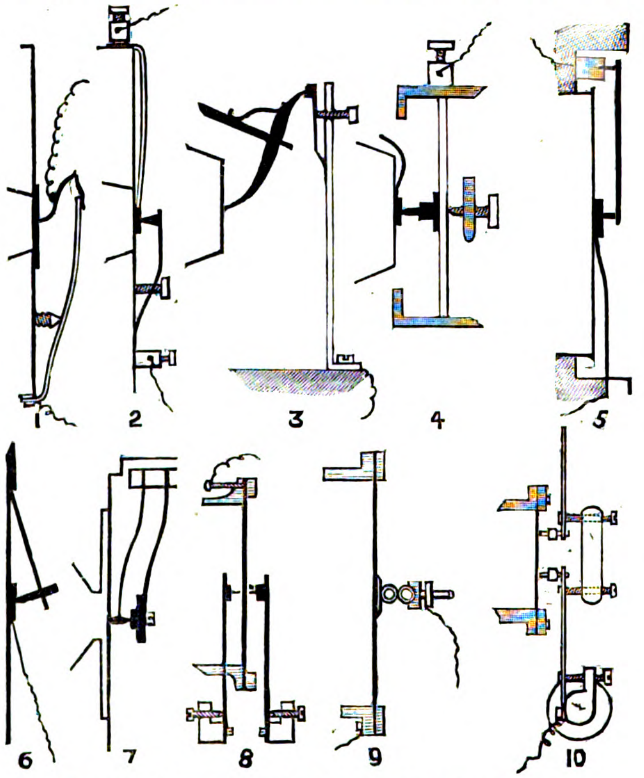


Fig. 10.—Comparison of Reis and Modern Transmitters.

of metal *h*, *g*, *i*, of Fig. 7. Its platinum contact piece rests with variable contact against the platinum point attached to the centre of the diaphragm.

It will be observed that in all of these forms of early Reis transmitters, except the last, means are provided for regulating the degree of contact or pressure between the contact pieces. In the last form, as will be readily understood, no such regulating device is required, since such adjustment is secured by the weight and inertia of the movable or upper contact piece.

No. 6 is a sketch of Berliner's transmitter. As we have not yet described these forms of transmitters, we will give more detailed drawings of the same. In Fig. 11 is shown the essential parts of the Berliner transmitter.

The contact piece *E* is securely attached to the centre of the diaphragm. A second contact piece, *k*, of the form shown, is hung from the arm *I*, which is loosely jointed at *N*, so as to permit the contact *k* to be passed against *E* by the weight of the swinging contact and its supporting arm. The electrical connections are as shown in the figure.

No. 7 is a sketch of the Blake transmitter. A more complete representation of the essential parts of this transmitter, omitting the induction coil, is shown in Fig. 12.

The Blake transmitter, as shown in the drawing, has its mouthpiece formed by a conical hole bored in a block of wood, with the diaphragm in front of the smaller end of the hole, as in Reis's bored-block transmitter. Both contact points are mounted on springs. The first contact consists of a small metallic spike, or pin, of any non-corrodible metal. This contact is thus referred to in the specification of the British patent, viz. :—

"It is desirable that it should be formed of, or plated with, some metal like platinum or nickel, which is not easily corroded. It may be attached directly to the diaphragm, but I prefer to support it independently, as shown, upon a light spring.

The other electrode is attached to a comparatively heavy weight, also supported by a spring, as shown. Of this electrode, the specification states :—"This weight may be of metal, which may serve directly as the electrode, but I have obtained better results by applying to it, at the point of contact with the other electrode, a piece of gas coke, or a hard-pressed block of carbon."

These contacts, with their supporting springs, and their positions with respect to the diaphragm and mouthpiece, are shown in sketch No. 7.

Nos. 8, 9, and 10 are various forms of transmitters devised by Edison, and described or referred to by us in the article on "Edison's Telephonic Inventions." In No. 8 the diaphragm has a contact point on each of its sides; No. 9 shows rubber hose replacing the elastic metallic springs ordinarily employed; No. 10 is an interrupting transmitter, with duplicated contacts.

Comparing the mechanical structure of the above apparatus with one another, it will be observed that Reis's No. 1 or original apparatus contains the three essential portions found in all the others, viz., the mouthpiece, the diaphragm, and the contact points, placed in an electric circuit, and so arranged as to cause their degree of contact, and consequently their electrical resistance, to vary with the movements of the diaphragm under the influence of the sound-waves.

No. 2 closely resembles the Blake transmitter in that one of the contacts is supported on an elastic spring. This is true of all of Reis's transmitters.

No. 4 still more closely resembles the Blake transmitter, as will be seen by the comparison of similar parts in each.

Fig. 11.—The Berliner Transmitter. Fig. 12.—The Blake Transmitter.

No. 5 resembles both the Beliner and the Blake transmitters, in the fact that the weight and inertia of the swinging contact are utilised for producing variations in the degree of contact on the movements of the diaphragm.

The resemblance of Nos. 8, 9, and 10 with the various forms of Reis transmitters will be evident on comparing similar parts.

In all the later forms of transmitters shown, from No. 6 to No. 10 inclusive, the three essential parts of the instrument, viz., the mouthpiece, the diaphragm, and the contact points, are not only present, but also sustain identically the same relations to one another as they do in the original Reis apparatus. Indeed, as is evident, they are in most cases almost exact imitations of Reis's apparatus. As far as their mechanical structure, then, is concerned, a careful comparison fails to reveal any difference between the original apparatus which Reis constructed for the purpose of transmitting articulate speech and the modified apparatus of later days. And yet it is claimed that the former apparati are not true articulating telephones, while the latter are.

Since the transmitting telephone operates mechanically on the electrical circuit, and transmits articulate speech solely in virtue of such mechanical action, if no mechanical differences in the structure of Reis's forms of apparatus can be pointed out by the advocates of Bell, then we submit that they must in fairness recognise Reis as the true inventor of the articulating telephone, and Bell as the modifier only. The description left by Reis of the construction of his various forms of transmitters is, beyond doubt, correct in all its details, and is such as would enable any skilled mechanic to go to work now and produce apparatus entirely similar to those described.

Let us now proceed to the second branch of the inquiry, viz., to the method of operation of the early Reis transmitters. After having given a full and correct description of the mechanical structure of his apparatus, Reis proceeds to explain the method of its operation. Whether such explanation is correct or not, does not appear to us to alter the facts of mechanical structure of the apparatus. If the description left by Reis is such a full and exact one as will enable a skilled mechanic to reproduce the apparatus, and if such reproduced apparatus, without any modification or

Digitized by Google

change whatever, is capable of transmitting intelligible, articulate speech, then Reis invented the articulating telephone, and publicly disclosed his invention in such a full, clear, and exact manner as to enable others to make and use the same, and he therefore must be awarded priority of invention over Bell. Of course, in the preceding it is understood that along with a full description of the mechanical structure of the apparatus the inventor has added an explanation of the manner in which it was to be used. It was, of course, to be clearly stated that the transmitter was to transmit speech and the receiver was to receive it. Such a description is not wanting. The person is to talk or sing against the transmitting membrane, or into the speaking tube, or its vicinity, and the listener is to place his ear near or close to the receiving diaphragm. Nothing else is necessary. Let us, therefore, look into this in connection with Reis's explanation of the manner of operation of the different parts. That explanations as to the method of using the apparatus are not wanting the following quotation will show; for example, in Reis's article, entitled "On Telephony by the Galvanic Current," published in the *Jahresbericht* of the Physical Society of Frankfurt-am-Main for 1860-61, we find the following, viz.:—

"If now tones, or combinations of tones, are produced in the neighbourhood of the cube, so that waves of sufficient strength enter the opening *a*, they will set the membrane *b* in vibration. At the first condensation the hammer-shaped little wire *d* will be pushed back. At the succeeding rarefaction it cannot follow the return vibration of the membrane, and the current, going through the little sprip (of platinum), remains interrupted so long or until the membrane, driven by a new condensation, presses the little strip (coming from *p*) against *d* once more. In this way each sound-wave effects an opening and a closing of the current.

"Tunes and sounds of any kind are only brought to our conception by the condensations and rarefactions of air or any other medium in which we may find ourselves. By every condensation the tympanum of our ear is pressed inwards; by every rarefaction it is pressed outward, and thus the tympanum performs oscillations like a pendulum. The smaller or greater number of the oscillations made in a second gives us, by help of the small bones in our ear and the auditory nerve, the idea of a higher or lower tone."

* * * * *

"The apparatus consists of two separate parts: one for the singing station *A*, and the other for the hearing station B." See Fig. 12.

"The apparatus *A*, a square box of wood, the cover of which shows the membrane *c*, on the outside, under glass. In the middle of the latter is fixed a small platina plate, to which a flattened copper wire is soldered on purpose to conduct the galvanic current. Within the circle you will further remark two screws. One of them is terminated by a little pit in which you put a little drop of quicksilver, the other is pointed. The angle which you find lying on the membrane is to be placed according to the letters with the little whole (hole) *a* on the point *a*, the little platina foot *b* into the quicksilver screw, the other platina foot will then come on the platina plate in the middle of the membrane.

"The galvanic current coming from the battery (which I compose generally of three or four good elements) is introduced at the conducting screw near *b*, wherefrom it proceeds to the quicksilver, the movable angle, the platina plate, and the complementary telegraph to the conducting screw *s*. From here it goes through the conductor to the other station *B*, and from there it returns to the battery.

"The apparatus *B*, a sonorous box, on the cover of which is placed the wire-spiral with the steel axis, which will be magnetic

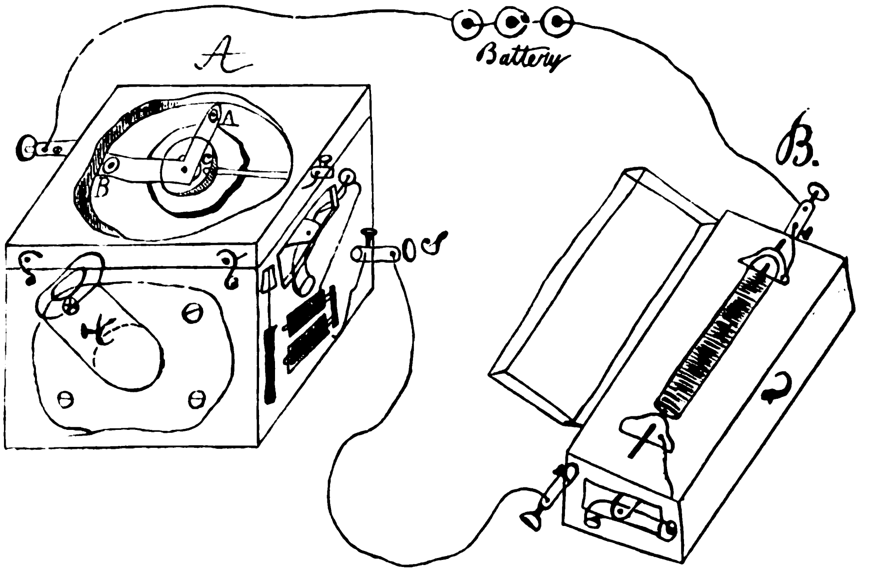

Fig. 13.—Pen and Ink Sketch of Telephone Accompanying Reis's Letter to Ladd.

"But, at every closing of the circuit, the atoms of the iron needle, lying in the distant spiral, are pushed asunder from one another. (Müller-Pouillet, *Lehrbuch der Physik*, see page 304, of Vol. II., fifth edition.) At the interruption of the current the atoms again attempt to regain their position of equilibrium. If this happens, then, in consequence of the action and reaction of elasticity and traction, they make a certain number of vibrations, and yield the longitudinal tone of the needle. It happens thus when the interruptions and restorations of the current are effected relatively slowly. But if these actions follow one another more rapidly than the oscillations due to the elasticity of the iron core, then the atoms cannot travel their entire paths. The paths travelled over become shorter the more rapidly the interruptions occur, and in proportion to their frequency. The iron needle emits no longer its longitudinal tone, but a tone whose pitch corresponds to the number of interruptions (in a given time). But this is saying nothing less than that the needle reproduces the tone, which was imparted to the interrupting apparatus."

Omitting the explanations as to the theory of its operations, the above clearly states the manner in which Reis intended his apparatus to be used. The receiving instrument being placed in the circuit of the transmitter and a voltaic battery, as elsewhere directed, one talks or sings into the mouthpiece of the transmitting apparatus, while another listens at the receiving apparatus. All this precisely as in the case of the so-called modern invention.

So, too, in a letter written in English by Reis, in July, 1863, to Mr. Ladd, of London, which follows.

when the current goes through the spiral. A second little box is fixed on the first one, and laid down on the steel axis to increase the intensity of the reproduced sounds. On the small side of the lower box you will find the correspondent part of the complementary telegraph. [The device here alluded to was a small electromagnetic signalling device, corresponding to the call-bell.]

"If a person sing at the station *A*, in the tube *x*, the vibrations of air will pass into the box and move the membrane above; thereby the platina foot *c* of the movable angle will be lifted up, and will thus open the stream at every condensation of air in the box. The stream will be re-established at every rarefaction. For this manner the steel axis at station *B* will be magnetic once for every full vibration, and as magnetism never enters nor leaves a metal without disturbing the equilibrium of the atoms, the steel axis at station *B*, must repeat the vibrations at station *A*, and thus reproduce the sounds which caused them.

"*Any* (the italics are Reis's) sound will be reproduced, if strong enough to set the membrane in motion."

Here the description of the mechanical structure of the apparatus, the disposition of its various parts, and the manner in which they are intended to be used, are far more explicit than in many patent specifications, and in particular more explicit than the directions to be found in the specification of Bell's so-called telephone patent of 1876.

Besides the above, we quote Prof. Thompson's translation of a prospectus that was issued with the Reis apparatus, sold by Albert, of Frankfort.

Digitized by Google

TELEPHON.

"Each apparatus consists, as is seen from the above illustration, of two parts, the telephone proper *A* (Fig. 14)*, and the reproduction apparatus (receiver) *C*. These two parts are placed at such a distance from each other that singing, or the tones of a musical instrument, can be heard from one station to the other in no way except through the apparatus itself.

"Both parts are connected with each other, and with the battery *B*, like ordinary telegraphs. The battery must be capable of effecting the attraction of the armature of the electro-magnet placed at the side of station *A* (3—six-inch Bunsen's elements suffice for several hundred feet distance).

"The galvanic current goes then from *B* to the screw *d*, thence through the copper strip to the little platinum plate at the middle of the membrane, then through the foot *c* of the angular piece to the screw *b*, in whose little concavity a drop of quicksilver is put. From here the current then goes through the little telegraph apparatus *e*, *f*, then to the key of station *C*, and through the spiral past *i*, back to *B*.

"If now sufficiently strong tones are produced before the sound-aperture *S*, the membrane and the angle-shaped little hammer lying upon it are set in motion by the vibrations; the circuit will be once opened and again closed for each full vibration, and thereby there will be produced in the iron wire of the spiral at station *C* the same number of vibrations which there are perceived as a tone or combination of tones (chord). By imposing the little upper case firmly upon the axis of the spiral the tones at *C* are greatly strengthened.

"Besides the human voice (according to my experience) there also can be reproduced the tones of good organ pipes from *F*—*c*, and those of a piano."

A careful consideration of the preceding quotations will render it clear that no objections can be found with the descriptions that Reis gives of the mechanical structure of his apparatus, nor of the manner in which it is to be used in the transmission and reproduction of *all kinds of sounds*, including, as is repeatedly claimed by Reis, articulate speech. Nor, indeed, are we aware that any such objections have been urged, unless it be the very remarkable one that Reis never intended his apparatus for the transmission of speech, but only for the transmission of musical sounds—a statement of marvellous assurance, in view of the very explicit statement of Reis that his apparatus was designed to transmit speech, and that such speech was actually transmitted. The argument made by the advocates of Bell against the claims made for Reis as to the invention of the telephone refers almost entirely to the theory of its actions as advanced by Reis in the preceding quotations. It is insisted that the makes and breaks referred to by Reis were absolute and complete, and were followed by absolute and complete cessations of the electrical current in the circuit of the transmitting and receiving instruments. That such currents cannot by any possibility act to reproduce articulate speech, and since, as they claim, Reis intended to describe such makes and breaks, his apparatus never could have transmitted or reproduced such speech.

It never seems to have occurred to such objectors that if even the smallest possibility of misunderstanding existed as to Reis's interpretation of the words "make" and "break," a spirit of but ordinary fairness would have led to the inquiry as to whether the original Reis apparatus would transmit articulate speech as he and others claimed, in which case it would appear that either,

1. The assumption made by them that makes and breaks, complete and absolute, cannot transmit articulate speech is untrue; or,
2. That Reis did not intend to convey the same meaning by his use of the words makes and breaks as they assumed him to do, but that the makes and breaks were the variations in the electrical resistance of the circuit that exactly corresponded to the variations in the movements of the transmitting diaphragm when acted on by the impinging sound waves, or, as Reis says in the *Jahresbericht* article, "to set up vibrations whose curves are like those of any given tone or combination of tones;" or,
3. That, although the description given by Reis of the manner in which his apparatus actually operated was inaccurate, yet the mechanical structure of the apparatus, the relative proportions of its parts, and the method in accordance with which they were intended to be used, were such as would enable them to do all that their inventor claimed.

That very grave doubts fairly exist as to the meaning Reis intended to be given to his use of the words "make" and "break" there can be no question. The mechanical structure of the apparatus itself, and the masterly manner in which Reis, in the *Jahresbericht* article, considers the nature of the curves in the case of compound sounds, prove beyond reasonable doubt that he clearly understood the principles according to which the telephone transmitter varied the intensity of an electrical current, so as to permit it to reproduce in the receiver the sounds made at the transmitter.

The matter will, perhaps, be made clearer by an examination of the Reis and other transmitters, shown in Fig. 10, while discussing the method in which they act while in actual operation.

(To be continued.)

* This figure practically represents the perspective view of Fig. 13.

THE NEW SUBMARINE CABLE FOR THE PERSIAN GULF.

Letters have been received from Suez descriptive of the severe gale encountered by the "Dacia" in the Bay of Biscay from the 8th till the 10th of October on her voyage out to the Persian Gulf. She sailed from the Thames on the 6th, followed two days later by the "International," and besides her officers and crew had on board the chief of the expedition, Colonel Bateman-Champain, R.E., Director-in Chief of the Indo-European Telegraph, for the thorough efficiency of which department as a means of communication between England and the East the country is chiefly indebted to Colonel Bateman-Champain himself. There were also on board the "Dacia" Sir Henry Mance, C.I.E., electrician of the Persian Gulf cables; Dr. Denis Scully, of the Persian Telegraph staff; and a few passengers accompanying the expedition, among whom were Colonel G. A. Leach, R.E., Land Commissioner of England.

The weather was stormy when the "Dacia" sailed, and the friends who assembled to wish God speed to the expedition could not but think of the unlucky history of the last Persian Gulf cable, laid in 1868, after having been abandoned and salvaged in the "Calcutta" during a terrific gale in the English Channel, and after the P. and O. steamer "Carnatic," with Colonel Bateman-Champain on board on his way to superintend the laying of the cable, had been wrecked, and upwards of 60 of her passengers and crew had perished in the Red Sea.

The following extracts from a private letter from Colonel Bateman-Champain to a friend in England show how near the forebodings about the previous expedition were to being realised:—

"Steamship 'Dacia'—When we woke up this morning (8th October), things were looking gloomy. A strong wind was blowing straight in our teeth as we steered for Ushant, and we hardly made any progress. Of course, too, it rained hard at intervals, and was cold, while the ladies and landsmen were showing decided symptoms of sea-sickness. The ship, however, was amazingly steady, considering the sea was pretty rough, and all I felt sulky about was our slow speed. The wind kept on rising and, of course, the sea likewise. In the evening (8th) a regular gale came on, and all we could do was to lie to, head to wind, and ride it out. We pitched and rolled a good deal, and the sea began to wash over our decks, so that it was rather difficult to get to and from my cabin. Once I got a green sea right over me, and had to change every rag. Altogether the 9th was a miserable day, and there was no sign of the tempest abating. That night we had almost a hurricane. A wave carried away one of my windows, after I had turned in, and set my cabin awash, but I could not join the others for fear of being swept overboard on the journey aft. About midnight one of our boats was washed away, to our immense disgust, because if picked up with 'Dacia' plainly painted on her you poor people would imagine the worst. Friday night was the worst, but Saturday was bad enough, and by this time the sea was terrible. It broke through the skylight into the saloon, and we had to batten down all the hatches and sit through the day by lamplight. To go on deck was hardly possible, as it was continually under water, but I persevered in sleeping in my deck cabin, the water splashing about as I lay in my berth. At 6 p.m. the skipper, Captain Barker, thought he saw some improvement, and determined to stand on our course, and then didn't we roll! We nearly lost another boat, and had a miraculous escape of a collision. Just after dark a strange steamer ran across our bows, scarcely 100 yards away, and one half minute would have settled us both. Moore (one of our cable hands), twenty years at sea, vows he never before was so near his grave; but he is rather a croaker. Still, it wasn't nice, as no boat could have lived a minute in such a storm. Sunday, the 11th, was much better, the sea tremendously rough, but we felt that we were doing something instead of helplessly lying to and waiting for a change which wouldn't come. We had frequent squalls, and a strong wind on our beam, but got away, and began to think of drying ourselves. Monday morning saw us out of the Bay. Tuesday was lovely, and to-day (Wednesday, 14th) it is just perfect. The ship is cleaned up, and all is peace and joy. What a change! I never met with better shipmates. The captain and officers are excellent, the crew are clippers, and the cooks and stewards are as obliging and smart as men can be. The kitchen is as clean as a dairy, and the food excellent. In short, we are in clover, and I trust that now our troubles are over. We signalled yesterday from Lisbon to relieve anxiety. October 23, 4 p.m. Arrived all jolly at Port Said. 25th, in the Canal, 3:15. Here we are stopped to let a P. and O. pass. 9 p.m.—Here still. Another little misadventure has occurred, which might have proved disastrous. You must know that in the canal there is not width for two ships to pass, but every seven or eight miles are stopping places, where the outward or homeward bound vessel, as the case may be, ties up to the bank to let the oppositely directed vessel go by. We had first to tie up, and when the 'Verona' and 'Vectis' had gone by they had to do the same to make room for the 'Tangier,' a great big heavy ship which was following us. As another Dutch ship was coming north from Suez neither we nor the 'Tangier' could go ahead, and it was the 'Tangier's' business to make fast between the 'Verona' and us till the 'Dutchman' passed, and then we could all start again. I was standing on our quarter-deck watching the 'Tangier' steering straight at us, and I observed to Dr. Scully, 'if that Tomnoddy doesn't go astern

Digitized by Google

he will be into us.' On he came, slowly but surely. We could not move, being securely made fast to posts, so all we could do was to helplessly watch the collision. The 'Tangier' ploughed on, neither going astern nor steering clear, and scraunch she went through our best little boat, grinding it to smithereens, then scraunch through our bulwarks, and had she been moving a bit faster she must have cut us in two. Of course, we personally were safe enough if no mast or gear fell on our heads; but fancy all this cable and paraphernalia being swamped, and having either a month's delay or the whole job to do again. Luckily no very serious damage has been done. We shall botch up the ship's side and start again to-morrow morning. The 'Tangier's' people will have a nice little bill to pay, as the fault was entirely due to their pilot. The truth seems to be that these pilots, all French and Italian, lose their heads at the least hitch, get excited and helpless, and come to grief. The 'Tangier' man should take to plumbing and glazing, for a more inexcusable accident could not be imagined. The 'Tangier' hit the 'Dacia,' and we could not get apart for more than an hour"—*The Times.*

LEGAL.

In the Chancery Division of the High Court of Justice, before Mr. Justice Kay, the case of Cooper *v.* Slatter came on for hearing yesterday.

It was a dispute between two electrical engineers, who, while arranging the terms of a partnership, obtained two valuable contracts—one in connection with the Rosario Railway, and the other from Messrs. Bailey, Hawkins, and Co. On the eve of signing the necessary documents to complete the partnership differences arose, and they separated; whereupon Mr. Slatter claimed to be entitled to execute the contracts. Mr. Cooper contended that the defendant was not competent to complete them, and urged that the second contract named was obtained by the plaintiff on the introduction of a member of the firm of Sir Charles Fox and Co.

The JUDGE decided to appoint Mr. Slatter as receiver and manager, to carry out the contracts until the trial of the action, the defendant giving the necessary security.

COMPANIES' MEETINGS & REPORTS.

Eastern Extension, Australasia, and China Telegraph Company (Limited).

The twenty-fourth ordinary general meeting of this Company was held on Tuesday, the 10th inst., at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting, and signed by the Chairman. The report of the Directors, which has already appeared in *The Electrician*, was taken as read.

The CHAIRMAN: Gentlemen, you have in the report a very full account of the Company's working during the last six months. However, I shall, as usual, make some remarks upon the report which is in your hands. The gross receipts for the half year have amounted to £259,476, against £237,672 for the corresponding period of 1884, showing an increase of £21,804. The working expenses for the same period have been £74,418, against £66,658 for the corresponding half of 1884, showing an increase of £7,760, which is more than accounted for by the loss in connection with that unfortunate vessel the steamship "Magneta." That vessel, as stated in the last report, was fully insured; but the Company, in accordance with its usual practice, underwrote half the value of the cable on board, and the loss upon this, together with the payments to the relatives of the crew and the expenses of the ship's fittings and those incurred during the voyage, amounted to nearly £10,000, as shown in the accounts. This, as you will see, we have charged against the revenue of the past half year. The net revenue for the half year was £140,358, against for the corresponding period of 1884 £127,415, showing an increase of £12,943. The usual dividend at the rate of 5 per cent. per annum, together with a bonus of 2s. per share, making a total payment of 3½ per cent., has been paid for the last half year, and the balance carried forward, after charging a further sum of £20,000 towards the cost of renewing the Singapore-Saigon and the Penang-Rangoon cables, is £32,858. In regard to the Singapore-Saigon and the Penang-Rangoon cables, it was anticipated that the whole of the operation would be finished before the 30th of June, so that the cost would be shown in the accounts under review. But it was not found convenient to pick up the whole of the old cable till after the close of the half-year and consequently the final figures will be given in the accounts of the current six months. No fresh renewal has been carried out in the half year, but your Directors have decided to pick up the cable—400 knots in length, laid in 1870 between Singapore and Penang, which has for some years past, and especially of late, been much interrupted, necessitating frequent and costly repairs—and put down a new brass-ribboned cable in its place. Although we have to incur the cost of this renewal of the cable, we expect at the same time to get rid of a very considerable annual outlay on repairs. Moreover, the cable we pick up is not lost. We re-serve it, and put it into stock at Singapore, using it as occasion requires. For instance, last year with the cable we had at our command we were able to meet the requirements of H.M. Government indirectly through the Telegraph Construction Company, by laying a cable to Port Hamilton at a time when the Government urgently required the connection. Consequently, while it appears that we are spending a considerable sum of money in relaying these cables, we have generally found that in the end there has been no loss. I may mention that the Port Hamilton cable has since been broken, but we expect it will be in working order shortly. Since I addressed you last we have had a new steamer built, called the "Recorder," to replace the one lost. We have never heard any account whatever of the "Magneta." It is one of the most remarkable things that have ever occurred—that a vessel so well found in every way should have so entirely disappeared. I may mention that the recorder is the name of the valuable instrument invented by Sir William Thomson, one of the greatest electricians of the age, and, probably as an instrument, it is the nearest approach to human action that has been yet introduced into electric telegraphy. We thought it was only a proper compliment to pay to the great electrician that we should name this ship after his most important and valuable instrument. The ship is now lying in the Thames, and probably a more complete ship has never been fitted out for the purpose. She will proceed shortly to Singapore, and I hope will prove of valuable service to the Company. But, as I have often mentioned, the less our ships are employed the better for the Company's interests. I think these are the chief points connected with the working of the Company. But there is another question which I daresay many of you will be interested to hear something about—namely, as to what occurred at the Telegraph Conference at Berlin the other day. A great deal appeared in the newspapers in regard to that Conference. I may first of all tell you that the Submarine Companies at these Conferences have no votes, but are allowed to speak, and we must, therefore, through moral suasion, influence the different delegates representing the various States. Unless, therefore, our arguments are based upon justice, you may be sure that we should not carry our point. The President of the Conference, Dr. von Stephan, whose great object was to get the rates reduced as much as possible, recognised the value and importance of submarine cables, which, having their origin in England, have given to the States of Europe the same advantages which England derives; and in these days, when the European States are looking all round for new countries to colonise, you can well understand that they take a lively interest in submarine telegraphy, and that they try, as far as their influence and power go, to reduce our rates as much as possible. We, therefore, as a company, or a combination of companies, had practically to fight the European States. But when I tell you that the companies own 98,450 miles of submarine cable, costing £34,460,000, while the Governments own only 7,300 miles of cable, costing £1,460,000, and that the value of the companies' cables exceeds that of the whole of the land lines belonging to all the States of Europe, you will understand that our position at the Conference was a very important one, and one which we had to defend with all the intelligence and influence we possessed. There was one very important point that we dealt with at the Conference, and that was how far we could reduce our rates. The Eastern Extension Company have for some time been considering the necessity of reducing the rates to Australia. Why? Because we found that there was a considerable amount of vitality in the Australian traffic, and by a reduction we felt we could increase our receipts in the course of a few years to such an extent that we should recoup the first loss. But we felt that India, which is a party to this system, should take a share in the reduction. I therefore announced, on the part of the companies, that I was quite prepared to make a reduction provided that India and South Australia accepted their proportions. The South Australian Government at once agreed, and I may mention that their delegate telegraphed to Australia, and so promptly was his message attended to that I think in ten hours we had the reply that they were prepared to reduce their proportion. The Indian Government, on the other hand, replied that their exchequer could not afford it, and declined. I was then urged very strongly to give the reduction unconditionally, but I refused, because I had the Australian colonies as a lever to act upon the Indian Government, and I was not going to give up the opportunity which I had been labouring for for the last two years to get the Indian Government to reduce her high transit rate across India. I will give you a little idea in regard to what I call one of the hardships which the Australian people have to submit to from the charges of the Indian Government. If we had the same arrangement with the Indian Government for the transmission of our international messages across India that we have with the English Government—that is, having a special wire, and paying so much for it—the difference would be that we would pay the Indian Government £3,500 a year, whereas now we pay £40,000 a year. If we were to get that reduction it would enable us to give the Australian colonies a reduction of 2s., in addition to the 2s. we were prepared to give them. That is the position we are in at the present time. We are endeavouring to bring pressure on the Indian Government, and are being supported by the Australian Agents-General in the object we have in view, and I am hopeful, before I meet you again, that we shall have carried our point, and thus largely benefit Australia, which is entitled to consideration, without seriously affecting the receipts of the Company. The estimated loss by the reduction, if carried out, both to India and China will not exceed £40,000 a year, and I believe we shall soon be able to recoup that. Meantime, you will, I believe, receive your dividends from time to time as you have hitherto done unless some unforseen circumstances arise. I have now given you at some length an outline of what was done at the Telegraph Conference. The next Conference will meet in five years' time, and I hope, until then, we shall be comparatively at rest. But I say this publicly, that we must always bear in mind that we have to pay dividends, and that we ought rather to be moving upwards than downwards. We shall, however, endeavour as far as possible, when we see a decided growth in the traffic, to make such reduc-

Digitized by Google

tions as we are warranted in making without injuring the Company's interests. We have to pay dividends, but Governments have not. Many of the land telegraph systems of Europe do not pay, and consequently they have to draw upon their exchequers. But we cannot do that. I think with the position we occupy now we give a service perhaps second to none, and there is not much possibility of any competition arising. Competition may of course arise, but it cannot do the work cheaper or so well as we are doing it. I think I have now touched upon all points of interest to you. I may, however, mention one other matter, and I think I may do so good-humouredly, namely, that we have a right to complain of want of courtesy upon the part of some of the Press. For some years we were unable to induce the German Government to make a reduction in the Press rates for Australia, although quarter rates have been given over the Extension Company's lines for a long time past, and it was the wish of my colleagues and myself that the reduction should apply to the whole system between England and Australia; but we were never able to get permission to carry it out. At the very first interview I had with Dr. von Stephan, when he was proposing certain reductions, I said: Sir, for years you have stopped progress in telegraphs; but you are now making a new departure. Your desire is to reduce rates and increase traffic. Now, the first thing I ask you to do in the interest of the Press is to reduce to quarter rates. He could not get out of it, gentlemen, and he admitted it. While we have been blamed by the Press for refusing to make large concessions, I have never heard one compliment paid to us for the enormous advantages which we give to the Press. When the Press of Australia were hitting us very hard because we would not give up 1s. 6d. as India would not give up 3d., they might have admitted that they were getting this concession; but they did not do so, and I complain that we receive no support from them. I hope the Press will take these few remarks good humouredly, and that they will help us when we are entitled to help. He concluded by moving the adoption of the report and accounts.

The Marquis of TWEEDDALE seconded the motion.

Mr. JOHN NEWTON observed that about a couple of years ago the Chairman led them to expect a great accession of telegraphic business through the opening up of China, and he wished to know if there was any greater prospect of the development of telegraph business from that cause. In China they did not appear to talk so much about depression of trade as we did, and he was rather disposed to think that there was not so much reason for it in the far East.

The CHAIRMAN: Probably there is no country at the present time that wants more money than China does. If the Chinese give contracts to European contractors for making railways—and they are moving in that direction—it will be an enormous benefit to our telegraph system. They are, as I have said, moving in that direction, and we only hope that they will move quickly. He then put the resolution, which was carried unanimously.

A SHAREHOLDER: In the event of the Indian Government not agreeing to your proposal you will, I suppose, have to carry out your reduction as regards Australia?

Mr. GRIFFITHS: No; they are willing to give the reduction to Australia when India makes the concession referred to by the Chairman.

The CHAIRMAN: This is not the first time this question has been put to me, and I may as well reply to it. Since I returned from Berlin I have had an interview with the Australian Agents-General, and they put the very question to me which the honourable shareholder has just asked. I said to them: "If I were to say to you, 'Yes, we will give you these reduced tariffs,' you would put your hands in your pockets and not try to get anything for us. You have a prospect of getting an additional 2s. to what we are prepared to give you, if you get this concession from India, and I wish you to work for it. I am not going to throw away this lever till I think there is some action on the part of those who will so greatly benefit by the reductions we propose." That was my reply.

Mr. HEIRON thought it was the duty of the meeting to pass a vote of thanks to the Chairman for his clear and able speech in making the statement which he had just addressed to the shareholders of the Company, which was one of the most important telegraph companies in the kingdom. It afforded him very great pleasure in proposing a vote of thanks to the other Directors as well for their able management of the Company's affairs.

Mr. GRIFFITHS, in seconding the motion, said that no one could have listened to the Chairman's speech without being convinced of the ability brought to bear on the management of the Company's business. They were prospering, and there was no doubt that their prosperity was to a great extent attributable to the able conduct of their affairs.

The motion having been carried unanimously,

The CHAIRMAN said: Gentlemen, I am much obliged to you for the compliment you have paid to my co-Directors and myself. You may rest assured that our interests are your interests, and that you stand in a better position to-day than you did before we went to the Conference.

The proceedings then terminated.

The West India and Panama Telegraph Company (Limited).

Report of the Directors for the six months ended June 30 last, to be presented at the seventeenth ordinary general meeting of members, at the Cannon-street Hotel, on Wednesday, the 18th inst., at three o'clock:—

The amount to credit of revenue is £51,012. 1s. 7d., and the expenses have been £28,038. 11s. 8d., leaving a balance of £22,973. 9s. 11d., which, with the balance of £500. 2s. 10d., brought from last account, makes a total of £23,473. 12s. 9d. Of this sum the Directors have placed £6,000 to reserve, leaving an available balance of £17,473. 12s. 9d., with which it is proposed to deal as follows:—

	£	s.	d.
Payment of 9s. per share on account of arrears of dividend on the First Preference shares	£15,553	7	0
Balance to current half-year's account..............	1,920	5	9
	£17,473	12	9

The traffic receipts for the half year show an increase of £2,459. 1s. 2d. over those of the corresponding period of 1884, attributable to a lesser number of interruptions, and to the disturbances in Colon during the month of April last. The ss. "Duchess of Marlborough," which came home in July to be refitted and supplied with a new boiler, has been thoroughly overhauled in accordance with Lloyd's requirements, and has since returned to St. Thomas with 77 knots of new deep-sea cable, manufactured by W. T. Henley's Telegraph Works Company (Limited). In order to proceed with the repairs of the original Jamaica-Santiago de Cuba section referred to in the last report, and to meet any other contingencies, a contract has been entered into with Siemens Brothers and Co. (Limited), for the manufacture of 250 knots of deep-sea cable, and the Company's ss. "Grappler" is on her way home for the purpose of carrying out this cable. Several sections of the Company's line were interrupted during the period under report, but they are now in good working order.

Business Notices.—Mr. H. C. Harold, of 30 and 31, St. Swithin's-lane, E.C., has, we are informed, been appointed the sole agent for the sale of the electric light carbons, battery plates, and electrodes manufactured at the works of the Liepmann Carbon Company (Limited), Millwall, E.—Messrs. Paterson and Cooper inform us that after the 16th inst. their offices and show rooms will be removed to their works at Pownall-road, Dalston, owing to the termination of their lease at Little Britain. The Dalston premises are situated close to Haggerston Station, some ten minutes by rail from Broad-street.

NOTES.

THE WAR WITH BURMAH.—A telegram from Thayetmyo, dated November 18, says that the telegraph was found working to Mandalay.

TELEGRAMS FOR BULGARIA, &c.—It is notified that telegrams for Servia, Bulgaria, and Roumelia can now be accepted only at sender's risk.

CENTRAL ASIAN TELEGRAPHS.—A telegram dated St. Petersburg, November 19, announces the completion of the telegraph line between Merv and Penjdeh on that day.

INDIAN AND COLONIAL EXHIBITION.—H.R.H. the Prince of Wales, President of this Exhibition, has approved of the *Journal* of the Society of Arts becoming the official organ of the Exhibition.

THE EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY. This company publish the numbers of 1,203 five per cent. mortgage debentures of £100 each, which have been drawn for payment at par on 1st January, 1886.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th November are £1,827, as compared with £2,170 in the corresponding period of 1884.

SALES OF PLANT AND APPARATUS.—Particulars will be found in our advertisement columns of two interesting sales of valuable mechanical plant and electrical apparatus, to be conducted next month by Messrs. Wheatley Kirk, Price and Goulty.

A VACANT CHAIR.—The position of Professor of Experimental Physics in the University of Sydney, recently occupied by Prof. John Smith, C.M.G., M.D., LL.D., &c., is vacant in consequence of his death. The salary is £900 per annum and one-half of the fees.

THE ELECTRIC LIGHT IN SWEDEN.—Strehleuert and Co., Sodertelge, have established the first manufactory in Sweden for electric lamps. It is constructed after the American pattern, and is managed by electricians, &c., who have had several years' experience in the United States.

ELECTRIC SIGNALLING FROM BALLOONS.—The current number of *Electricité* contains an account of some experiments in electric signalling from balloons, carried out by MM. Mangin and Royer. The experiments are identical with those of Mr. E. Bruce, recently described in our columns.

THE CREIL EXPERIMENTS.—Criticising the recent experiments of M. Marcel Deprez, M. Hospitalier says that the more he examines the results submitted to the Academiè des Sciences on the 26th ultimo, the less he is able to understand the enthusiasm which they have called forth. We are of precisely M. Hospitalier's opinion.

THE TELEGRAPH BATTALION.—A committee is now considering the question of the employment of pensioners and reserve and discharged men of the Telegraph Battalion in the service of the General Post Office. Should their recommendations be carried into effect, an opening will be given to those men who, on leaving the service, are considered eligible.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—A meeting of this society will be held at the Institution of Civil Engineers, 25, Great George-street, S.W., on Thursday, Nov. 28, 1885, when the following paper will be read, "On the Necessity for a National Standardising Laboratory for Electrical Instruments," by J. A. Fleming, M.A., D.Sc., member.

ANOTHER EARTHQUAKE IN CASHMERE.—A Reuter's telegram, dated Bombay, November 16, says that the inhabitants of Srinagar, Cashmere, have again been thrown into a state of alarm and consternation at the recurrence of earthquake shocks there. The first shock, a severe one, was felt on the night of the 15th, and this has been followed by a constant series of slighter ones.

THE PERSIAN GULF CABLE.—We are informed that the steamers "Dacia" and "International," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company, were at Jask (Persian Gulf) on the 14th inst., and the laying of the new Persian Gulf cable commenced on the following day, under the direction of Colonel Bateman-Champain, R.E., assisted by Sir Henry Mance, C.I.E.

THE ELECTRIC LOCOMOTIVE AND POWER COMPANY.—On Tuesday last we were invited by this Company to witness a trial of their electric tram engine, which was announced to take place at the North Metropolitan Tramway Company's depôt at Stratford, E., on the same day. As on other occasions, however, when sufficient notice has not been given us, we were compelled to decline the invitation.

THE ELECTRIC LIGHT IN DENMARK.—The first establishment lighted throughout by the electric light in Denmark is the beet-sugar manufactory at Nykjobing, on the island of Falster. The number of lamps is 200, of 16 candle-power each. They are manufactured at Mr. Förgenser's establishment in Copenhagen. The sugar manufactory is only in operation for the winter quarter, but the lamps will be needed from 14 to 16 hours out of the 24.

THE BECHUANALAND TELEGRAPHISTS.—Major Jelf arrived in England from Cape Town on the 5th inst., and a contemporary is informed that the section of the Telegraph Battalion from Bechuanaland will arrive home towards the end of the present month. The following men of the 2nd Division have been nominated as military telegraphers to remain in Bechuanaland with the police force:—Lance-Corporal Jones, Sappers Hepworth, Craddock, Lewis, Ancell, and Tutin.

BLEACHING BY ELECTRICITY.—Cotton manufacturers in St. Petersburg are said to be becoming much interested in the application of electricity for the purpose of bleaching cotton and flax fibres as well as tissues. The material is steeped in water, which is then decomposed by electricity, the oxygen which is thus set free at once acting on the fibres. This process, which has already been described in our columns, has been found to occupy very considerably less time than the ordinary one.

PROPOSED TELEPHONE FOR BATH.—At a meeting of the surveying committee held recently, prior to the election of mayor, the clerk read an application from the Western Counties and South Wales Telephone Company, stating their intention, if sanctioned by the Corporation, to open their overground wire exchange system in Bath and to connect Bath with Bristol by trunk wires. The question was deferred to the next meeting, the clerk to write and ask for a plan, and also for the attendance of Mr. Lewis, the general manager.

EXPOSITION DU TRAVAIL, PARIS.—The awards in the sixth section—Electricity—of this Exhibition are as follows:—Gold medals: MM. Lévy, Radiguet, and Aboilard. Gilt medals: MM. Arnould and Vauzelle. Silver medals: MM. Chaudron Giraud and Née, Loiseau, Perrody, Petitjean, Warnon, and Fonteuilles. Bronze medals: MM. Charlot, Cornette, Delforge, Diard, Didier, Bohne, Neveu, and Ullman. Honourable mention: MM. Cloris Baudet and Picq. The jury consisted of MM. Jarriand, Mildé, Journaux, and Armengaud.

Digitized by Google

Cable Repairs.—In our last issue we commented upon the excellent work done by the Eastern Company's ss. "Electra" on the repair of the Direct Spanish Company's cable. The same company's repairing steamer "Volta" during the same week restored communication by the oldest cable which has ever been repaired. The cable was twenty-four years old, and the depth of water 560 fathoms. This fact is somewhat interesting, in that the life of a submarine telegraph cable has been put at ten years. Here, however, we have evidence that at more than double that age a cable will in comparatively deep water stand the rough handling attendant upon a repair.

Obituary.—The death is reported from America of William C. Hicks, at Summit, N.J., on 20th October. Mr. Hicks had been identified with several important patent suits before the United States Courts as an electrical expert, having appeared in behalf of the M'Donough interests against the American Bell Telephone Company, and for the Brush Electric Company against Conduit, representing the United States Electric Lighting Company. He was the son of Rev. J. A. Hicks, of Rutland., Vt., and was born in New York, on 21st July, 1829. He was a graduate of Trinity College, and was the first city engineer of Hartford, having since been connected with various important engineering works.

The Canadian Telegraphs.—Recent advices from Canada state that the construction of the new sections of the Government telegraph line in the north-west territories of Canada was being rapidly proceeded with. The Moose Jaw and Wood Mountain section, 93 miles in length, had just been finished, and arrangements were being made for the immediate construction of the line from Battleford to the place to be selected for the new centre in the Pitt district. The work was to be let in short sections of probably ten miles each, no one but residents along the line being allowed to tender. A line is also, it is said, to be constructed from Edmonton to Victoria, and next year the gap between Pitt and Victoria will be closed.

Electric Lighting at a Bazaar.—On the 11th, 12th, and 13th inst. Mr. Bennett (Messrs. Walker and Olliver's manager) lighted eight military camps, representing the scene of the "Field of the Cloth of Gold," at a bazaar held at the Leeds Town Hall for the benefit of All Hallows Church. The lamps used were of course incandescent, worked by one of the Gramme machines of the firm and a two horse-power simplex gas engine in the basement. The effect, we are informed, was very realistic. By means of Walker and Olliver's patent regulator the variation of the light at the explosion of the engine, which would have been painful, was almost entirely prevented, no countershafting or other mechanical complications being resorted to.

Continental Items.—The Edison lamps in the grand lobby of the Paris opera house are all in place, and a trial which recently took place has more than realised the expectations of the management.—The number of subscribers to the Société Générale des Telephones already exceeds 6,000. On the 12th instant the actual number was 6,001, against 5,464 in the preceding year. In Paris the Société have 3,969 subscribers, served by 170 telephonists. The number of communications exchanged in that city varies between 25,000 and and 30,000 daily. The mail steamer "La Normandie," belonging to the Compagnie Générale Transatlantique, has received a very complete telephone installation, carried out principally with a view to affording rapid communication between the decks, &c., and the engine rooms.

The West Coast of Africa.—The following letter from the secretary of the West African Telegraph Company appeared in a recent issue of the *Standard*:—Observing an interesting letter from your Berlin correspondent upon the subject of colonisation on the West Coast of Africa, and in which special reference is made to the Los Islands—also known as Les Iles aux Anglais—it may be of interest to your readers to learn further, as showing the wide general interest which is being awakened in these parts, that the French Government has subsidised this company to establish a telegraph station at Conakry, in that neighbourhood, on the mainland some ten miles from these islands, so that very shortly they will, by means of our cables, be placed within convenient telegraphic communication with Sierra Leone and Europe. We have no doubt but that this landing has been arranged by means of the treaty existing between the French Government and King Bala Demba, referred to by your correspondent.

The Northern District Telephone Company.—This company are pushing forward the work in their district, which extends from Whitby to Berwick, and having got the exchanges and trunk lines at Newcastle, Sunderland, North and South Shields, Tyne Dock, and Jarrow into good working order, are bringing the principal towns in the south of Durham into the circle. The first lines were opened at Hartlepool and Middlesborough last week, and the trunk line between Sunderland and Hartlepool will shortly be completed. Mr. H. C. Neave, late superintendent of the central switch room of the United Telephone Company, has been appointed inspector of the company's exchange at Middlesborough. It is proposed to utilise the loud-speaking telephone during the present state of excitement caused by the general election, as it is thought that members might deliver their addresses by this means without any of the disadvantages caused by interruptions, probably well meant but slightly embarrassing, in the shape of chair-legs and what Charles Lamb called "the coffins of untimely chickens."

Underground Cables for New York Fire and Police Telegraphs.—Our American namesake says that the 170 circuits of the New York fire department, radiating from headquarters on Mercer-street, are now connected with under ground cables leading out for several blocks in each direction. Connections have also been made with police headquarters by six special subterranean wires, and the Police News Bureau of the City Press Association at 301, Mulberry-street, by three wires to each building. The Waring lead-covered cable has been used for this work, it having been practically tested by the fire department, and found satisfactory after sixteen months' service in different parts of the city. The recent work, which is the most extensive of its character yet undertaken by the departments, was started Saturday evening, October 24, and continued day and night without cessation until finished without interrupting street traffic. Superintendents Smith, of the fire department, and Crowley, of the police department, expressed themselves as greatly pleased with its successful completion.

Telephonic Communication at Sandringham.—A very comprehensive system of telephonic intercommunication has just been completed at Sandringham for His Royal Highness the Prince of Wales, and in the arrangement of which his royal highness was much interested. An entire absence of induction effects was particularly insisted upon, and this has been very successfully accomplished by the use of specially manufactured cables, and which are laid underground in pipes. Eleven of these cables are taken from a switch-board in Sandringham House to various parts of the estate, including the

Digitized by Google

residence of Major-General Sir Dighton Probyn, the equerries' cottage, the agent's house, and the railway station at Wolferton. Messrs. Tasker and Sons have carried out the work, using their usual telephonic combination of Johnson and Bell patents, and the clearness of articulation and the rapidity with which intercommunication can be established are prominent features of the undertaking. At the conclusion of the work his royal highness expressed in gratifying terms to Mr. Johnson his satisfaction at the marked success of the installation.

NEW BOOKS.—Messrs. Sampson Low and Co. have published a work by Mr. W. Barlow, entitled "New Theories of Matter and of Force." From the purely casual glance we have as yet been able to give to the book the new theory seems based upon the hypothesis that "all matter consists of two elementary substances, which, when uncombined and not subjected to extreme pressure, resemble gases in that they are compressible and elastic, and that, as they are freed from pressure, their tenuity becomes practically unlimited. They differ from each other in that when, being under the same initial pressure, the same increment of pressure is applied to both; the one has in all cases a greater increment of contraction than the other, and we accordingly designate them *the more readily compressible ether* and *the less readily compressible ether*, pp. 5-6. Chapters VI.-XVII. inclusive, pp. 63-200 treat of electricity and magnetism; chapter XXXV. deals with electrolysis.—"The Chemical Student's Manual," by H. L. Buckeridge, F.C.S., is published by T. Murby, Ludgate-circus.—"Transit Tables for 1886," by Latimer Clark, F.R.A.S., M.I.C.E., &c. London: E. and F. N. Spon —"Liberty and Socialism," by the Earl of Pembroke. London: Liberty and Property Defence League.

AMERICAN NOTES.—The Daft motor made another trial on the Ninth Avenue line on October 12th, with two cars and 100 passengers, from 14th to 53rd Street and back again.—Electric lighting is to be rapidly extended over the north and west divisions of Chicago. Arrangements have been completed by which central plants will be extended over those districts at once, and the Dorsett conduits will be availed of by a new organisation which promises to do thorough and complete work over large areas of territory.—The senior electrical engineers of the Massachusetts Institute of Technology have formed a society, with the professor at the head, for reading and discussing articles on electricity, as relating to engineering, &c., which appear from time to time in the various technical papers. Each student in turn prepares an abstract, which is read and discussed. Meetings are held each week.—It is proposed to fit up a sleeping car with incandescent lamps, run by the "patented chemical batteries" of the Chemical Electric Light and Power Company, and to light it continuously for three or four weeks without renewing the chemical solution. Arrangements are being made to manufacture the solution for use in every sort of battery now using bichromate of potash.

ON A DIFFERENTIAL-RESISTANCE THERMOMETER.—This consists essentially of a mercurial thermometer having a greatly enlarged bulb, so that the stem may have a diameter of something like a millimetre, and still keep the scale tolerably "open." There runs through the stem a fine platinum wire of 0·08 millimetre in diametre. The lower end may be secured in the bulb, so that it is kept straight in the bore of the stem, and at the lower end a heavier wire is sealed in the glass, so that metallic contact can be made with this wire both at the upper end and through the mercury at the lower. The resistance between these two points evidently depends largely on the length of the platinum wire which is above the mercury in the tube, and this will depend upon the temperature to which it is exposed, the resistance diminishing with rise of temperature by an amount equal to the difference between that of the platinum wire which disappears and that of the mercury which takes its place, less the increase in the resistance of the platinum wire and the mercury due to rise of temperature. Mr. J. C. Mendenall considers this method has an advantage over the use of a simple resistance coil (which the late Sir William Siemens applied in his well-known electrical pyrometers and thermometers), in that the change in resistance accompanying a given change in temperature is much greater, and may in fact be made as great as desired. As a result the telephone may be substituted for the galvanometer in the resistance measurements, or less sensitive galvanometers may be used.—Abstract *Proc.* Inst. C.E.

NEW SCIENCE AND ART SCHOOL.—As a memorial to the late Sir Titus Salt, and in recognition of his benefactions to Saltaire, the Governors of the Salt Schools have decided to build a new science and art school, costing about £6,000. The building will be completely finished by May 15, 1886, on which day will be opened an important exhibition on the lines of the late International Inventions Exhibition. For this purpose the present buildings and a field of six acres will be utilised, the whole being named the "Palace of Delight," in allusion to the ideal institution delineated in Mr. Walter Beasant's "All Sorts and Conditions of Men." Accommodation will be provided for over 10,000 people, and the affair will be the largest of the kind ever seen in the provinces, the probable outlay being over £15,000. With the object of attaining the utmost excellence, space will be allotted only to the most eminent firms in every conceivable branch of industry. Amongst other exhibits will be the South Kensington collection, and the Prince of Wales's Indian collection. The grounds already alluded to will be planted, and illuminated with the electric light, having fountains similar to those at the Inventions Exhibition, illuminated with coloured electric lights. In view of the variable climate, an enormous tent of the American description will be put up in the grounds, capable of holding several thousand people. The arrangement and supervision of the lighting and other electrical work, including the contract of the installation and maintenance of the electric light in the buildings and grounds, have been entrusted to Messrs. Woodhouse and Rawson, of London.

THE NATIONAL TELEPHONE COMPANY.—The fifth annual *conversazione* of the *employés* and friends of the Glasgow district of the above company was held in the St. Andrew's Hall on Friday evening, 13th inst. The assembly was a most successful one, dancing commencing at 8:30. At ten o'clock there was an interval, during which tea was served, after which W. A. Smith, Esq., president-director, took the chair. In his address the chairman drew attention to the extension of and improvements in the company's system throughout Scotland for the past year—by Mr. Bennett in the eastern district, and by their own engineer, Mr. Sinclair, in the west. In those extensions and improvements in the telephone world Glasgow had kept well to the front. Among the improvements he referred to their new switch room in the Royal Exchange Buildings, into which they had introduced the most improved apparatus. Drawing attention to the difficulty that had been experienced in giving to the public the use of the telephone without becoming subscribers, he mentioned that shortly the company would be able to do this by mechanical means, as Mr. Sinclair, along with another gentleman, had invented a very ingenious piece of apparatus whereby this could be done. He said he did not wish to trouble the meeting with statistics, but would just give a few figures to convey an idea of the number of messages that passed over their wires.

Digitized by Google

During the past week over 300,000 messages were sent, making a grand total of 16,000,000 for a year. Songs were tastefully rendered during the evening by young ladies from the switch rooms, and dancing was sustained with unflagging zest until an early hour in the morning.

THE ELECTRIC LIGHT AND THE SUEZ CANAL.—In presence of the continued increase in the traffic through the Suez Canal, even during the present commercial crisis, and to provide for the still greater increase that is anticipated in consequence of the abolition of the pilot dues and the lowering of the tariffs, by which merchandise now reaching Europe from the East and from Australia by the route round the Cape will be able to be sent through the Canal, the company has for the last two years been making experiments with electric lights, with a view to enable vessels to continue their passage through the Canal during the night. These experiments have at length proved so successful that it has been resolved to permit from the 1st of January next all vessels of war and postal steamers provided with the requisite electric lights to navigate by night in that portion of the Canal comprised between Port Said and kilometre fifty-four. Therefore, in almost half that portion of the Canal where ships have to put into sidings to allow other vessels to pass them—in the Bitter Lakes vessels pass each other without stopping—vessels of war and mail boats, that together represent twenty-two per cent. of the total traffic, will be able to continue their passage at all times of the day and night. This will constitute a great saving of time, and M. de Lesseps in his circular expresses the confident hope that the trial will be so successful as to enable him to authorise, within a short delay, night navigation for all descriptions of vessels throughout the whole length of the Canal. The rules and regulations for this night navigation appear very clear. Each vessel is to carry the electric light destined to light up the Canal for twelve hundred metres, or just three-quarters of a mile ahead, and thus to enable the ship to navigate in the Canal with safety.

ELECTRIC LIGHT INSTALLATON AT NEWCASTLE.—The new flour mill of Messrs. J. Davidson and Son in this town is now lighted throughout by electricity on the incandescent system, the entire installation having been carried out by Messrs. Clarke, Chapman, Parsons, and Company, of Gateshead, and consists of about 200 lights, eighteen of these being of 50 candle-power, and the remainder of 20 candle-power. Those in the milling room are placed in opal glass shades hung from the ceiling, and ten are in portable lanterns connected by flexible wires to the main cables, and serve as search lamps for examining the interior of the machines. Two clusters of six 50 candle-power lamps light the warehouse, and a lantern with six 50 candle-power lamps is suspended on the jetty. In the engine room there are fifteen 20 candle-power lamps in handsome venetian shades on polished brass brackets fixed on the pitch-pine dado. The current for these lamps is supplied from one of Messrs. Clarke, Chapman, Parsons, and Co.'s patent electric generators (motor and dynamo combined) of the compound turbine type, fitted with self-acting automatic lubrication and electrical-control governor. This machine, which is capable of supplying current for 250 twenty candle-power lamps, runs at the high speed of 9,000 revolutions per minute, without, the makers allege, the slightest amount of heating. The friction is said to be almost *nil*, it having practically but one moving part. Messrs. Clarke, Chapman, Parsons, and Co. had two of their machines running at the Inventions Exhibition, lighting part of the refreshment rooms of Spiers and Pond. They have also just completed the lighting of Lincoln's-inn Halls, London, and of the large Wilson liner, the ss. "Buffalo," built by Messrs. Palmer's Shipbuilding and Iron Company, Jarrow, and launched a few months ago, besides several other installations.

SEEING BY ELECTRICITY.—On being asked a question as to the possibility of seeing long distances by means of electricity, Prof. Bell replied: "That is the question which is now being asked on all sides, one which I can answer affirmatively. I cannot tell how soon. I only know that the problem is so nearly solved as to encourage investigators to persevere a little longer. I know of at least a half dozen men at work on the subject. The reason why I know is amusing. Several years ago I was experimenting with the problem of the photophone. As you may remember, a ray of light from the sun was the motive power, and selenium the important feature of its construction. When I had solved this problem I deposited a description of my discovery in the Smithsonian Institution without giving any information to the authorities as to what the sealed packet contained. Some persons began to speculate as to the probable nature of the discovery hidden in the packet. Not long afterwards, the London *Nature* stated in a paragraph that I had solved the problem of seeing long distances, and that full particulars of the discovery were contained in a sealed packet deposited in the Smithsonian Institution. Instantly six investigators rushed into print in their respective localities to say that they had already solved the problem, and protesting against my alleged assumption of priority. In New York a Mr. Sawyer wrote claiming the invention. The sealed packet became an object of tender solicitude. I had at that time never given any attention to the subject. Although the indignant six claimed the invention, no one has yet ever seen any one else at long distances, nor has any instrument been exhibited which looks like solving the problem. I think I can say, however, that it will not be long before you can sit in a a room and converse with your friend far away, yet automatically by your side."

RAILWAY CARRIAGE LIGHTING.—In an article upon this subject, *The Times*, after discussing the merits of compressed coal-gas, says that:—"Another system, the merits of which have been discussed, is that of electric lighting. But in the discussion the fact has been lost sight of that what has been done in the way of lighting railway carriages by electricity has been effected in the main at the expense of the patentees or their representatives, without the pockets of railway shareholders being in the least degree affected. Of the schemes which have been brought before railway managers and engineers for lighting trains by electricity, it may be said that their name is legion. But, notwithstanding this, there appear to be only about six trains running at the present moment which are lighted in this way, while some four others have been standing still for such a long time that the suspicion is gaining ground that the carriage superintendent has decided after trial to take off the fittings. The electric lighting of trains would appear to be in pretty much the same condition as the electric lighting of streets and buildings. Sometimes one system is tried and sometimes another, but nothing is definitively adopted and settled. Looking round generally, it appears as though—the Paddington experiment excepted—there is less electric lighting to be seen than there was two years ago." This latter statement is one to which we give an emphatic denial. As regards street lighting in London there is, perhaps, not so much to be seen as when the electric light was brought forward for no other purpose than to forward the views of a whole host of speculators. The light has now to be *paid for*. Therefore, there is less gratuitous display. The electric lighting industry is, however, going ahead. There are but few places where the new illuminant is not to be seen, and

Digitized by Google

no one who has eyes for more than one locality will support the assertion we have quoted.

The Indian Government Telegraphs.—The *Homeward Mail* says that the Indian press is calling for an inquiry into the condition of the Government Telegraph Department, and the cause of the prevailing discontent among its officers. Certain remedial measures, proposed by the Indian Government, appear to be altogether inadequate; and it is to be hoped that no time will be lost in appointing an impartial committee to hold an inquiry, in India, into the grievances of one of the hardest-worked and most harshly treated branches of the public service. The matter has been commented upon from time to time in our columns. It remains now to be seen whether the Government can be forced into the adoption of remedial measures by the pressure of public opinion. The aggrieved officials are by no means destitute of hope. A Defence Committee has been formed for the purpose of bringing their troubles to the notice of Parliament. The principal grievance is of course slowness of promotion; but there are others, though of a minor character, equally in need of redress. "Go where you will," says an indignant correspondent in the columns of an Indian paper, "and you will hear the same story; difficulties in obtaining leave long over-due; frequent and sudden transfers of officers from one end of India to the other without any apparent cause, which invariably occasion great inconvenience, and frequently involve a much greater expenditure than is covered by the travelling allowance granted by Government; the curt and offensive tone of correspondence from some officers; the withholding of local allowances granted to officers of similar rank in other departments; the practice, which has been steadily increasing, of keeping working parties out in camp throughout the hot weather, in spite of an old standing order to the contrary, on works of no real urgency, such as the opening of an unimportant postal telegraph office; juniors doing the work of seniors who draw the emolument—for instance, the junior second grade superintendent holding charge of Bengal, the most important division in India, an appointment which in other services would be held by the senior superintendent of the department; delays in gazetting permanent and temporary promotions."

Sir Frederick Abel on Mining.—At the Society of Arts on Wednesday evening, the opening address of the 132nd Session was delivered by the chairman of the council, Sir Frederick Abel, the subject chosen being that portion of the exhibits at the late Inventions Exhibitions which consisted of the machinery and appliances used in mines. After referring to the terrible dangers incurred by our mining population, Sir Frederick said that considerable interest in particular must be felt in the labours, now fast drawing to a close, of the Royal Commission appointed about six and a half years ago to inquire whether the resources of science could furnish any practical expedients, not then in use, which might be calculated to prevent the occurrence of accidents in mines. Upon the important topic of safety lamps, he pointed out that until within a comparatively recent period only three types of lamp were in extensive use in this country—the original safety lamps, which the miners owed to the genius of Davy and Stephenson; and a lamp not long afterwards devised by Dr. Clanny. These lamps were now useless, and so clearly established was the danger of relying upon them that the commissioners considered it their imperative duty to direct the special attention of the Home Secretary to the matter. At the same time the commissioners had indicated with confidence several lamps which combined a great degree of safety with simplicity of construction and fair illuminating power. The electric light had been looked to as capable of furnishing the kind of lamp required, but the application of it to the purpose had been found difficult, for the fracture of a glow lamp, or the rupture of a conducting wire in a mine, might be as dangerous as an injury to a safety lamp or the lighting a pipe. The recent considerable improvements which had been made in accumulators and in constant primary batteries had led to very important progress towards the attainment of the desired result. Mr. J. Wilson Swan among others had gone patiently to work, and had succeeded in producing a lamp which, with its small storage battery, weighed little more than 8lb., and which furnished a light equal to from two to four times that given by the better forms of safety lamp for a duration of ten or twelve hours. One of these lamps, which are, of course, independent of any outside battery or connecting wire, was exhibited together with some of the older forms of safety lamps.

A Complaint.—Not long ago a deputation of the residents of Gloucester-crescent attended at the Marylebone Police Court to ask for assistance in a matter which they said was of very great importance to them. It was explained that the Great Western Railway Company, for the purpose of lighting their premises and the line between Paddington Station and Westbourne Park, had recently erected in the immediate rear of Gloucester-crescent machinery of so powerful a character that the houses in the neighbourhood were made almost uninhabitable. The machinery had latterly been at work night and day, Sunday included. The tremendous vibration and noise, added to the fumes of smoke, steam, and the dirt caused by the machinery, produced such a nuisance as to be almost unbearable. The noise of the machinery destroyed all quietness during the day time and sleep was interfered with at night. Such an annoyance, it was said, must obviously be a nuisance, and injurious to health, and they asked the magistrate, in the name of the inhabitants of the neighbourhood, some of whom had been in the occupation of their houses for upwards of 20 years, to grant them a summons against the company. Mr. De Rutzen reminded the deputation that a similar application had been made to his colleague, Mr. Cooke. The deputation said that they were aware of that, and that difficulties of a technical kind had arisen, but they were prepared to ask for a summons. Mr. De Rutzen remarked that some time ago he was asked to join with others to put down a similar cause of complaint in a street near Piccadilly, where there was the strongest possible evidence of the existence of a nuisance. Counsel's opinion was taken, and as a result an injunction in Chancery was applied for and granted. The deputation replied that they were anxious for process in this court, as it was most important that as much time as possible should be saved, and besides there was the question of expense. Mr. De Rutzen said that if a summons were granted for a nuisance it would be necessary to call scientific evidence to show that it was injurious to health. The deputation informed the magistrate that the machinery in use was said to be more powerful than that used at the Inventions Exhibition. Mr. De Rutzen said that if the deputation would draw up an information, setting forth the facts on which they relied, he would communicate with Mr. Cooke, who had been already consulted in the matter, and let them know the result. Replying to the magistrate, the deputation said that the company had been communicated with, and although an abatement of the nuisance had been promised, there had not been any sensible lessening of the cause of annoyance.

RETROSPECTIVE NOTES.

The ignorance shown upon many matters relating to the applications of electricity is very great. Nor is this to be regarded as wonderful. The major portion of those interested in the subject have had their attention directed to electrical work under exceptional circumstances. When, however, we can impress upon men the necessity of obtaining trustworthy information on the subject, they will perhaps be led to inquire into what has been done, and what can be done, instead of blindly accepting whatever interested parties may say. The idea of perpetual motion is scorned amongst educated classes—indeed, the ploughboy is almost sufficiently educated to show its impossibility—but highly educated people, and keen men of business, are even now ready to believe anything and everything they are told about electricity. The following Retrospective Notes will show that many developments of to-day were foreshadowed in years gone by. In 1836 the following sentences were published :—

"Since we are on the chapter of coal mines, it seems to us that here is the place to express our astonishment at seeing that one of the most beautiful discoveries of modern science has not been rendered available for the illumination of the galleries. We would speak of the incandescence of charcoal produced in vacuum by means of a voltaic pile. . . . . . There would not be the least fear of danger, since the focus of light would be completely insulated from the external air."

The time of incandescent electric lighting had not in 1836 come. The idea was there, but the dynamo was absent. In 1845, however, the incandescent electric light was actually employed to illuminate a mine. Of course it failed to hold its own, not because of failure in the light, but because of its great cost.

The improvements in incandescent lamps since those days have undoubtedly been great, but they are improvements and nothing more.

In 1848 a combination of permanent magnets with electro-magnets was used for the purpose of increasing the action of the former, the manner of such combination being still further explained as "combining and applying permanent magnets within 'hollow coils' (in connection or not with electro-magnets) to obtain an increase of power at a distance from the main battery."

A striking description of compound winding (used for telegraphic purposes) is given in 1849. Thus:—

"To use weak galvanic currents in electric telegraphs, the electro-magnets carry the insulated coil of the local battery *as well as that of the line wire circuit* (the italics are ours), thus uniting, reducing, or neutralising their efforts."

It will be unnecessary to follow history year by year in connection with this one phase of electrical work; but while we have carefully avoided giving names and references hitherto, we may do so in the following. The *Proceedings* of the Royal Society, Vol. XV., 1866-7, contain, p. 367, the paper by C. W. Siemens, F.R.S. (received February 4th, 1867), "On the Conversion of Dynamical into Electrical Force without the Aid of Permanent Magnetism," followed, p. 369, by the paper of Charles Wheatstone, F.R.S. (received February 14th, 1867), "On the Augmentation of the Power of a Magnet by the Reaction thereon of Currents Induced by the Magnet Itself." These papers of Siemens and Wheatstone led to other papers by Clerk-Maxwell and Ladd, &c., and a letter by C. F. Varley. The letter of the late C. F. Varley, F.R.S., contains this remarkable paragraph :—

"The force expended in the shunt is wasted in heat; *but a secondary wire on the electro-magnet* (the italics are ours), or a copper cylinder would very greatly add to the power by maintaining the magnetism, and not consume uselessly the force now wasted on the shunt."

We will go back again to the year 1850, just to give one more note on this particular subject. A magneto-electric machine was then designed, "with coils both round armature and magnet," though the inventor evidently did not know how near he came to the solution of a great problem.

It will be remembered that one of the early arc lamps introduced from America consisted of carbon plates or carbon discs, the arc running backwards and forwards between the plates. In 1845 a patent describes "circular discs of carbon mounted on axes revolving in bearings . . . the discs are made to revolve with a slow, uniform motion. In order to bring about the desired effect two neighbouring discs connected with opposite poles of the same battery are brought into contact, and, as soon as the points of contact are sufficiently ignited, the discs are to be withdrawn out of contact, when a brilliant and permanent electric light will be evolved."

Some ill-disposed persons who have a prejudice against all things not cockneyfied have gone so far as to say that the keen Yankee, in the time of the electrical boom, hunted out old patents, re-patented their contents, and sold his work for a goodly sum. We have often stated that only a small percentage of patents issued by the Patent Office contained new ideas. Yet we did not imagine that plagiarism in patents was quite so bad as it is till after a long investigation. There can be hardly a doubt, however, but that some American patents are deliberate copies of prior English patents. The subject is not a nice one, and we will leave it.

M. J. Roberts, in 1852, describes a mode of obtaining electric light by passing electricity through a thin piece of graphite enclosed in an exhausted glass globe.

Many readers will understand why these notes are given. A secondary object is to induce those interested in electrical work to be less hasty in believing any invention brought to their notice to be new, and to defer somewhat more than at present to the judgment of technical electrical journals.

THE STEAM ENGINE INDICATOR.—IX.*

BY AMICE.

We may now take, as a simple example of a diagram from a high-pressure non-condensing engine, the one given below, which is from a portable engine by a good maker, but which had been at work several years, without any repairs or adjustment, when the diagram was taken. A thrashing machine was being driven, and the diagram was obtained when the machine was running empty, so that it indicates the power employed simply to work the engine and machine without doing any thrashing.

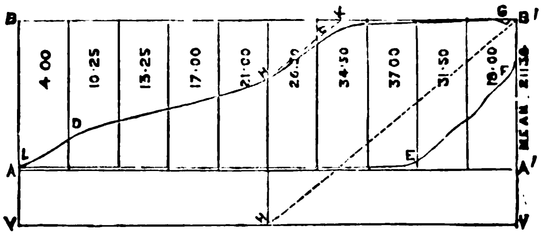

FIG. 35.

The engine had a cylinder 8·5 in diameter and a stroke of 1ft. When the diagram was taken it was running at 115 revolutions per minute, and the boiler pressure was about 47lb. per square inch. The engine was fitted with a common slide valve, with lap sufficient to cut off the steam at about one-third of the stroke, and with a governor and common throttle valve which reduced the initial pressure in the cylinder to that shown on the diagram.

The diameter of the cylinder being 8·5in., the area of the piston was 56·74 square inches. The diagram (Fig. 35) is one of a large number taken during an experimental test of the machine; and it being necessary to take out the indicated power as shown with the machine working under different conditions, the practice of using a constant to simplify the work of calculation, was adopted, and of this we may take an example. The constant for an engine is simply the number which represents the power of the engine per lb. pressure on the piston. In our case, then, it will be

$$\frac{56{\cdot}74 \times 115 \times 2}{33{,}000} = 0{\cdot}3954.$$

* For Art. 8, see *The Electrician*, 13th November, 1885.

Digitized by Google

Our diagram gives us a mean pressure of 21·3lbs. pressure throughout the whole stroke. The indicated horse-power of the engine is then $0·3954 \times 21·3 = 8·42$. This, however, is only as indicated by one end of the cylinder. The diagram from the other end showed how necessary it is to take diagrams from both ends of a cylinder and never to rely upon that from one end only. The adjustment of the slide valve being inaccurate the mean pressure was reduced to 18·3lbs., giving only 7·23 horse-power. The mean indicated horse-power was thus not 8·42 but $8·42 + 7·23 \div 2 = 7·82$.

In small engines the reduction in the effective area of the piston which is made by the piston rod is often—we might say generally—neglected. In larger engines it should be taken into consideration, and we may take this opportunity of an example of its effect. It will of course be very small in so small an engine, but not too small to give some idea of the necessity for making the reduction when the piston rods are large.

In our case the piston rod was 1·5in. diameter; this represents an area of 1·76 square inch, and by this area that of the piston will be reduced at one side, so that the effective area will be reduced by $1·76 \div 2 = 0·88$in., and will equal 56·74 - 88in. = 55 86. Our engine constant will then be $\frac{55·86 \times 115 \times 2}{33,000} = 0·389$. Taking our pressure as the mean of the pressures from the two ends of the cylinder, or 19·8lbs., we have the mean indicated horse-power of the engine $= 0·389 \times 198 = 7·70$, so that the piston rod occupies an area which reduces the power in this small engine by an eighth of a horse-power.

The diagram we have here used is not put forward as an example either of good diagrams or good steam performance, but is taken as illustrating what would be obtained from a very common type of engine, and it shows a good many points to which we must refer hereafter. In our engraving we have marked the atmospheric line A A′, the line of maximum pressure at B′ has been produced to B, so as to form with the vertical lines a parallelogram enclosing the diagram. In tracing the indicator pencil as it produced this diagram, we will commence at L—namely, at the beginning of the return or exhaust-stroke. The diagram is here very near the atmospheric line, the pressure in the cylinder during the exhaust-stroke, or back pressure, being not more than 1lb. per square inch until it nears the last fourth of the stroke and the exhaust port is nearly closed. At E the exhaust port closes, and the vapour left in the cylinder is compressed by the piston as it completes its stroke. The pressure of this compressed exhaust vapour rises to F, or to about 26lb. per square inch. At F the steam port opens and steam is admitted while the piston has yet about one-sixteenth of an inch of its stroke to complete—that is to say, the valve is set with a sixteenth of an inch lead. The sudden admission of the steam drives the indicator pencil up to G above the normal maximum, and the spring in its recoil brings the pencil somewhat below this line. After this a clean line is drawn, the pencil falling gradually as the valve slowly cuts off the steam, the fall in pressure towards C being the result of the wire drawing, as it is termed, which is caused by this slow closing of the port. When a steam port is closed slowly, as it is by an ordinary slide valve without much lap, the pressure in the cylinder falls in consequence of the increase in the velocity of the piston which takes place as the port opening is being reduced to nothing, so that the passage gradually becomes too small to permit the steam to enter the cylinder at a rate sufficient to maintain the pressure behind the piston. A little before the pencil arrives at C steam is cut off and expansion begins, the fall in pressure being rapid at first between C and H, and from this point it is gradual, the slowness of the fall indicating re-evaporation of steam condensed during the previous part of the stroke. At O the exhaust port opens and the pressure falls to near that of the atmosphere at L when the stroke is completed.

Viewed with reference to economy this diagram shows too much compression for the speed of the piston, which is only 230ft. per minute; throttling, slow cut off and wire-drawing, and unnecessarily high pressure at exhaust. Other points to be dealt with by reference to this diagram will be considered hereafter, but before proceeding with these and with diagrams from compound engines we will take a typical condensing engine diagram and a theoretical diagram into consideration.

THE FIRST TRANSMISSION OF POWER BY ELECTRICITY.

At the present time the idea of using two dynamo machines placed at a considerable distance for the transmission of power is so well known as to cause no more surprise than the transmission of the power of a steam engine to the various machines in a factory by means of shafts, belts, or ropes. At the generating station we have a dynamo driven by some prime mover; we have then two insulated wires leading to the point where the power is required, and there we recover part of the energy of the prime mover by means of a second dynamo machine acting as electro-motor. All this is well known, and is now accepted as an established fact, which is as simple and self-evident as the law of gravitation. But there was a time when even this simple and familiar application of electricity was shrouded in mystery, and a *bonâ fide* invention or discovery was necessary to bring it to life.

It is always interesting to go back to the first dawn of a new invention, but it is not always easy to determine whether it was the result of accident, necessity, or the outcome of clear, intelligent foresight on the part of the inventor who was working for a particular purpose. As regards the first transmission of power by electricity, opinions are divided. According to M. Figuier, accident pure and simple, was the cause of the discovery. He relates that at the International Exhibition in Vienna in 1873 the Gramme Company had two machines on view intended for lighting purposes. One of these machines was in motion, and a workman who noticed that some cables were trailing on the ground, and thinking they belonged to the second machine, placed them in its terminals. To the surprise of everybody this second machine, which had been standing, began to turn of its own accord. Then it was discovered that the first machine was working the second.

This story is romantic, but disappointing to a true lover of science, who would prefer to believe that a great discovery was the logical outcome of the working of a powerful intellect, and not the result of accidental meddling on the part of an ignorant workman. But there is another version of the story, told by M. Hippolyte Fontaine to the Société des Ancient Eléves des Ecoles Nationales d'Arts et Métiers a few months ago. M. Fontaine claims to have actually invented or discovered the electrical transmission of power, as will be seen from the following short abstract of his paper read before the abovementioned society :—

"On the 1st of May, 1873, that is on the date fixed four years previously by Imperial decree, the Exhibition in Vienna was formally opened. At that time the machinery hall was yet incomplete, and remained closed to the public until the 3rd of June, when it was also thrown open. I was then engaged with the arrangement of a series of exhibits, shown for the first time in public, which were intended to work together, or separately, as desired. There was a dynamo machine by Gramme for electroplating, giving a current of 400 amperes at 25 volts, a magneto machine, which I intended to work as a motor from a primary battery, or from a Planté accumulator to demonstrate the reversibility of the Gramme dynamo. There were also a steam engine of my invention heated by coke, a domestic motor of the same type heated by gas, a centrifugal pump placed on a large reservoir, and arranged to feed an artificial cascade, and numerous other exhibits. To vary the experiments I proposed to show, I had arranged the pump in such a way that it could be worked either by the Gramme magneto machine or by the steam engines (Fontaine).

"On the 1st of June it was announced that the machinery hall would be formally opened by the Emperor at 10 a.m. on the day after the morrow. Nothing was then in readiness

Digitized by Google

but those who have been in similar situations know how much can be got into order in the space of 48 hours just before the opening of a great exhibition. In every department members of the staff with an army of workmen under their orders were busy clearing away packing cases and decorating the spaces allotted to the different nations. These gentlemen visited all the exhibits in order to determine which of them should be selected for the special notice of the Emperor, so as to detain him as long as possible amongst the exhibitors of their respective countries.

"M. Roullex-Duggage, who superintended the work in the French section, asked me to set in motion all the machinery on my stand, and especially the two Gramme machines. I set about at once, and on the 2nd of June I had the satisfaction of getting the large Gramme dynamo, the two engines (Fontaine), and the centrifugal pump to work; but I failed to get the motor into action from the primary or secondary battery. This was a great disappointment, especially as it prevented my showing the reversibility of the Gramme machine. I was puzzled the whole of the evening and the whole of the night to find a means to accomplish my object, and it was only in the morning of the 3rd of June, a few hours before the visit of the Emperor, that the idea struck me to work the small machine by means of a derived circuit of the large machine. Since I had no leads for that purpose I applied to the representative of Messrs. Manhis, of Lyons, who was kind enough to lend me 250 metres of cable, and when I saw that the magneto machine was not only set in motion, but developed so much power as to throw the water from the pump beyond the reservoir, I added more cable until the flow of water became normal. The total length of cable in circuit was then over two kilometres. This great length gave me the idea that by the employment of two Gramme machines it would be possible to transmit mechanical energy to great distances. I spoke of this idea to various people, and I published it in the *Revue Industrielle* in 1873, and subsequently in my book on the Vienna Exhibition. The publicity thus given to it was so great that I had neither time nor desire to protect my invention by a patent. I must also mention that M. Gramme has told me that he had already worked one dynamo by the other, and I have always held that the honour of my experiment belongs to the Gramme Company."

A PORTABLE ELECTRIC LAMP.

A useful form of lamp, fed by a primary battery, is being manufactured by Messrs. Huon and Collet, of Hatton-garden. A neat wooden case of about 1ft. in height by 6in. square, carries four small bichromate cells and four sets of plates. The incandescent lamp, taking 9 volts and three amperes, gives a continuous light of rather over eight candles for an hour and a half; a very fair result. Referring to our illustrations, P (Fig. 1) is a handle by means of which the movable india rubber cell C, containing the exciting bichromate of potash solution, is brought into contact with the plates of the battery H, which latter are connected with the terminals B B at the top of the apparatus. S is a clamping screw working in a slot cut in the case, and serving to regulate the height to which it is desired to raise the cell C, or, in other words, to diminish the intensity of the light, if such be required, by lessening the plate-surface immersed in the solution. D is also a clamping screw to fix the cell in position for transit or for giving light when the apparatus is set down. Z Z Z Z are screws to which the zinc plates are attached in order to facilitate removal, and L, R, K, and E are of course the lamp, its holder, and reflector; which latter fits into the wooden cylinder K. There is of course nothing novel about this lamp, but it is very cheap and very good. Its chief fault is that it is rather heavy—not excessively so, but greater than is perhaps necessary. However that may be, we think that it will find favour, not only among surgeons, dentists, and others, but with those who require a handy light for the bedside or for moving about the house at night. There is nothing complicated in its construction. The cell, C, is easily taken from the case, a turn of a screw releases the lamp, and when necessary the plates may be removed without trouble. For the use of medical men the apparatus is provided with a small auxiliary lamp (Fig. 2), and a cauterising instrument, with holder and conducting wires (Fig. 3), of too simple a

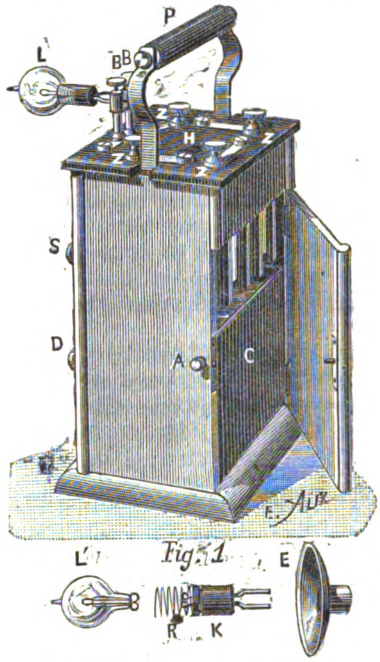

Fig. 1

nature to need explanation. The hand lamps are, we believe, made in three sizes, *i e.*, No. 1, taking 7 volts and 2 amperes; No. 2, taking 8 volts and 2·5 amperes; and No. 3, 9 volts and 3 amperes. Our experiments have been conducted with the latter size, and as a result we are satisfied that its manufacturers have in no way exaggerated their claim to the

Fig. 2

Fig. 3

production of an economical and efficient apparatus, as compared with other lamps of the kind.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the re-assembling of this society for its winter session, on the 12th inst., Major-General Webber, C.B., R.E., read a paper describing the operations of the military telegraphs, of which he was director in Upper Egypt and the Soudan during the campaign of 1884-5. When the expedition was decided upon the first thing he (General Webber) had to see to was the condition and extent of the existing communication south of Cairo. A telegraph had long been erected as far south as Dongola, and even to Khartoum, but it was in bad condition, and for some time past the whole system above the Mudir of Dongola's district had been utterly dismantled. Between Cairo and Assiout, a distance of 229 miles, there were three wires,

Digitized by Google

with a fourth for part of the distance. Only one of these was a through wire, the others being for railway and private messages between these two places. Beyond Assiout there was a single wire to Assouan, 320 miles long, worked by single needle instruments, with numerous intermediate stations. To Wady Halfa, a further distance of 210 miles, a single wire existed, but in a very dilapidated condition, the poles being rotten with the attacks of white ants, and the wires repaired at frequent intervals with dry joints; and from Halfa to Dongola stretched another line 230 miles long, passing over a most desolate, rocky, sand-drifted region, with but few spots intervening where any linesmen could exist to look after the repairs. For the purposes of the expedition, when it arrived the line had to be extended as far as Korti and neighbourhood; but long before then the whole length of permanent line between Cairo and Dongola, 1,000 miles apart, had to be gradually got in working order so as to meet the demands likely to be made upon it as the forces advanced. Faults, of course, were of hourly occurrence, the delay was excessive, even for ordinary traffic, complete breakdown was frequent, batteries had not been replaced for nearly twelve months, and the operators were of a very inferior class. All the wires leading into Cairo passed through the palace; but by the courtesy of the Khedive this element of *espionage* and delay was done away with, so far as the through military telegraph was concerned. Thirty first-rate telegraphists arrived from England, and with their aid the army telegraph construction men gradually got the whole length into tolerable working order. The necessity for pushing on, however, arose in due time; the suspended wire across the cataract at Halfa having broken, it was replaced temporarily by a military ground cable, submerged under the river, an experiment which answered well until a better armoured cable arrived. South of Halfa most of the iron poles of a line of superior construction, which had formerly stretched into the heart of the Soudan, but which had been destroyed, had to be replaced as best could by branches of trees stuck in the ground, and to which the wires were affixed. At some parts of the route the drifting of sand was so great and constant that, as it reached the wires, the custom was to fasten another pole to the lower one, and so raise the wire until this was again in danger of being buried by fresh accumulations of drift. In certain situations this process had been repeated so often that sometimes the wire stood three or four poles higher than its original position. Elsewhere the overflow of the river destroyed the stability of the poles; and where these interfering causes were not at work the inroads of the white ant would soon so enfeeble the erection that the blow of a stick would cause it to crumble to the ground. Superior apparatus arrived from England, thanks to the Post Office authorities, designed to enable duplex working to be introduced; but by that time the traffic had so greatly increased day and night that no opportunity arose for effecting the necessary change. So slow was the means of transit that the cases sent forward by the Post Office in October did not reach Korti till the end of December. Usually the sounder with relay was employed; but sometimes the efficient current was so feeble that a vibrator sounder had to be inserted and the reading done by telephone, which was also used with great advantage for testing purposes. The heliograph was employed only on few occasions, although in General Webber's opinion the atmospheric conditions of Egypt were, in spite of mirage, favourable to heliographic signalling. But the difficulty of camel transport prevented the use of this valuable instrument in many positions where it would have done excellent service, but where instead field signalling had to be resorted to. General Webber paid a high compliment to the signalling corps, and took that opportunity of expressing his strong conviction that the whole body of signallers, both telegraphic and visual, should be placed under one controlling organisation. After furnishing some statistics of the enormous amount of traffic disposed of, the lecturer conveyed his high appreciation of the admirable manner in which the Eastern Telegraph Company had performed their part of the work, and of their liberality in allowing certain messages of painful purport to pass over their wires free; and concluded with a warm eulogy upon the zeal, devotion, and loyalty of all the men under his direction during the campaign.

Several officers, both of the army and navy, offered some brief observations upon General Webber's paper, amongst whom were Colonel HARRISON, who attributed the success of these and similar operations of recent date, first to the excellent organisation, second to the character of the stores, which were the best that money could obtain, and last, though not least, to the hearty co-operation which prevailed between the postal telegraphs of this country and the military service; Colonel BERESFORD, who gave some account of the expedition to Suakim in the direction of Berber, mentioning a circumstance altogether unique in military history, namely, that the telegraph was extended into the very thick of the fight on the occasion of the surprise of General M'Neill's zareba; Captain HAMMILL, senior officer of the Nile transport service at Wady Halfa, gave his testimony to the admirable service rendered by the telegraph to the Nile boat expedition; Mr. OATWAY, who had been in charge of the clearing house of the Soudan telegraphs, furnished detailed particulars of the traffic and revenue; and Prof. FORBES related some of his experiences with the Russian army telegraphs during the Turko-Russian war. A hearty vote of thanks to General Webber concluded the proceedings.

LEGAL.

Wheatley v. Consolidated Electric Light Company.

In the Chancery Division of the High Court of Justice, before Vice-Chancellor Bacon, on the 18th inst., this case came on for hearing.

Mr. MARTEN, Q.C. (with whom was Mr. E. Beaumont), said this was an action to restrain a nuisance caused by the noise and vibration of the defendants' steam engine and dynamo engines. The plaintiffs were Mr. William Wheatley, the tenant, and the Monarch Investment Building Society, the landlords, of an hotel or refreshment place called the Three Compasses, at 66, Cow Cross-street, Smithfield. The defendants occupied 66A in the same street, which was at the rear and on the south side of the plaintiffs' premises. The steam engine was in the basement, the dynamos were on the ground floor, and a party wall separated the defendants' from the plaintiffs' premises. The shaft of the engine was supported by girder bearings fixed into the party wall and thence resulted a noise and vibration which seriously inconvenienced the plaintiff's customers, and had already occasioned him so much injury that he claimed £1,000 as damages. The defendants denied all the plaintiff's statements, and alleged that the machinery had been working from May, 1883, to the present time; but no complaints were made until September, 1884. The plaintiff Wheatley asked for an inquiry as to damages.

The plaintiff was examined, and said the defendants' works adjoined his dining room. He entered the premises on May 19, 1883, and almost immediately felt an annoyance from the shaking of the building and a rumbling noise, which continued from eight o'clock in the morning to eight at night, with one hour's cessation in the middle of the day. Customers had been so much annoyed by the noise that they left the dining room saying they would never come again. The shaking moved the knives and forks on the table, and the empty bottles down below. In the bed room the shaking was felt more than the noise. There had been a falling off in the business to the extent of about £50 to £60 a month. The receipts were nearly £250 a month when witness entered into possession, and they had gradually decreased, with some occasional increases, to £161; but in October of the present year they were £198. Witness attributed the falling off entirely to the noise keeping gentlemen away from the dining room. The position was close to the Meat Market. Witness complained to the defendant company soon after he took possession, and they said they could not be bothered by such complaints, and it would be worse when they got down two or three more dynamos; this answer was given by a man named Taylor. The noise was worse at some times than at others; it had not been quite so bad during the last three months.

Cross-examined by Mr. HEMMING, Q.C.: The directors of the defendant company came on October 2nd to hear what the noise in the dining room was, but they scarcely spoke to witness. There was a falling off in business generally, owing to the universal stagnation. Witness could not say how much of the decrease in his business was a falling off in the dinners. The neighbourhood itself was somewhat noisy. Witness's premises were near the Metropolitan Railway, within 12 or 15 feet; but he did not know there were three trains a minute on the line. There was some vibration from the trains, but nothing like what was caused by the defendants' engines.

The VICE-CHANCELLOR: The trains are not let into his party wall [laughter.]

On Thursday, in further cross-examination, the plaintiff said he first felt the vibration in June, 1883. If his witnesses in their affidavits had said the nuisance commenced in April, 1884, they had made a mistake in the date. He had never heard any complaints that the liquor he kept was bad, and that his customers met with uncivil treatment; and it was a great shame for anything of the kind to be said, for it was not true. Witness's was a yearly tenancy.

Mr. EASON, a surveyor, said he examined the premises of both parties last year, and found five iron girders fixed in the party wall; the whole of the strain of the machinery was upon this wall, and it might be remedied by the building of a separate wall to receive the girders. He suggested this to Mr. Offor, the managing director of the defendant company. Witness testified to the shaking occasioned to the plaintiff's premises, and the constant noise. The Metropolitan Railway caused no annoyance to the plaintiff's premises, where the trains could not be heard. Witness made another inspection in February of this year, and found a number of wooden struts had been erected from the ground floor to the ceiling of the defendants' premises; their effect might have been to diffuse the vibration upon the party wall, but it had not diminished it. The vibration was not so perceptible in the plaintiff's premises as on the former occasion. In June six dynamos and two lathes were at work when witness called, and the noise and vibration were greater than before. The nuisance was so serious to the plaintiff's business that it must involve a reduction of rent to the extent of 15 per cent. The thickness of the party wall was 18in.

Other professional evidence was given to the same effect.

The case was not concluded when the Court rose.

TELEGRAPHY AND THE SOUDAN CAMPAIGN.

The large and influential audience which assembled at the Society of Telegraph-Engineers one evening last week to hear Major-General WEBBER'S account of the Soudan telegraphs, of which he was Director during the recent campaign, were attracted probably more by the national importance of military telegraphy than by any special interest in the particular subject of the paper. The futile expedition for the relief of Khartoum is past and done with, its one redeeming feature likely to dwell in the memory of history being, not the intrepidity of the relieving party, but the stubborn endurance of the party to be relieved. That, however, is no fault of British soldiers or of their officers; and if the gloom of General Gordon's fate still casts its shadow over the glory of his attempted rescue, those men who took part in it—many of whom, besides General Webber himself, were present at Thursday's meeting—might proudly assert that whatever mortals could do under the conditions imposed was done, and that, although they failed, failure was due to no dilatoriness, mismanagement, or lack of heroic devotion on their parts.

The chief lesson of the campaign, indeed, was for the people of this country rather than for Telegraph Engineers, who have little to learn from it, or for military men, who are, or ought to be, agreed as regards its significance. The people of England are too apt to declare at the termination of every war, little or big, that this one is the last, that an era of peace will now most certainly ensue; and the people's representatives are far too ready to listen to such predictions—or rather to echo them, and to act accordingly. For ten or a dozen years past, however, there has been little interval for these foolish fancies to take effect; and if any Englishman survives who, rejecting the experience of his own country, confidently looked forward to a peaceful arbitrament of all future international disputes, and the impossibility of unprovoked hostilities between civilised communities, his credulity must have received a fatal stock at the beginning of this present week. Happily the delusions, bred of selfishness or hypocrisy, which infest the political atmosphere do not appear to have spread to the Military Telegraph Department. One speaker at the meeting we are referring to attributed the success of the Telegraphic Administration in the Soudanese and South African Expeditions in great part to the abundance of telegraph stores of the finest quality that money can buy or science invent. In view of current events, and those other eventualities looming in the not far distant future it is, perhaps, hardly necessary for us to urge with much vehemence the necessity for increasing the reserve stock of telegraph stores and apparatus, and for relaxing no efforts to increase and organise the body of trained telegraphists without whom the costliest appliances are but useless encumbrance.

An illustration of this fact was furnished in the Soudan campaign. It was known that a line of telegraphs existed in more or less perfect condition all along the Nile as far south as Khartoum, some fifteen hundred miles in length. Some of this, of course, had been destroyed; but to Wady Halfa, and partially to Dongola, a thousand miles south ot Cairo, communication was comparatively perfect—that is, perfect in an Egyptian sense. But such as it was it became practically useless directly the demands of a military campaign were made upon it, and chiefly for want of competent native hands to work the instruments, which were of a kind wholly unsuited for heavy traffic and fast working. A contingency of skilled telegraphists, none too large, had to be sent from England; and by good management not only was the line maintained and extended on the heels of the expedition, at all events till the desert track was reached, but a large amount of personal and press traffic was disposed of as well, with, as we all know, extraordinary dispatch. Nothing of this kind would have been possible but for an ample supply of picked men, who, besides being soldiers, were good telegraphists. A purely civilian staff would have been unsuitable for the circumstances, even could they have been enlisted, which is highly improbable. As a fact, it was made up partly of Royal Engineers, and partly of the Reserve Telegraph men belonging to the Post Office Rifle Volunteers.

It is much to the credit of the organisers of this last-named body that it now possesses a considerable force available for emergencies of the kind which arose during the years 1884-5. The Royal Engineers had already been taxed for the expedition in South Africa under Sir Charles Warren; and the later operations in the neighbourhood of Suakim required the equipment of virtually a third corps of telegraphists. We are not sure that the army proper could have responded to these demands, certainly not with such efficiency; for, after all, the only body of men who can be rightly called skilled telegraphists are the Postal Telegraph Volunteers, or such

Digitized by Google

of the Royal Engineers who have been employed in telegraph offices of the Postal Telegraph Service. By wise foresight, and a happy coincidence of views, the postal authorities have almost from the very first acquisition of the telegraphs by the State lent willing help to the military departments, both in men and in the means of training telegraphists for purely warlike purposes. We could, perhaps, have wished this fact to have been more warmly acknowledged in General Webber's discourse, for we share Colonel Harrison's opinion that, next to excellency of equipment, the military telegraph owes its success in recent campaigns to the more than friendly co-operation of the State Telegraphs.

We noted with much satisfaction the uses to which the Telephone had been put during the expedition as a "sounder" in conjunction with vibrators. Where lines are of a very temporary, and, therefore, electrically speaking, of very imperfect description, we long ago predicted that this instrument would be of value for reading by sound where all other apparatus would fail; and we consider that a supply of telephones should form part of every military telegraph equipment. It should also never be without the means of restoring existing lines, which nowadays are met with at most unexpected and out-of-the way spots; and its line of extension should be of the lightest and most temporary kind when speed of erection is imperative. The wire lately erected in Bechuanaland at the rate of six miles a day was afterwards sold as a commercial concern. To follow or precede an invading army the speed of erection should be more nearly six miles an hour. Of course, lines of this description would not satisfy the requirements of the ubiquitous and unconscionable pressmen or the insatiable curiosity of the home newspapers. But the great thing to be done, and the only one worth consideration in the first instance, is to satisfy the requirements of the army and its generals; and for these a rapidly-moving telegraph line is the surest and best. Of course, there are points to which through communication by telegraph is unattainable; signalling by flag or by heliograph may then become almost a necessity. A closer connection, we think, ought to exist than obtains at present between these several systems of telegraphy in the army. But on this and other points relating to military telegraphs we hope shortly to publish some valuable opinions and suggestions by a competent authority on the subject.

HIGH-SPEED ENGINES AT THE INVENTORIES.

In our last impression we published a letter from Mr. P. W. Willans on this the subject of our article of the 6th inst. Mr. Willans' letter makes reference to it necessary at our hands.

First, we must disclaim all intention of withholding in the smallest degree the credit fairly won by certain makers of high-speed engines, and Mr. Willans will be amongst the first to admit the impossibility of referring in such an article to one or even to two engines in particular. We expressly avoided saying that all the high-speed engines had given trouble, and we did give credit for great improvement.

Secondly, Mr. Willans omitted to notice that cushioning has little effect of any kind on the strains to which we in particular referred by example. We dealt with the angular movement of the connecting-rod or its movement in a direction transverse to that of the piston, a direction of movement which throws an alternating transverse stress on the rod measurable by its inertia.

Thirdly, our last paragraph said "the improvements which have been made permit us to indulge in the hope of more." We therefore did not condemn high speed in principle, but the attempts to use high speeds without a proper attention to the proportions of all the parts of an engine intended to run at high speeds, and we gave one example of the heaviness of some of the strains. Incidents at the Exhibition proved the existence of these strains. That similar strains are borne by locomotives is perfectly true, but we may also remark that there are few engines so well proportioned or so thoroughly well made as the locomotives turned out by the leading locomotive engineers.

Moreover, our example was specially taken with a moderate high-speed, namely 250 revolutions per minute, at which, with a stroke of 18in., the connecting rod was forced to acquire an angular velocity of 196ft. per second in 0·06 of a second. If, however, we take the speed at 600 revolutions and a stroke as small as 6in., we get a speed of 157ft. per second impressed on the rod in only 0·025 of a second, which is worse for the rod than the example we had taken, or at least the rod would have to be stronger as against transverse strains. There is nothing impossible in making high-speed engines to run well, but great skill is necessary in designing such an engine, and nothing but good workmanship and material will carry out that design. As to the locomotive, we must also remark that high in character as is the design, workmanship, and material of these engines and their parts, they are never intentionally called upon to run more than about two hours at high speeds.

We are led to reply to Mr. Willans' letter because other readers may have limited their interpretation of our article in the same manner, and for the same reason it is desirable to say a word in reply to Mr. Crompton. It is quite unnecessary that we should say anything concerning engines which were not in the Inventions Exhibition electric lighting shed, and therefore unnecessary to reply to a considerable part of Mr. Crompton's letter. We fully agree with him in his choice of an engine, but we must remind him that in praise of a good engine it is not necessary to pervert the obvious meaning of our article or to attribute to us words which we did not use. We said not one word to lead any one to suppose that we attached any difficulty to the proper balancing or cushioning of an engine. We did not "pronounce insuperable" anything in connection with high-speed engines. We separated the questions relating to reciprocating parts and the employment of a cushion from the one illustration we used, and specifically mentioned this.

Again, we must remark that we did not specifically mention by name those engines which we did not intend should be included in the failures, for very obvious reasons; but we must also add that it would not please any one did we make particular reference to the nature of the failures referred to in general.

CORRESPONDENCE.

THE LAW OF THE DYNAMO MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: As time did not permit of practically any discussion on the paper communicated by Prof. Silvanus Thompson last Saturday to the Physical Society on "The Law of the Electro-Magnet and the Law of the Dynamo Machine," I send the accompanying as my contribution to the discussion.

It consists of a letter written by me from London, on November 15th, 1878, to Prof. Perry, who was then in Japan, and his reply, consisting of a letter and the accompanying paper, dated January 16th, 1878, but which should obviously have been dated January 16th, 1879, Prof. Perry not having, I suppose, grown accustomed to dating with the new year. My letter and his reply are sent you *in original, without any*

alteration or addition whatever having been made since they were written.

Some parts of his paper are obviously intended for me alone, as, for example, when he laughs at my attempting to give the resistances to three places of decimals. I have refrained, however, from drawing my pen through such sentences in order that it may reach you in exactly the same state that it reached me. This paper, although it has never been published, is referred to and its contents briefly indicated in our contribution on Electro-Motors in No. 49 of Vol. XII. of the *Journal* of the Society of Telegraph-Engineers and Electricians, and reprinted in *The Electrician*, Vol. XI., page 330. In the paper, written by Prof. Perry at the commencement of 1879, the formula that has since been called Fröhlich's formula for a series dynamo is worked out, as well as the improvement in this formula (specially referred to by Prof. S. P. Thompson last Saturday) produced by the addition of a constant term for the effect of permanent magnetism. A term for the magnetisation of the iron core of the armature by the current passing round the armature coils was even introduced. That for every speed of a dynamo there is a *critical* value of the total resistance, and that practically no current can be obtained if the total resistance exceeds this value was also arrived at and dwelt on.

The laments made by Prof. Perry in his paper of 1879 on Dynamo-Electric Machines, and, in the letter accompanying it, that he had never seen a dynamo machine, and that no book or paper containing even a picture of a Gramme machine was available, are significant.—Very truly yours,

November 16th, 1885. W. E. AYRTON.

Original letter, written by me, Nov. 15th, 1878.

THE ELECTRIC LIGHT.

November the 15th,
98, Palace-gardens-terrace, W.

"My dear Perry: I want you, if you will, to take up the following question, at your earliest possible convenience (and that is why I send you a separate letter—to impress it on your memory)—what is the equation connecting the electromotive force of a magneto-electric machine with the internal and external resistances in circuit when the current generated is the current employed to magnetise the inducting electromagnets. Take as a special case, if you like, a Gramme machine, the formula must be such that when the external resistance is infinite the E.M.F. is nought, since in that case the current being nought there is no magnetism in the inducing magnets, &c. Schwendler believes it to be

$$E = K\left\{1 - \epsilon^{-\left(\frac{a}{r}\right)^2}\right\}$$

E = E.M.F.
K and a constants
ϵ = 2·71828
r = resistance

for a constant speed of revolution of the bobbins, but on my applying this formula to a number of experiments, I do not get agreement. I had to determine the constants by a graphical method of intersecting curves, since I found, on expanding in series, that even the fourth and higher powers could not be neglected, and this made an algebraical determination almost impossible.

I have gone through the complete work, both when "r" is the external resistance only, as well as when "r" was the total resistance in circuit—that is, included the resistance of the machine. I should have mentioned that in these experiments the light was not in circuit, but only a resistance coil of enormously thick wire, the resistance of which could be varied, so that there is no doubt about the accuracy of the measurements of resistance. The E.M.F. was calculated by multiplying the resistance by the current in absolute measure. I append some of the numbers to give you an idea of the experiments. It would be well, however, if you could determine a formula from general reasoning, and not merely a formula which satisfies the particular numbers obtained experimentally, since there may possibly be leakage when the external resistance is small, or when the E.M.F. is great; or as Sabine (partner of Sir Samuel Canning), to whom I have spoken on the subject, suggests there may be some inductive effect set up in each bobbin at the moment it is separated from the collecting brush. If you do not remember how these machines are made you will find accounts of all the different machines in the *Telegraph Journal* or in the *Engineer* or *Engineering*. *Remember no proper formula has yet been published, and it is much wanted.*—Yours sincerely, W. E. AYRTON.

Prof. John Perry.

P.S. It is possible it may be too late to post the newspaper (*Electrician*) by this post, but that will not in any way prevent your attacking the problem.

The Electrician I refer to is for October 26th, 1878, No. 23.

External resistance in Siemens' Units.	Internal resistance in Siemens' Units, that is, resistance of machine.	Sum R·	Current in Webers	E.M.F. in volts C × R.
5·195	0·645	5·850	6·22	34·70
5·095	0·645	5·740	6·85	37·50
4·620	0·675	5·295	9·342	47·17
4·345	0·635	4·980	10·94	51·96
3·930	0·670	4·600	13·32	58·43
3·555	0·645	4·200	15·54	62·25
3·205	0·660	3·865	17·71	65·28
2·840	0·655	3·495	20·01	66·70
2·490	0·635	3·125	22·60	67·35
2·125	0·635	2·760	25·72	67·70

The resistance of the machine varies slightly by heating, ∴ the numbers in column 2 are not quite all equal. I have allowed in calculating the last column for the fact that the resistances were measured in S. U., and not in ohms.

The above are obtained with magneto-electric machine A Siemens.

The following with magneto-electric machine C Gramme's.
Mean internal or machine resistance 1·16 S.

External resistance. S. U.	E.M.F. in volts for mean speed 867·5 revolutions per minute.

5·085	66·39
4·345	68·89
3·535	72·08
1·320	73·97"

Tamiēke Asabu, Tokio, Japan,
16th January, 1878.

"Dear Ayrton: With this you will, I hope, get my ideas on magneto-electric machines. But it is awful to have to write on such a subject, not having an example to look at.—Yours truly, JOHN PERRY."

DYNAMO ELECTRIC MACHINES.

Our object is to get a rational formula connecting the electromotive force and resistance of dynamo-electric machines. We shall suppose that at all speeds and with all resistances with which we have to deal, the internal resistance of the machine is constant; that is, that there are no sparks at the brushes.

We shall also suppose that when the bobbin is rotating uniformly the resultant electro-magnetic force, and the directions of the lines of force at any point near the bobbin remain constant. It is quite evident that this is the condition which holds with more and more truth as we make the separate coils of our rotating bobbins greater and greater in number, and as our resulting current is more and more constant. Evidently this means perfect symmetry of the bobbin about any place through its axis.

Our theory depends on the following facts; first, the shape of the field of force about an electro-magnet and in the neighbourhood of pieces of soft iron under its influence is independent of the strength of the current; second, the

Digitized by Google

resultant force at every point in the field about an electro-magnet is $\frac{aC}{b+C}$, where a and b are constants and C is the current.

The first fact we have roughly proved by means of iron filings on sheets of paper. We cannot imagine that it is strictly true for all currents and all magnets, but we think it true enough within the moderate ranges in which our calculations are to be employed. We are now finding accurately what changes do occur in the shape of the lines of force about an electro-magnet when the current is altered. And here let us remark that this iron-filing method, although sufficiently accurate when large electro-magnets are in question, cannot be regarded as even giving approximately correct results when employed to give shape of a weak field. We have known some experimenters use a thick coating of iron filings in getting the field about a wire conveying a weak current of electricity. We would ask them if the force at a point in the field about a magnet is not somewhat influenced by a string of nails leading to the pole of the magnet, and if such a string of nails does not materially influence the shape of all the rest of the field.

For the second fact, until our own experiments are completed, we must depend upon the experiments of Waltenhofen and others described in Wiedemann's "Galvanismus," and from these it may be shown that

$$m = \frac{aC}{b+C} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where m is the magnetic moment, C the current, a and b constants. This is only an empirical formula, but its suitability strikes one at once. Thus we see that it satisfies the known conditions for weak currents, since with weak currents it is known that the magnetisation is proportional to the current. Also as the current gets greater and greater, the magnetisation approaches a limit, the point of saturation.

Thus, taking at random some of Waltenhofen's results given in the following table, where m is the magnetic moment and C is the magnetising current observed :—

m.	C.	Calculated. m.
1·37	2	1·87
2·79	4	2·74
3·31	6	3·24
3·66	8	3·56
3·76	10	3·78
4·11	15	4·14

The third column is seen to be sufficiently near the observed values. The third column is calculated from

$$m = \frac{5{\cdot}077\,C}{3{\cdot}408 + C},$$

whose constants we have determined by method of least squares.

It will be found that in this and every other case the empirical formula

$$m = \frac{aC}{b+C}$$

is more satisfactory than the formula

$$m \propto \tan^{-1} aC$$

given by the experimenters. (This is not the only reason why we have chosen this formula. Our best reason is that the trigonometrical formula, when applied in the following way, leads to a result which is rather difficult of application, namely, that in a dynamo electric machine if E is E.M.F. in circuit and C is current, then

$$E = a \tan^{-1} (b \tan^{-1} cC) + d \tan^{-1} eC$$

Now, as our empirical formula is as good or rather better than the trigonometrical one we use it.)

Given a coil of wire surrounding an electro-magnet, if we know the current in the coil we know the field of force which produces magnetisation. If the iron were spherical or ellipsoidal we could determine accurately the magnetisation and the field of force due to the magnetising current and to the magnetisation, on the assumption that the coefficient of induction is constant. But it is well known that this is only true when the current is comparatively weak; whereas, more towards the point of saturation, the only relation which we can take between the magnetising force X and the magnetisation A at any point in a mass of soft iron is

not $$A = KX$$

but $$A = M - \frac{N}{X^2}.$$

It will be at once seen that although X satisfies the characteristic equation $\nabla^2 X = 0$, A does not satisfy it, and we see, therefore, that even to a sphere we cannot apply the results of Poisson's theory. According to this theory, if we alter the current which produces magnetisation in a sphere of soft iron, we alter the resultant force at any point in the same ratio, but the shape of the lines of force remains unaltered ; but this is not the case for a soft iron core of any other shape, nor is it true for a spherical core if A is not proportional to X.

Our two assumptions are therefore based on a limited number of experiments, and we have been surprised to find that of available information on the subject there is so very little.

When the bobbin is rotating uniformly, since we have assumed its perfect symmetry, the direction of the lines of force at any fixed point is, by our first assumption independent of the current, being simply a function of the position of the point, and the part of the resultant force at the point due to the electro-magnet alone is

$$\frac{aC}{b+C}.$$

Now, it is this force which, with the currents circulating in the bobbin, magnetises the core of the rotating part, and according to the same law the total resultant force at any fixed point ought to be expressed in the form

$$e + cC + \frac{aC}{b+C} + \frac{a''C}{b''+C}$$

where e, c, a, b, a'', b'' are constants, for it evidently consists of the following terms :—

1° A small term e due to permanent magnetism of magnet, or core, or the earth, or &c.

2° A small term cC due to current in the wire. (Remember that C is constant if the separate coils of the bobbin are infinite in number.)

3° A term $\frac{aC}{b+C}$ due to mag. of electro-magnet.

4° A term $\dfrac{A\dfrac{a'C}{b'+C}}{B+\dfrac{a'C}{b'+C}}$ or $\frac{a''C}{b''+C}$ due to magnetiz. of core,

which is itself produced by magnetisation of the outer magnet. (Easy to show this term very nearly prop. to C.)

It is evident also that any other terms will be of this shape $\frac{aC}{b+C}$, produced by magnetisation of bobbin's core by the current round bobbin, &c.

The electromotive force in an *element* of wire of the bobbin is therefore proportional to

$$n\left(e + cC + \frac{aC}{b+C} + \frac{a''C}{b''+C}\right)f$$

when n is number of revolutions per minute and f is a function of the *position* of the element, which is the same for all elements reaching that position. (This proportionately to n is only true if iron is truly *soft.*)

Hence, the total E.M.F. of the circuit, being the sum of all such terms as this, may be put (leave out term n since it is constant in the problem proposed to J. P. by W. E. A.)

$$E = p + qC + \Sigma \frac{aC}{b+C}$$

where p, q, a, b, &c., are constants. Now since, until iron is

Digitized by Google

getting saturated, C is less than b in all the terms, we may use the expansion

$$\frac{aC}{b+C} = a\left(\frac{C}{b} - \frac{C^2}{b^2} + \frac{C^3}{b^3} - \&c.\right).$$

So that so long as C is less than the various values of b we may use only a few terms of the right hand side of the following equation.

$$E = a' + b'C - c'C^2 + d'C^3 - e'C^4 + \&c.,$$

for we see that c', d', e' are in descending order of magnitude. Now, we are prepared to show that for the known dynamo-electric machines this is the case. If quite true, they mean that saturation is not approached, because this would mean that $C > b$.

In dynamo electric machines, when C is not too small, the constant term a' is insignificant (it is due to permanent magnetic field). But in neglecting it, as we shall do, we must not use our subsequent formulæ for currents which are exceedingly small.

Since, if r is total resistance of circuit $E = Cr$

$$r = \frac{a'}{C} + b' - c'C + d'C^2 - \&c. \quad . \quad . \quad . \quad (I)$$

Although in dynamo-electric machine the first term is insignificant, its importance is shown when we assume that r gets greater and greater, and $\therefore$ C smaller and smaller. We would infer from the formulæ that when the current gets very weak, if there is no permanent magnetic field due to earth, or other perm. magnet, then, since $E = b'C$ and $E = rC$, cannot both be true at same time unless $b' = r$, the current must diminish to zero or else increase.

I should think that if r is greater than b' the current would diminish to zero, the rotation of bobbin being maintained constant, but if r is less than b' then the current will continually increase until some point is reached for which

$$E = b'C + c'C^2 + \&c.$$

In fact, therefore, it would seem that if there is no permanent magnetic field, there is a limiting value for r beyond which we cannot get a current.

To illustrate this part of subject, suppose we use *no* soft iron, merely coils of wire in the whole apparatus. Then the strength of field due to C is known to be proportional to C, and if we have also a permanent field*

$$E = n(aC + b) = A + BC \text{ say,}$$

but $\quad E = rC$, if r is total resistance of circuit,

$$\therefore Cr = A + BC$$

(1) . . $r = \frac{A}{C} + B$ (C very small implies r very great.)

(2) . . $E = \frac{Ar}{r - B}$

Now, what is the meaning of $r = B$ in (2)? We cannot say, except that it might, we expect, be shown in some way to be impossible. A very interesting experiment might be made with a dynamo electric machine using *no* soft iron and having the internal resistance very small, reduce the total resistance more and more. In the absence of experiment we can only say that, if the constant term due to perm. mag. be supposed $= 0$, then there seems to be only one resistance which will enable the equation to be satisfied for a given number of revolutions. That is, if speed is constant, if $r > B$, then current will diminish to zero. If $r < B$, then current will increase to infinity (!!). Possibly the results of experiment would enable us to understand this better, but I do think that some startling result would be derived.

In the absence of such experiments, and since also we have no experiments to appeal to with regard to the gen. formula for magneto electric machines ( ) when the currents are very weak, we must ask that this formula (which is merely a reduction of $E = AC + \Sigma\frac{aC}{b+C}$) where the constant term is left out, be only applied to the usual cases of magneto electric machines, the resistance not being very great. And the modified formula

$$E = b'C - c'C^2 + d'C^3$$

be only applied to cases where the current is neither too great nor too small. We have no doubt, however, that observation will confirm the general formula (I).

Thus to take the only observations at present available, namely, some observations . . . . . . Sent by Ayrton to Perry.

Ayrton to make other observations and try if they fit the formula, also to try if, when resistance is *very* great, our theory, given above, is right, then he can modify the above statements.

SIEMENS' MACHINE A.

3·535	72·08
1·320	73·97

Mean internal resistance 1·16 S.U.

The observations from Gramme's machine do not satisfy the linear law $r = a - bC$, as may be seen by plotting on squared paper (plot both for Siemens and Gramme to show the difference). But I am sure that Gramme would satisfy

$$r = a - bC + dC^2$$

I have not enough observations to try this.

We have plotted the observed values of r and c for Siemens' machine, the values of r and c being co-ordinates of points, and we find that these points all lie nearly in a straight line (perfectly straight for the first six values of C), and, therefore, for such currents and resistances as the observations give the higher terms disappear. So that the general formula

$$E = A + BC + \Sigma\frac{aC}{b+C}$$

becomes $\quad E = aC - bC^2$

since $\quad r = a - bC.$

Putting this in the shape $\frac{r}{a} + \frac{b}{a}C = 1,$

or $\quad a'r + b'C = 1,$

and using methods of least squares, that is getting a' and b' from the two equations

$$\left|\begin{array}{l} a'\Sigma r^2 + b'\Sigma rC = \Sigma r \\ a'\Sigma rC + b'\Sigma C^2 = \Sigma C \end{array}\right|$$

we find as our result that

$$r = 6·798 - 0·1622\,C.$$

* Truly, since we must imagine no change in shape of lines of force, we must imagine, 1st, that a very thin bar of soft iron placed in the outer coil and magnetised with a weak current. Now, imagine that for all future time this soft iron becomes *hard steel*, not changing its magnetisation. This is what we must suppose producing the above constant term.

Digitized by Google

Applying this to the values of C given in original table we get the following values of r:—

Observed. r	Calculated. r	Difference.
5·850	5·789	−0·061
5·740	5·687	− ·053
5·295	5·282	− ·013
4·980	5·023	+0·043
4·600	4·637	+ ·037
4·200	4·277	+ ·077
3·865	3·925	+ ·060
3·495	3·553	+ ·058
3·125	3·132	+ ·007
2·760	2·625	− ·135

(I am sure these differences are well within limits of your measurement. Three places of decimals, indeed. I don't believe it! Coil was heating?)

(In getting out the above formula, &c., Perry worked a week doing "*sums*," as Milne puts it. Such columns of least squares. Bottomley's tables give fearful results. Such reams of paper have been used!)

Now, what I see, judging from the very meagre information at hand (I cannot get a description of Gramme's machine. Shida has three volumes of *Telegraphic Journal* in the country; two volumes of *Engineering* and *Engineer*, which may possibly speak of Gramme, are out of the library. I have only Brittle's paper of Institute of Civil Engineers, and short sketches of a few magneto-electric machines, but not one of Gramme), is this, that Siemens' machine is nothing like so good as Gramme's. Gramme has his iron more saturated, ∴ in a more efficient state. He can use ever so much more speed, and therefore he can make it smaller.

Since (Siemens) the observations of r and C are nearly in a straight line on squared paper, but *not quite*, I assumed

$$E = aC + bC^2 + dC^3$$

or

$$r = a + bC + dC^2$$

and tried to find a, b, d by method of least squares. But the work is awfully long, and after wasting two nights at it, and being wrong twice, I leave it to you to do.

You can make lots of observations on lots of machines, and argue on them on the above lines.

Always choose the equation

$$r = a - bC + dC^2 \quad . \; . \; . \; . \; . \; . \; . \; . \quad (1)$$

or

$$r = a - bC \quad . \; . \; . \; . \; . \; . \; . \; . \; . \; . \quad (2)$$

or

$$r = \frac{a}{C} + b + \Sigma \frac{e}{f + C} \quad . \; . \; . \; . \; . \; . \quad (3)$$

If (2) suffices (tested by squared paper) then there is little *saturation* in the machine. If (1) suffices there is more saturation, but still not very much. If neither suffices then we need to assume $r = \Sigma \frac{a}{b+c}$, or (3).

With an
sheets of paper and iron filings the true

in a diametral plane for currents of all
possible get at a number of points the st
field by a small vibrating magnet or to
with the horse-shoe magnet.

Compare results with sphere with the results of Poisson's theory, and consult Clerk Maxwell's book on current function ϕ, &c., &c. You will find here matter for a very good paper, and the experiments will not be difficult. You may also try an ellipsoid of soft iron, but calculation is more difficult.

Is it true that the field remains nearly constant in shape? Does the magnetic moment follow the law $m = \frac{aC}{b + C}$, where C is current, a and b constants.

You ought to try above experiments with soft iron, then use same coils on equal spheres of steel of various hardnesses, &c., &c. This is really the scientific way of proceeding in experiments on magnetism. Use *Spheres*. Your coils you may make in the shape of two rigid hemispherical shells, so that you may remove one sphere and place on another.

Especially try up to SATURATION *points.*

* [The manuscript here is torn, and a figure of a small magnet has been omitted.—ED.]

A PHENOMENON OF CURRENT INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The correspondence of Mr. E. A. Williams and Mr. J. T. Sprague on this subject recalls to mind some investigations on this subject by Mr. Rankin Kennedy, of Glasgow, which I, as a student, had an opportunity of witnessing.

Mr. Kennedy took a large induction coil, passed an alternating current through the primary wire of this from a dynamo; the same current also passed through and fully lighted up about a dozen incandescent lamps in parallel, so that any variation in the strength of the current was visible and perfectly apparent on the brilliancy of the lamps.

The core of the coil, which had been withdrawn before switching on the current, was first gradually entered into the coil, and as it entered the current became less and less in the primary circuit, which effect was nicely observed in the decrease of the lights from the lamps, they finally becoming quite a dull red. During this experiment the secondary circuit was not closed.

The first experiment showed clearly that the effect of the iron core being introduced into the coil was to diminish the primary current very considerably.

In the next experiment the core was withdrawn when current rose to its former strength as seen on the lamps, and now a lamp was connected to the secondary circuit of the coil, and although the large current was alternating in the primary this lamp in the secondary was barely a visible red light. On introducing the core into the coil now, the primary current fell off again, but not so much as before, while at the same time the lamp in the secondary became brighter, showing that while the introduction of the iron core reduced the primary current it increased the secondary current.

In the next experiment the one lamp in the secondary circuit was switched out while the core was in the coil (and the lamps in the primary circuit consequently very dull). The consequence of switching out this lamp in the secondary circuit was most remarkable, the lamps in the primary circuit became duller still; on switching on lamps one by one in parallel into the secondary circuit the lamps in the primary became brighter and brighter, showing that the primary current increased as the secondary increased, and *vice versâ*; in fact, it was shown that by short-circuiting the secondary circuit the current in the primary rose from 8 to a value of 12 amperes.

It was shown that as the resistance of the secondary circuit decreased the current in the primary increased up to a certain point, at which the primary current ceased to rise, and the E.M.F. in the secondary circuit commenced to fall, and continued to fall until completely short-circuited. This account of Mr. Kennedy's class experiments may throw some light on the matter in discussion, and may be of interest to many as very instructive and beautiful experiments. They were made about three years ago, and it was expected that a full account of the investigations would have been published by the author of them; this has not yet been done, and hence I venture to contribute this from my notes.—Yours, &c.,

Glasgow, 7th Nov., 1885. AN ELECTRICAL STUDENT.

THE VALVE TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you kindly grant me a little space in which to correct a few inaccuracies which have crept into your description of the instrument which is described on page 9 of your current issue as my invention.

The instrument which you figure is not the invention of myself alone; it was devised jointly by Mr. Philip Jolin, of

Digitized by Google

Bristol, and myself, under my patent of 1882, and it is fully described in our joint specification for valve telephones, in which specification, however, many forms of instrument are described beside the particular one figured in your cut. In that form of instrument there is a mouthpiece or funnel affixed to the lower end of an open tube, which is supported in a substantial bracket, and leads the speaker's voice direct to electric mechanism at the top. This mechanism is extremely simple, and in the form of instrument in question consists only of a ball resting on three points let into the top of the tube. The ball shown in your engraving consists of an alloy or composition of which the essential ingredients are copper and selenium, or similar materials, and, as your readers will observe in your cut, the lower side of the ball, which makes contact with the three pins, is polished bright. A light wire or stay is carried through the ball and is formed into a loop at the top. The majority of our instruments in use are of this type; but, as our specifications show, other forms of valve beside the ball can be similarly used to receive *the direct impact* of the speaker's voice, and we have laid no formal claim in our specifications to the particular composition or material which we employ in any of these instruments, seeing that almost any of the substances of which a good microphone can be made can be employed in one or other of our various forms. We have tried coke and carbon, but find the articulation less crisp than with our composition.

With the particular forms used by Mr. Irish subsequently to our invention we have nothing to do, and are willing to give him every credit for the undoubted ingenuity which he possesses; but we must kindly be permitted to doubt whether he or any other person has invented a simpler arrangement than ours, or one which possesses a clearer articulation.

You further say that it is open to question whether it is really the case that we do not use a diaphragm. Will you kindly allow me to remove that doubt; we do not. Our tube is open from end to end, so that the speaker's voice goes direct up the tube to the electric valve at the top.—Yours, &c.,

November 14th, 1885. SILVANUS P. THOMPSON.

HIGH-SPEED ENGINES AT THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have read with much interest your leading article on the subject of high-speed engines, and Mr. Willans' reply thereto in your last issue. We agree with Mr. Willans that your article contains a number of statements which are not borne out by actual practice in the use of these high-speed engines. Your remarks seem to be based on the indifferent performance of those high-speed engines which were tested at the Inventions Exhibition, many of them for the first time, and certainly do not apply to the engines made by Mr. Willans himself, and probably also to those of more than one other maker. Anyone reading your article would be led to believe that the questions of balancing and cushioning high-speed engines, by which we mean those running at speeds varying from 300 to 600 revs. per min. are so great as to be practically insuperable. How, then, sir, do you account for the fact that the whole of the electric lighting machinery of the ships in Her Majesty's navy are driven by such high-speed engines running at speeds varying from 380 to 450 revs. per min., and that Her Majesty's engineers are in every way satisfied with them?

As a matter of fact the difficulties which you pronounce insuperable have been surmounted by Mr. Willans himself, as well as by others. We ourselves feel the utmost confidence in supplying to our customers dynamo machines driven directly by Willans' engines at speeds not exceeding 550 revs. We mention this limit, because we think it is only fair that it should here be publicly stated that one of our dynamos, driven by a Willans' engine at this speed of 550 revs., supplied the current for lighting Old London during the whole of the Exhibition, that it never stopped or was eased down for one moment, that it was never necessary to use the spare set, and that the engine and dynamo both are absolutely as good as the day they left our respective workshops, and that we are certain that this result has not been excelled, if equalled, by any set of high-speed dynamos coupled to low-speed engines and worked for an equally long period.

We hope to have the pleasure of laying before you the results of a series of a trials made with large dynamos driven direct by Mr. Willans' latest form of compound engine, which have yielded results, as far as we are aware, the most economical yet attained in the return of useful electrical energy at the terminals of the dynamo as compared with the coal used in the boiler.—Yours, &c, R. E. CROMPTON AND CO.

ON THE AMOUNT OF LIGHT OBTAINED BY INCANDESCENT CARBON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: If an electric current is passed through an incandescent lamp the effect of the curent will manifest itself by the heat generated in the carbon.

As long as the temperature is low no visible rays are emitted, but with the gradual rise of temperature luminous rays are given out, which soon increase in intensity. The total amount of energy which is then expended by the carbon may be considered as consisting of both heat and light radiations.

As the amount of light obtained from the incandescent carbon increases with the temperature of the same, it appears as if a certain fixed relation might exist between the light and the total amount of energy radiated from the carbon.

Now, the incandescent lamp offers to us one of the means of investigating this question, because the total amount of radiated energy must be equal to the electrical work consumed in the lamp, provided that no losses of electric energy occur.

If, then, we measure the amount of light obtained from the incandescent carbon, from the first stages up to the highest temperatures, and at the same time note the corresponding value of the current, as well as the difference of potential at the terminals of the lamp, the product of the two last, now generally called the number of watts, will give us the energy corresponding to the light emitted.

By comparing a large number of measurements made on different lamps in reference to this question, I find that the following relation appears approximately correct:—

The amount of light obtained from an incandescent lamp increases with the third power of the number of watts required.

Or, if we express this relation in a more general way, in which it seems more likely to be true, we may say:—

The amount of light obtained from carbon at different stages of incandescence increases as the third power of the total amount of energy radiated from the carbon.

We may express this relation in its first form by the following formula:—

If λ is the amount of light emitted, generally measured in standard candles,

V A the number of watts required for producing the light λ,

then $\frac{(V\,A)^3}{\lambda} = K$, in which K has a constant value peculiar to every lamp.

Before proceeding any further, it may be as well to notice one useful practical application of this formula. It is often desirable to know at what candle-power a certain incandescent lamp will work with a specified expenditure of energy, say with n watts per candle; in this case we have $V\,A = n\,\lambda$, and by substituting this value of V A in the equation given above we get at the candle-power required, $\lambda = \sqrt{\frac{K}{n^3}}$. The constant K can be determined by making one single measurement at any arbitrary candle-power. This rule of course only applies within those limits within which the general formula is correct, as will be explained later on.

The formula given above may be put into a different shape by expressing the energy in terms of the current (C) and resistance (R); we then have $\frac{(C^2\,R)^3}{\lambda} = K$.

Digitized by Google

Now, within certain limits the resistance of a lamp changes very slightly, and may therefore be considered as constant. It then appears, that within these limits the amount of light varies as the sixth power of the current, a fact which has been observed before by Mr. Preece and by Mr. Kittler.

The value of K, which I have hitherto considered as constant, is only so up to a certain state of incandescence, and is then subject to variations, which seem to depend on the style of the lamp.

At first the value of K is slightly higher, but soon reaches a minimum ; it then remains practically constant up to a candle-power which is largely in excess of the normal candle-power. The slight decrease at low candle-power does not always occur, and may be due to uncertainties in the measurement of light, when the carbon is of a reddish colour. But the growing increase in the values of K at the highest state of incandescence must be due to other causes. We must either suppose that the relation between energy and light at the highest state of incandescence of carbon has a form differing from the one which I have stated above, or that losses of electric energy occur inside of the lamp. In this last case the measured value of V A would be in excess of the energy which is radiated from the carbon, thereby producing an increase in the value of K.

From observations on incandescent lamps I am inclined to think that such losses of electric energy actually occur, and that they grow with the increase of the temperature of the carbon and with the difference of potential between the two terminals of the lamp being at the same time dependent on the state of the vacuum. The experiments made by Mr. Preece on a model suggested by Mr. Edison quite confirm this view. I have therefore preferred to state the apparent relation between light and radiated energy in its more general form, irrespective of the incandescent lamp.

Although the measurements which are in my possession have induced me to publish these remarks, it would be interesting to see the same verified or corrected by the results which others may have obtained by accurate measurements.

And, furthermore, it appears desirable that the relation between the radiated energy and the light emitted by incandescent carbon at different temperatures should be observed, independent of the electrical energy consumed.—Yours, &c.,

ALEXANDER BERNSTEIN.

HEDGES' AUTOMATIC AND FUSIBLE CUT-OUTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the supplement of *The Electrician* of November the 6th you were good enough to give a description of some of Mr.

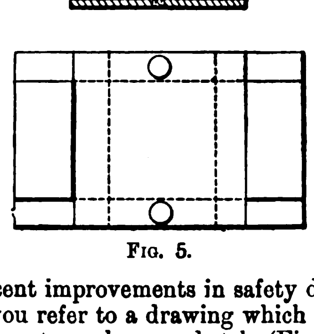

FIG. 5.

Hedges' most recent improvements in safety devices which we exhibited. As you refer to a drawing which does not appear, we have the honour to enclose a sketch (Fig. 5) of the new mica foils described in your article. These fuses can be relied on to melt within 10 per cent. of the current marked thereon ; thus a fuse marked 100 amperes will be melted with a current between 95 and 105. Carrying out a suggestion which appeared in your columns some time ago, we propose making them still more sensitive, so that by inserting a Hedges cut-out in the circuit of an amperemeter the instrument can be checked by noting the current registered when the fuse is melted. As accurately cut foil melts with a maximum deviation of 2 per cent., it will be possible to keep all instruments within this limit of error without the trouble of calibrating.—Yours, &c.,

J. BURGIN, Secretary,
Globe Electrical and Engineering Company.

20, Dartmouth-street, Westminster, S.W.

THEORY AND PRACTICE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The justly-appreciative article on Mr. Williams's "Manual of the Telegraph" which appears in *The Electrician* contains the remark that "few men can be found to attempt the practical work," and refers to the enormous disproportion in the number of theoretical and practical men, although, as the writer observes, it frequently happens that "theory says so and so will happen if so and so be done. Practice says so and so cannot be done, and therefore the theoretical so and so cannot happen." In my experience I have even had this position reversed, theory asserting that so and so could not be done, practice proving that it could be done. I never forget my personal experiences of the Postal Telegraph Department, and when on one occasion Sir William Thomson and Prof. Fleeming Jenkin were sent here to see me about my telegraph instrument. Whilst I was describing the operation of printing the signs on the paper coil Mr. Jenkin impetuously asserted that it would be impossible to hold the paper and to release it on printing each sign. I assured him that it could be done by utilising the same lever that operated the printing to clamp the paper. He immediately declared this to be quite impossible, and, appealing to Sir William, repeated that it would be a mathematical impossibility. (He had left out of his calculation the thickness of the sheet of paper.)

Uncovering an instrument, I requested Mr. Jenkin to start it, and to watch the simple arrangement which sufficed to clamp the paper and to print sixteen hundred definite and clear signs in a minute. The mathematician bowed to the mechanician, and there the matter ended, and there it still remains.—Yours, &c.,

RICHARD HERRING.

LITERATURE.

Electrolysis: a Practical Treatise on Nickeling, Coppering, Gilding, Silvering, the Refining of Metals, and Treatment of Ores by means of Electricity. By HIPPOLYTE FONTAINE. Translated by J. A. BERLY. Thirty-four illustrations. [E. and F. N. Spon.]

The English student can hardly expect to improve upon the works of Dr. Gore in the subjects connected with electro-disposition, but they will find in this book of Mr. Fontaine's some supplementary information in the introductory chapters which is interesting and useful; in fact, it is this supplementary value which renders the work at all serviceable. M. Fontaine's experience and scientific attainments in this special direction are not conspicuous, but he possesses a certain ability to put what he knows in a simple manner. It must be mentioned that the work was not written for an English public, but to fill a gap in French technical literature, which boasts "only two practical treatises on electrolysis," and these are antiquated. Under these circumstances we congratulate our French brethren upon having obtained a compilation, the practical part of which is extracted chiefly from English authorities. The preface, while giving us these facts as to French literature, mentions six well-known books in English and seven in German, showing there is no dearth of treatises on electrolysis in those countries. The introductory portion of the book occupies the first hundred pages, and deals with preliminary notions on units, electrolytic laws, work absorbed in electrolysis, tabular data, batteries, and dynamos in seven chapters. We are sorry to be unable to give any credit to the tabular data, and think that a book issued in the year of grace 1885 should in its electro-deposition take cognisance of Lord Rayleigh's determination as regards silver, from which such figures take a new and more accurate start. The fact that the tables given contain figures based upon old experi-

Digitized by Google

ments seems to indicate that neither author nor translator are familiar with the most recent work. Then, again, the chapter on batteries is altogether deficient. It is merely a descriptive list of different cells, almost without a word to indicate to the reader which is the best to use, or why it is the best. The chapter on "Work Absorbed" is far and away the best of this introductory portion, and indeed may be said to be excellent. Coming now to the practical portion, we find it contains a very fair *resumé* of what has been published in previous book upon the subject, and the best feature of this part is that the authorities for the information are freely given. We, however, prefer the authorities to the compilation. The translation would have been better by an Englishman who knew the French language school-boy fashion rather than by a Frenchman who knows English school-boy fashion.

PHYSICAL SOCIETY—November, 1885.

Mr. G. M. WHIPPLE described and demonstrated experimentally the process of testing thermometers at and near the melting-point of mercury as carried on at Kew. About 20lb. of mercury are poured into a wooden bowl and frozen by carbonic acid, snow, and ether ; the mercury is stirred with a wooden stirrer, and the snow is added till the experimenter feels by the resistance to stirring that the mercury is freezing. The stirring is continued for some time, which causes the mercury to become granular instead of a solid mass. The thermometers are then inserted together with a standard and compressed. About 100 mercury or 40 spirit thermometers can be thus examined in half an hour, using about 200 gallons of carbonic acid gas composed sufficiently to form the snow. The bowl, ether, and mercury are cooled first to 10°C. by an ordinary freezing mixture. The average correction at the melting point of mercury is now less than 1°F. ; when the process was introduced in 1872 it amounted to 5°, but has steadily decreased.

"On the Electromotive Force of Certain Tin Cells," by Mr. E. T. Herroun. Mr. Herroun has examined the electromotive forces of cells in which tin in a solution of its salts was opposed to copper, cadmium, and zinc in solutions of their corresponding salts, the solutions being of equal molecular strengths. The salts used were sulphates, chlorides, and iodides, and the cells were of the ordinary Daniell form, with a porous vessel. To prevent the formation of basic salts it was necessary to add a little free acid to the solution of the tin salt, and to counterbalance the influence of this acid upon the E.M.F. as far as possible an equal proportion of free acid was added to the other solution.

Prof. G. MINCHIN pointed out the importance of performing these and similar experiments upon tin in the dark, as by allowing light to fall upon the tin plate a considerable photo-electric effect would be obtained. Prof. Fleming insisted upon the great importance of temperature corrections in all experiments upon two-fluid cells.

"On the Law of the Electro-magnet and the Law of the Dynamo," by Prof. S. P. Thompson. It cannot be said up to now that any particular law has been generally accepted giving the relation between the current in the coils of an electro-magnet and the magnetism induced by it in the core. Many empirical formulæ have been given, most of which are entirely wrong. One, however, recently enunciated by Fröhlich gives a relation which agrees very closely with observed values. This formula is $m = \frac{i}{a + b\,i}$, where m is the magnetic moment of the core, i the current, and a and b constants depending upon the geometrical form of the magnet and the nature and previous history of the iron core. Fröhlich obtained this relation by experimenting with a series dynamo. It is purely empirical, but since it agrees so well with the facts as to give values for the magnetism of the core agreeing almost within experimental error with those observed, there is great probability of some law being at its base. And this law Prof. Thompson believes to be one that was stated years ago by Lamont—"The magnetic permeability varies with the quantity of magnetism the iron is capable of taking up." This may be expressed by the formula

$$\frac{d\,m}{d\,i} = k\,(\mathrm{M} - m).$$

Integrating which and expanding $e^{-k\,i}$ in powers of i

$$m = \mathrm{M}\,k\,i\left\{1 - \frac{k\,i}{2} + \frac{k^2\,i^2}{6} \ldots\right\}$$

Expanding Fröhlich's equation in powers of i we get

$$m = \frac{i}{a}\left\{1 - \frac{b\,i}{a} + \frac{b^2\,i^2}{a^2} + \ldots\ldots\right\}$$

If it is not great these expressions will coincide in form very closely, and the results lead Prof. Thompson to accept Lamont's expression as being that of a real physical law.

Prof. PERRY suggested that Lamont's law gave good results, from its being an approximation to Weber's theory of induced magnetism ; but Prof. THOMPSON maintain that it represented observed facts better than that theory, which, as developed by Maxwell, shows a decided discontinuity in the process of magnetisation not actually observed. Prof. FLEMING remarked upon the similarity of Fröhlich's expression to that for the current through a voltameter, the part $a + bi$ corresponding to the apparent resistance which may be considered in this case as the resistance to magnetisation of the core-air circuit, and which, like that of the voltameter, varies with the current.

COMPANIES' MEETINGS.

The West India and Panama Telegraph Company (Limited).

The seventeenth ordinary general meeting of the members of this Company was held at the City Terminus Hotel, Cannon-street, on the 18th inst. Mr. C. W. Earle presided.

The SECRETARY (Mr. R. T. Brown) read the notice convening the meeting and the minutes of the last meeting, which were confirmed. The report, which has been published in *The Electrician*, was taken as read.

The CHAIRMAN said: Gentlemen, the report, I think, is the shortest we have ever published, and the reason of that is that there has been very little of an eventful nature in the half year to refer to, and the accounts themselves practically tell the whole story. My remarks will also be very short, for the same reason. The balance of revenue over expenditure is almost the best we have ever had as yet. It is £1,190 in excess of that of the corresponding half year of 1884; and with the exception of one previous instance, in 1878, when it was about £1,000 better than now—which was an exceptional time, owing to certain windfalls we had in the chartering of our ships, and so on—the past six months has been the best first half year we have had to report on. Upon the expenditure side of the accounts I have very little to say. The respective amounts of the different items are very much the same as they were before. I have had a letter from one shareholder remarking upon the expenses of the ships in harbour. I presume that that gentleman thinks that these ships of ours go into harbour in the way you would lay up a collier. The fact is that, whether the ship is at sea or in harbour, the difference in the expenses is very trifling. The principal cause of difference is the expenditure on coal while steaming. The ship has to be ready, with equipments, with the technical people on board, the electrician, the officers, and crew ; it has to be kept up as a man-of-war—in fact, ready for immediate service. A cable breaks, and in a few hours the vessel must start to effect the repair. Therefore, although the expenses appear large when a vessel is in harbour, there is no possibility of reducing them. You must have the ship in constant readiness to make repairs, and it would be quite impossible in the West Indies—in London even—to get a crew together in the short time in which it is necessary to be at work on a broken cable. I may say that I am a great stickler for economy. I should not wonder if I heard that some of my friends connected with this business had termed me a "tremendous screw," and when I am spending your money I feel that I ought to be "a screw." However, as to that matter, if I were ever to attempt to relax the purse strings, I think my colleagues on both sides of me, and also the excellent permanent officers of the Company in London would pull me up. Upon any question of expenditure I think we could justify ourselves to the utmost. The traffic returns, although they have been good for us in this half year—the first half year—I am sorry to say, show a decrease in the current half year, as you may have observed, from our published returns of about 10½ per cent. This is disappointing, but still, having in view the great commercial depression that pervades the world, and which is particularly severely felt in the West Indies, I do not know that it is very much to be wondered at. I think the wonder is, perhaps, that we have not felt it sooner. I hope a better time is coming for all countries in the matter of trade, and certainly any revival would benefit us in the West Indies in the sugar business. When I last addressed you I mentioned that there had been a rise in the price of sugar, but since then there has been very little advance, and sugar is at very much the same figure as when I last addressed you. But, after all, the fluctuations of our traffic receipts have not so much to do with our prosperity as the amount of repairs. If we have a light season in repairs we shall have very much better returns to put before you. The cables are, I think, giving less trouble than any used to. We have put in a large amount of new cable in our repairs from time to time, and I think that comparative freedom from interruption is showing itself. I announced to you last year the repairs of the original Jamaica-Porto Rico cable. That has given us no trouble since. That cable had been inoperative for 10 years. It is an important section of 700 miles. We put in 232 miles of new cable, and it has worked most satisfactorily ever since—in fact, during the interruption to the other cable it maintained communication with the whole of the West Indies, which would otherwise have been cut off. We have another difficult job before us. The cable between Santiago and Jamaica has been inoperative very much in the same way as the Jamaica-Porto Rico cable. In the year 1878 we laid a duplicate cable there, which has worked perfectly ever since ; and we have now to turn our attention to the old Santiago-Jamaica cable. It lies in very deep water. Some of the soundings show a depth of 3,000 fathoms. We have tried to lift it, but hitherto we have not been able to get it up to the surface at that very great depth. Its position, too, is dangerously near the other cable. I think in places they are only about six miles apart, and if you consider the operation of lowering a grapnel three miles into the sea, and attempting to recover the cable at that distance from the surface, without any bearings to guide you, you may fancy what nervous work it is, lest we should get hold of the other cable. We have ordered the "Grappler" home to take out 250 miles of cable, and we shall have an opportunity of consulting the captain of that ship, with whose experience in recent work on that cable before us we shall, I think, be able to form some plan of operations. I hope before we meet you again we shall be able to say that that cable has been put in order ; but it is impossible to say what amount of new cable may be required. No doubt we must abandon some of the old cable, but whether all will have to be replaced by new cable I cannot say. It is a matter of 150 miles, and it may take a very considerable amount of cable to repair it. I do not know that anything more occurs to me to remark

Digitized by Google

upon. As long as the West Indian trade is in its present low condition we cannot expect any increase of revenue; and we cannot certainly expect any increase of subsidies in the depressed state of the West India colonies. If we could only get our cables to be more durable, and save expenditure on them, we should have a more prosperous condition of affairs to report to you. I now beg to move the following resolution :—

"Resolved, that the Directors' report and accounts to 30th June, 1885, submitted to this meeting be, and the same are hereby received and adopted, and that as recommended by the Board a payment of 9s. per share on account of arrears of dividend on the first preference shares be and the same is hereby declared."

Mr. WILLIAM FORD briefly expressed his pleasure in seconding the motion.

Mr. GUESDON said he desired to congratulate the shareholders on the very satisfactory position in which the Company stood, and to recognise the firmness which the Directors had shown in building up a reserve fund. It was a matter of the highest importance to all companies that a good reserve fund should be held, and perhaps this was of more importance to this Company than to most others. He would also congratulate the Directors on the nature of the investments which had been made on account of the reserve fund—investments which would not place them in any difficulty if they wanted money. The reserve fund was large, no doubt, and he hoped it would go on increasing till the Board felt that the Company was strong enough to pay the balance due on the preference shares. No doubt they were all anxious for a good dividend, but the question of primary importance was the stability of the Company. As to the depreciation of the ships, they had a very respectable sum for that. He supposed that the two ships were put down at what they originally stood at in the books. He also noticed an amount of £1,820 for insurance. He would like to have some information as to the cost of the insurance, because in a certain company a few years ago he introduced a scheme of insuring the ship among the shareholders. That was done in a way not to cause the slightest risk. The shares were deposited at a very small price compared with their market value, and they were deposited without reference to the position of any shareholder as the amount underwritten. He merely suggested that for the consideration of the Directors. It was better to keep among themselves any money they could keep. He supposed the £1,820 would indicate a sum not insuring the full value of the vessels.

The CHAIRMAN : They are insured for their full value.

Mr. GUESDON thought in case of average they stood in a very bad position.

The CHAIRMAN : We found the advantage of it in the case of the "Investigator." It is not the market value of the vessels that we insure on, but at what we could replace them.

Mr. GUESDON (continuing) said he would merely throw out the suggestion he had made for the consideration of the Directors—whether with such a large depreciation it was good policy to insure their ships up to their full value. There was an amount of £74 in the statement of general expenditure in London. The secretary had sent him a communication containing the information he had asked for as to how that item was composed, and he presumed it included nothing more than was stated. He, however, had found that lunches formed a considerable item in the expenses of joint stock companies.

The CHAIRMAN : Is there not a postcript there ? Mr. Guesdon called at the office, and afterwards sent a letter asking for the particular items forming that £74. I suspected he had lunches in his eye [laughter].

Mr. GUESDON : I had.

The CHAIRMAN : When the secretary put his letter before me I said : Give Mr. Guesdon all the details, and put in a postcript "no lunches" [laughter].

Mr. GUESDON said he had not noticed the postcript, not having read the letter with sufficient care. As to the great question of the cost of management, taking the average, which he presumed would be the case in most joint stock companies, the Directors held a meeting once a fortnight.

Mr. FORD : Once a week.

Mr. GUESDON : Then you are a very active Board.

Mr. FORD : And we find plenty of work to do.

Mr. GUESDON : Then, in that case, it would only cost £40 for each Board meeting ; but that was very large in a company like theirs. He said that without any idea of disparaging the services of the Board, for he believed that the Company was thoroughly well managed. Still, the amount represented a very large expenditure for them to incur. He had been pleased to hear the Chairman state that he was a great "screw," and he would be very glad if the Chairman would apply the screw at home. He noticed that the present market value of the whole of the stock held by the seven Directors represented £3,700, and while he did not wish to be invidious, and would be very unwilling to point to the holding possessed by any one member, he wished to say that there were two members of the Board who held about two-thirds of the amount he had stated. Consequently the other five members would receive annually for their fees rather more than the whole stake they held in the Company. The question in his mind was whether the Directors were not in excess of the number required by the necessities of the Company, and whether, both in number and amount paid, there could not be a reduction. He would move no resolution on the subject, but if the number of the Directors were reduced, and the remuneration brought to something like £1,000 or £1,200 a year, it would be a very acceptable increase to the revenue of the Company.

Mr. HORA reminded the shareholders that the Directors took office under certain conditions, and certain fees were promised. The matter had been thrashed out at previous meetings. The Directors had intimated that they were quite willing to place their seats at the option of the shareholders at any moment.

The CHAIRMAN, in reply, said, with regard to the question of insurance we pay between six and seven guineas per cent.

Mr. GUESDON was understood to say that he would give any security for a portion.

The CHAIRMAN : We will consider the question you have placed before us. Sir James Anderson reminds me that there is one thing shareholders might not like in insuring, which is protection against collisions. If the ship we collided with and sank was a valuable ship, it would be a serious matter, and we are protected from that now.

Sir JAMES ANDERSON : It is not your own ship only that you insure against.

Mr. GUESDON : You are only liable for so much per ton, not the value of the ship.

The CHAIRMAN : Well, we will consider what you have said. The question of the Directors, as Mr. Hora has said, has been thrashed out at almost every meeting we have had, and Mr. Guesdon in 1881 made a very vigorous attack on us in the same direction ; but after an explanation had been given (I have before me what you said on that occasion), you asked for everything that you had said to be expunged, as you had spoken in ignorance of the conditions on which the Company had been remodelled.

Mr. GUESDON observed that one was privileged to review one's decision of four years ago. The simple question, however, was whether the appointment as a Director was one for life.

The CHAIRMAN : Practically you discussed the question yourself then, and were of opinion that your remarks were not quite tenable. (Having quoted from the shorthand notes in support of this view), he continued : We were called into office at a critical moment. The Company had never up to then earned a farthing, and was practically in a bankrupt state. The present Board had had nothing to do with the Company then, and they were called in to do the best they could for a very tottering concern, and certain terms were held out for their remuneration. I have always said that I am perfectly willing to place my seat at your disposal, but as long as we remain here we shall expect to draw our fees.

Mr. VEARS said he regarded the complacency of the second preference shareholders as extraordinary ; and he was only an ordinary shareholder in the Company, a position which was something shocking. The facts laid down in the report were undeniable ; but surely there was some equity in the case. He said that the Directors were holding to the policy of these large additions to the reserve fund.

Mr. FORD : No, no.

Mr. VEARS : How am I to understand Mr. Ford's attitude ?

Mr. FORD : By seeing the diminished amount placed to the fund. You will find that in the last three half years we have reduced that amount.

Mr. VEARS : Still, you have added to it in the aggregate.

Mr. FORD : Certainly, because we think the amount has not reached an amount sufficient for our purpose.

Mr. VEARS, continuing, said he had no doubt that the Directors believed in their policy as to the reserve fund, but he maintained that, if he could speak of the equity of the position, he might ask for something for the ordinary shareholders. The character of the investments had been lauded by Mr. Guesdon, but he saw that they were getting 4 or 4½ per cent. from them, while they were paying 6 per cent. for their debentures. If the reserve fund could be made less and the ordinary shareholders could receive some return, the Directors would have the pleasure of knowing the benefit they had conferred on those unfortunate individuals, and he felt that they would also be freer in their consciences [laughter].

The CHAIRMAN : I am afraid our consciences would drive us to pay the unpaid dividends on the preference shares before we paid anything to the ordinary shareholders. As to the debenture debt, that is not due till the end of the coming year. When that time comes, no doubt, we shall be able to make some other arrangements. I do not suppose we shall be obliged to pay 6 per cent. again. At the time we raised that debt we had practically no reserve fund.

Mr. FORD : There was no back to the Company.

The CHAIRMAN : We have very much improved in our position since then. In answer to a remark of Mr. Griffith, the Chairman said : I stated that I would consider Mr. Guesdon's proposal as to insuring the ships. It is a new proposal to me.

Mr. GRIFFITH said it was also new to him. If they could obtain the benefit suggested by Mr. Guesdon it would be an advantage. On the other hand, they must remember that the insurance of ships was very hazardous, and that unless persons were fully competent to meet the risk they undertook, it would not be wise for the Board to insure in the manner suggested. He thought the Directors ought most carefully to consider any step they might take in the matter. As to what had been said about equity, contracts were contracts, and according to English law there was no equitable interpretation of a contract—the terms of the contract were upheld. If, however, the Company continued to advance as it had in the last six months, no doubt the second preference shareholders, and afterwards the ordinary shareholders, would receive something. The reserve fund was growing, and the Board, perhaps, might not think it would be necessary to add much more to it beyond the interest derived from the investments.

The CHAIRMAN : With respect to the remarks which have been made about the reserve fund, you know that this is properly speaking a depreciation fund. It is depreciation which goes on from year to year, and which we have to meet. No doubt we were very much behind with our reserve fund, and we had to build it up more rapidly than it may be necessary to do in future years. I do not think I am going too far in saying that there may be some relief to the shareholders as to this question of the reserve fund ; but the reserve fund is calculated on the basis of so many years' life of the cables and the interest we are getting on secure investments. It is constantly rolling up, but until it reaches what would replace the cables I cannot hold out any hopes that additions to the reserve fund will absolutely cease, though I think they will be reduced.

Digitized by Google

It all, however, depends on circumstances. We may have to draw upon that reserve fund. This cable repair that we have now to work at may cause us to dip into it.

Mr. GRIFFITH: But there is a depreciation fund.

The CHAIRMAN: What could you replace the cables for?

Mr. GRIFFITH: You can lay a cable to America for £400,000.

Mr. HENRY WEAVER: Would you introduce me to a contractor who would do that?

Mr. GRIFFITH: That was the price paid by the Anglo-American Company.

Mr. WEAVER: No; I beg your pardon.

Mr. GRIFFITH stated that in the Cuba Company they paid an annual sum to the contractor, which was part of the original purchase money, and he in return for that undertook to repair the cable.

The CHAIRMAN: They have a reserve fund as well. That is only as to one cable, as to which, no doubt, they made an excellent arrangement. It was cable lying on the hands of the Company from whom they purchased it.

Mr. FORD: It was an exceptional arrangement. The people had the cable on hand and wanted to get rid of it.

A SHAREHOLDER asked when the ordinary shareholders were likely to receive a dividend.

The CHAIRMAN: You can judge from the accounts. Our first duty is to the preference shareholders. We must first wipe off the accumulation of arrears on the preferences, and we are taking one step towards it now. If our repairs cost us very much less and our position improves we shall make more progress in paying off that liability; but before that is done I see no hope for the ordinary shareholders.

Mr. BARHAM said that though he was rather a large shareholder in the concern, he did not think they ought to starve the reserve fund. He hoped the Directors would have the moral courage to keep that going on, as the future of the Company depended upon it.

A SHAREHOLDER said he hoped when the present debentures fell due the new ones would be offered to the shareholders first.

The CHAIRMAN: The debentures are not due till the end of next year, and we cannot really say what we shall do so long beforehand.

Mr. ROBINSON KENDAL said he hoped that before that time came the Company would be in a position to pay off the debentures and not be obliged to renew them. Mr. Vears had asked whether the Directors could do anything for the ordinary shareholders. If he (Mr. Kendal) thought they could he would move a resolution on the subject. As to the question of insurance, he trusted that the Board would not for a moment listen to the nonsense that had been talked at that meeting in regard to that question. Insurance at all times as to steam vessels was a delicate and hazardous matter, and it was eminently so in regard to cable steamers. He trusted that the ships would be insured in very good offices, and up to the full amount, so that the Company could lose nothing; and he hoped the Directors would not (he was sure they would not, as business men) entertain any question of dealing in the way suggested with the insurance of the Company's ships.

The CHAIRMAN then put the resolution, which he declared carried unanimously, adding that that closed the business of the meeting.

On the motion of Mr. GUESDON, seconded by Mr. BARHAM, a vote of thanks was passed to the Chairman.

The CHAIRMAN having acknowledged the vote, the proceedings terminated.

The Pilsen, Joel, and General Electric Storage Company.

The fourth ordinary general meeting of the shareholders of this Company was held on Thursday last at the City Terminus Hotel, Cannon-street, Sir Rawson W. Rawson, K.C.M.G., C.B., presiding.

The SECRETARY (Mr. W. H. Trentham) read the notice convening the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN then said that the report, which was a very short one, laid before the shareholders frankly and fully the position of the Company at the present time. The Directors had succeeded in carrying out the policy which was approved at the last two meetings. They had got rid of the obligations connected with their factory and office; they had reduced the expense of management to a minimum; they had put the Company in a way of working at a profit; and they had held in view the most important point to the shareholders, namely, to avoid being under the necessity of making any further call. They had now invested on behalf the Company £3,000, besides the balance in hand and at the bankers. They were working at a profit, and they had every reason to hope that the difficulties with regard to the arc light would be overcome. They must remember that their patent was that for the arc lamp, which was not available for lighting houses or small areas, but was specially applicable for large areas, streets, factories, and suchlike places. The time was now at hand when the public and the legislature would equally recognise the necessity of removing the restrictions which had hitherto prevented the development of the electric light, and the Company had every indication at the present moment, by the tenders which they had been called to make, by the enquiries that had been made at the office, by the general acceptation of the Pilsen arc lamp as being practically the best before the public, and by the fact that their patent was one which could not be superseded—it might be improved upon by themselves, but it could not be superseded by others—that there was a good future for the Company. The Directors had succeeded in avoiding what many wished—the winding up of the Company and the distributing of the assets, such as they were. They had moreover placed the concern on a footing which he trusted would enable them, on the present economical scale of working the business, to give the shareholders something in return for the capital which they had invested. Having invited discussion, he concluded by formally moving the adoption of the report and accounts.

Mr. ELLIS seconded the motion.

The CHAIRMAN, in reply to Mr. Fyfe, said that the valuation of the Company's property was made by the manager last year, and it was founded upon the usual principle of allowing a reasonable amount of depreciation. This year after their experience of the auction, and with the advice and assistance of their auctioneer, who was exceedingly skilled in the valuation of machinery and such stock as the company possessed—the property was revalued, and was put down at what the auctioneer expected it would sell in the market if they were obliged to sell.

Mr. HORACE W. SCRIVEN, in further reply to Mr. Fyfe, assured that gentleman that the Board had not tried to make the stock of less value than it would fetch in the market, but they had studiously avoided putting upon it any fanciful price.

The CHAIRMAN, at the request of Mr. King, pointed out that a printers' error in the published accounts made it appear that the capital as reduced was 28,000 shares of £4 each, of which £2. 5s. had been paid, whereas it should have been £3 each. £1 had been written off as lost, and £1 had been written off as reduced, so that the liability was really 15s. per share.

Mr. FYFE complained of the price at which the Joel lamps were sold.

Mr. JOEL explained that the Secretary wrote to him and said that an offer had been made to the Company of £20 for the lamps, and asked whether he (Mr. Joel) would not give them more than that figure. He accordingly gave £5 more for them in order to prevent their being forced on the market, and he had them now.

The CHAIRMAN said the Directors had done their best. They had had a very toilsome year in trying to advance the interests of the shareholders. If gentlemen thought that better things ought to have been accomplished, he wished that they had only been in the Directors' places.

A discussion then ensued as to the propriety of cancelling all those shares on which arrears had not been paid. The general feeling of the meeting, however, was in favour of leaving the question to the discretion of the Board.

The retiring Director, Sir Rawson W. Rawson, was subsequently re-elected to his seat at the Board, and the auditors, Messrs. Broom, Hays, and Akers, were reappointed.

By another resolution, after a short discussion, the remuneration of the Directors was fixed at £100 each, and a vote of thanks having been accorded to the Chairman for presiding, the proceedings terminated.

NOTES.

THE ELECTRIC LIGHT AND MADRAS.—The Madras Club has been lighted with electric light as an experiment.

APPOINTMENT.—Señor Don Saturnino Islas has been appointed Director-General of Telegraphs to the Mexican Government.

POSTAL APPOINTMENT. — Mr. A. S. Roberts, assistant superintendent, Central Telegraph Office, has received the appointment of Postmaster at Normanton.

THE VIENNA ELECTRIC RAILWAY.—The electric city railway project of Messrs. Siemens and Halske at Vienna, Austria, has received the sanction of the authorities.

THE BLACKPOOL ELECTRIC TRAMWAY.—The electric tramway on the promenade in Blackpool is now in full working order, and cars driven by electricity run daily.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 13th and 20th inst. amounted to £3,063 and £2,633 respectively.

WHEATLEY v. THE CONSOLIDATED ELECTRIC COMPANY.—Owing to the sudden death of Mr. J. Beaumont, who was engaged in this case, the further hearing has been adjourned.

THE ATLANTIC COAST.—Advices from Philadelphia state that the high tides continue on the Atlantic coast, from Chesapeake Bay to New England, interfering with the shipping, railroads, and telegraphs.

THE TELEPHONE IN FRANCE.—The Havre Chamber of Commerce has addressed a note to the Minister of Posts and Telegraphs relative to the inefficiency of the telephone service between Rouen and Havre.

THE WAR WITH BURMAH.—A telegram from Calcutta reports that it is officially announced that Press telegrams from the seat of war in Burmah have been stopped. The reason for the step is not known.

THE SERVO-BULGARIAN WAR.—A telegram from Sofia, dated Nov. 22, says:—"On the strength of the St. Petersburg Convention of 1875 the Diplomatic Agents here have been informed that they may not telegraph in cipher."

LUMLEIAN LECTURES, 1886.—Dr. Stone has been nominated by the Royal College of Physicians to deliver this course in April next. He has chosen as his subject "The Electrical Conditions of the Human Body—Man as a Conductor, Condenser, and Electrolyte."

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the weeks ended 13th and 20th November were £2,359 and £1,885, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

RUSSIA AND CENTRAL ASIA.—As briefly announced in our last issue, the telegraphic line is now open to Penj-deh, the section from Merv to that place, a distance of two hundred and ten versts, having been hastily constructed in view of the greater facilities it would afford to the Commission of Delimitation.

THE INDUSTRY AT MONTREAL, CANADA.—The equipment of the American Electric Manufacturing Company's new factory at Montreal is about completed, and will soon be put in operation, with advance orders on hand for dynamo machines and lamps sufficient to keep it running from four to six months.

MORE ATLANTIC CABLES.—We strongly advise that not a single farthing be invested in any new Atlantic cable company, as it is impossible that any return can be realised from such investment, and we emphatically protest against any attempt being made to obtain money from the public for this purpose.

A MISSING BALLOON.—Advices from Paris state that a balloon, named La Vénus, containing MM. Falubas and Thomas, and illuminated by the electric light, started recently from Montmartre on its aerial voyage. Nothing has been heard of it since, and it is feared that an accident must have occurred.

THE ELECTRIC LIGHT FOR TRAWLERS.—The series of experiments lately carried out upon the North Sea trawling vessels, with a view to lighting them by electricity, has, on the whole, proved satisfactory. The lighting of fishing boats by electricity would be invaluable, were it not for the heavy cost involved in this project.

A DIRECT CURRENT TELEPHONE.—A contemporary gives a glowing account of a telephone invented by Mr. Guthrie, of Leesburgh, U.S.A. As far as we can make out the instrument is operated on the closed-circuit principle, as in telegraphy, contact being made and broken by the vibrations of the diaphragm when spoken against.

AN AMERICAN TELEPHONE STORY.—This conversation is said to have actually occurred at the Central Hotel, Cherry Valley:—Man: "Is there a telephone here?" Operator: "Yes, sir." Man: "Can I send a message to Little Falls?" Operator: "Certainly. To whom do you wish to send?" Man: "I've forgotten the man's name; that's what I want to telephone for."

THE KALAHARI DESERT.—It is said that a hot electric current sweeps over the Kalahari desert from north to south, at the end of winter. In connection with this wind it has been asserted that the Bechuanas knew of the electric spark ages before it was produced by Dr. Franklin. The wind seldom blows from north to south; that from the north is hot, and from the south cold.

BOOKS RECEIVED.—"The Turkish Bath in Diseases of the Heart, Obesity, and Atrophy," by Richard Metcalfe. London: John Heywood.—"Examples of Exercises given in the Natural Philosophy Class of Glasgow University, with Indications how to Answer Them," by M. Maclean, official assistant to the Professor of Natural Philosophy in the University of Glasgow. Glasgow: James Maclehose and Sons.

PERSONAL.—Mr. G. W. Morrison, Town Clerk of Leeds, has received from the Prime Minister a letter stating that the Queen intends conferring upon him the honour of knighthood, especially in commemoration of the fact that he was the originator of the Municipal Corporations Jubilee, recently celebrated. Mr. Morrison gave evidence before Mr. Chamberlain's Committee on Electric Lighting, the said evidence consisting of a recapitulation of the views of an electrician who was even more of an amateur than Mr. Morrison.

IS CAPACITY VARIABLE?—In the current issue of our contemporary, the *Electrical Engineer*, there appears an article in which the above question is asked. The writer is of opinion that long exposure to the heat and humidity of a tropical climate has a deteriorating effect upon both condensers and submarine cables, and also points out that the observed capacity of a cable in comparative deflection tests must vary with its insulation resistance, in that there is a variable loss of current in the interregnum between charge and observation.

In Liquidation.—Notice is given that a general meeting of the shareholders of the Mediterranean Extension Telegraph Company (Limited) will be held at the Cannon-street Hotel, on Monday, the 21st prox., at one o'clock, for the purpose of having the accounts of the liquidators laid before them, showing the manner in which the winding up of the affairs of the company has been conducted, and the property of the company disposed of, and hearing any explanation that may be given by the liquidators. Messrs. Ashley Ponsonby and John G. Griffiths are the liquidators.

Cambridge University.—The adjudicators of the Smith Prize announce that the essay by Mr. Charles Chree, B.A., Fellow of King's College, on "Elastic Solids," and the essay by Mr. Alfred North Whitehead, B.A., Fellow of Trinity College, on "The General Equations of Hydrodynamics," are deserving of honourable mention. The subjects of the essays, which were declared of equal merit for the prizes, were "The Distribution of Electricity on the Circular Disc and Spherical Bowl," written by Mr. E. G. Gallop, and on "Systems of Circles," written by Mr. R. Lachlan.

Telegraphic Communication with our Colonies.—We have good reason to believe that the present Government has, during its already short tenure of office, considered very carefully the advisability and possibilities of connecting by cables completely under English control most of our outlying dependencies not yet so connected. Several plans have been suggested so as to obtain as far as possible alternative routes, and not to be compelled to depend solely upon single cables. We have for a long time strongly advocated the adoption of some system, and trust that the work will be vigorously pushed forward.

Telegraph Stores.—The Directors of the North Eastern Railway are prepared to receive tenders for telegraph apparatus and telegraph wire and line stores, in such quantities as they may require, during the six months ending 30th June, 1866, delivered carriage-paid at the company's telegraph stores at York. Payment for each month's delivery will be made at the end of three clear months, or in cash less 2½ per cent. discount. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent in to the secretary at York, sealed and marked "Tender for Telegraph Stores," not later than noon on Tuesday, the 1st December.

Gas in Glasgow.—According to recent statistics of the street lighting in Glasgow, it appears that for the year ending May 31st, 1885, there were in the public and private streets, courts, &c, 12,766 lamps, consuming 96,484,973 cubic feet of gas, which, at 3s. 6d. per 1,000 feet, yielded to the Gas Trust £16,884. 17s. 5d. The estimated consumption in the public and private street lamps for the year ending May 31st, 1886, is set down at 103,323,543 cubic feet, and that of the stair lights at 72,124,808 cubic feet; being a total of 175,448,351 cubic feet. This quantity, at 3s. 3d. per 1,000 cubic feet, represents a payment by the Lighting Department to the Gas Trust of £28,510. 7s. 2d.

A Visitation of Earthquakes.—M. Delaunay, of Paris, predicts that earthquakes on a grand scale will occur next year either when the earth is under the influence of a planet of the first rank, such as Jupiter, or under that of a group of asteroids, or at a time when the sun and moon are nearest to our planet simultaneously. This specialist in earthquakes foretold the frightful catastrophes which occurred in South America in 1877. He announced a vast seismic disturbance in 1878, and the appalling disasters in the Indian Archipelago followed. He raised his voice of warning also before the late extensive shaking of the earth in Spain. It is no wonder that his latest utterances have caused considerable attention in various countries.—*Kuhlow.*

Continental Notes.—The installation put down in the shops of the Maison Boudet at Paris has been modified. Formerly the current was supplied from batteries of the Société le Chrome. Now, however, these have been displaced, and a dynamo, driven by a gas engine, substituted for them.—The Exposition du Travail closed last week.—It is said that the Cirque now in process of construction in the Rue Saint Honoré, Paris, will be lighted by electricity. The installation will consist of no fewer than 800 Edison 8 and 10 candle-power incandescent lamps, supplied from two Edison dynamos, and a battery of Barrier and Tourvielle accumulators, furnished by M. Duplay. There will also be a number of sun lamps supplied by alternating current machines on the Maquaire system.

The Electric Light and the St. James's Vestry.—At a recent meeting of this Vestry Board the Lighting Committee recommended, with reference to the letter from the West London Electric Lighting Company as to the delay in commencing operations under their order, that the company be informed that the vestry regret that the company should now appear to raise any objection to proceeding with carrying into effect the Electric Lighting Order obtained by them in 1884, until clause 27 of the Electric Lighting Act of 1882 has been altered, inasmuch as the company were fully acquainted with the provisions of the law before the order was granted to them, and that the vestry hope the company will take steps for carrying the order into effect without any undue delay. The report was accepted.

Isolated Plants in America.—According to recent statistics there are in America a total of 451 plants and 97,424 lamps, of which 368 plants and 78,432 lamps were of the Edison system. The company has, however, increased its output to 520 plants and 132,875 lamps up to October 1, or an increase, taking this basis, of 41 per cent. on plants and 69 per cent. on lamps. It is also worthy of note here that there are in use 88,000 lamps, additional, in central stations devoted wholly to the work of supplying the public in the same manner as do gas works. Another interesting feature of the work of the company in 1884-5 was the number of installations in exhibitions. The list is as follows:—Louisville, 5,000 lamps; St. Louis (permanent), 3,600; New Orleans, 5,000; Cincinnati, 1,200; Boston, 1,200; Milwaukee, 800; Philadelphia, 3,000.

The Commercial Cable Company.—It is rumoured in the City that an endeavour will shortly be made by the Commercial Cable Company to issue £600,000 six per cent. debentures. It will be remembered that this company has laid two cables in opposition to the existing Atlantic cable companies, at a time when there is no prospect of anything like sufficient work for the older cables. We are now told that another scheme is being promoted to lay an Atlantic cable *vià* the Azores. Surely speculative credulity will hardly go so far as this; but if foolhardy speculators should be found to make the attempt, we strongly advise the existing companies to fight, and to fight in such a manner that the opposition must end in perfect failure. Legitimate competition is all very well, but this is not legitimate competition, for it is absolutely impossible to put forward any good reasons for promoting such a scheme.

The Persian Gulf Cable.—It is announced that the new telegraph cable between Bushire and Jashk, in the Persian Gulf, has been successfully laid. On the 8th of October we stated that the steamship "Dacia," with Colonel Bateman-

Digitized by Google

Champain, R.E., the Director-General of the Indo-European Telegraphs, and Sir Henry Mance, C.I.E., the electrician, had started from the Thames with the first portion of the cable. The steamship "International," which left England with the other half of the cable a few days after her consort, met her at Jashk on the 12th instant, when the operation of paying out was commenced, and the whole cable, 530 miles in length, was laid in perfect condition on the 20th instant. Mr. D. W. Barker has received the following telegram from his son, Captain Barker, of the telegraph ss. "Dacia," now in the Persian Gulf:—"Shirez, 21st Nov., 9:10 a.m., and received in Worcester at 10:4 : Cable successful, all well."

QUERY TELPHERAGE?—An American contemporary says that there is on exhibition at No. 1, Pemberton-square, Boston, an ingenious model exemplifying a new system of rapid transit. The work is the result of years of labour by Mr. John A. Enos, a young electrician, and consists of a passenger car suspended from a rail upon which runs an electric motor. The latter is of the Daft pattern, and receives its power from an electrified rail, furnished from powerful steam dynamos. The cars may be either suspended in the air or move near the ground. The cars are lit by electricity and worked entirely from the inside. The elevated track, being a single rail, does not darken the street. A stock company is being formed to introduce the system in Boston. The patentees have about completed arrangements to put it in operation between Lynn and Nahant. The Legislature will be applied to for the granting of a charter and the right of way through the city.

AUSTRALIAN NOTES.—Advices from New South Wales report that the new system of paying for telegrams by postage stamps is now in operation in the colony. The working of the system in Melbourne was inquired into by Mr. P. B. Walker, Acting Superintendent of Telegraphs, and both Mr. Norton and Mr. Walker feel convinced that the new arrangements will prove to be very advantageous to the public.—South Australia now possesses about 5,500 miles of telegraph, and the length of wire is nearly 9,000 miles. In 1883 the gross value of the international messages was £251,277. Sawn jarrah poles are pronounced the best timber for carrying wires. The Transcontinental line was opened in October, 1872. The cost of construction was £338,059, or, including re-poling, &c., £479,175. Its length (from Adelaide to Port Darwin) is 1,975 miles. A line to Western Australia cost nearly £70,000. Communication was established between Adelaide and Perth in December, 1877.

TELEPHONE CHESS MATCH.—On Tuesday evening, through the courtesy of the National Telephone Company, a match at chess was played between four members of the Workington Chess Club and a like number of Maryport players. Four tables were arranged at Workington, at which sat Messrs. J. Higgins, D. Harkness, J. Urle, and J. C. Thompson. The various moves were spoken by means of the telephone, and the play went steadily and easily forward. The National Company made every arrangement for the working of the match at their offices at Workington and Maryport, and the interesting experiment was watched by a considerable number of invited spectators. The match is due to the arrangements of Mr. J. Higgins. Mr. Kirkwood, the local agent of the company, was present, and the officials received the congratulations of all present for the excellence of the circuit, and the ease with which the messages were sent and received. There was but one disputed move in all the games.

PROVISIONAL ORDERS OF THE BLACKPOOL CORPORATION.—Among the purposes for which the Corporation of Blackpool intend, during the coming Session, to apply for powers are the following:—The placing, removing, and prohibiting the erection of telegraph, telephone, and overhead wires. To revise and extend the powers of the Corporation under the Blackpool Improvement Act, 1879, for the production and supply of electric light, heat, and motive power. To break up and also to stop up, alter, divert, and interfere with, either temporarily or permanently, and if permanently to appropriate the site of and extinguish all right of way over and to cross over, under, or upon all such streets, roads, highways, bridges, thoroughfares, railways, tramways, rivers, streams, brooks, watercourses, sewers, drains, gas and water pipes, and telegraph and other electric apparatus, as it may be necessary or convenient to break up, stop up, alter, divert, interfere with, or cross for any of the purposes of the Bill, and to extinguish all rights of way and other rights in, over, or upon any lands to be acquired under the powers of the Bill.

AMERICAN ITEMS.—The New York Subway Company has been incorporated at Albany, with a capital of 5,000,000 dols., for the purpose of establishing electric communication underground in the City of New York, by the means of subways, cables and conduits.—The Fourth Electric Light Company applied for a franchise at Galesburgh, Ill., on 2nd inst.—The electric light is spreading rapidly in the American coal regions. Pottsville was lighted by electricity on the 16th inst., thirty arc lights being used as a beginning.—Denver, Col., will be lighted by electricity; incandescent lights are to be placed on every lamp-post. An electric railway is nearly completed in the same city.—General Hazen has gone from Washington to Boston for the purpose of superintending the laying of the new signal service cable that is to connect Nantucket with the mainland.—There is a project to put down a new street railway in Nahant, Mass., and electricity is to be the motive power.—Gas does not answer the requirements of the Brooklyn Elevated Railroad, which has a great many exposed stations. The company is in favour of incandescent lighting, and will in all probability try that system first on the new Fulton Ferry Station. If it proves satisfactory there, it will be adopted over the entire road.

A PROPOSED NEW CABLE.—Particulars will be found in our advertisement columns of an important undertaking, no less than the laying of a submarine telegraph cable between Halifax (Nova Scotia), Bermuda, and Jamaica, for which Her Majesty's Government are inviting tenders. The contractor must undertake to make suitable arrangements for the prompt transfer to and from the cables of the Atlantic and West India and Panama Cable Companies of all messages transmitted or intended for transmission by the proposed cable, so that a continuous and satisfactory service may be maintained between the United Kingdom and Bermuda and the British possessions in the West Indies. The subsidy may be for a term of twenty years, and will be payable at the end of each complete period of twelve months, provided that the cable has been maintained in good working order, and has been efficiently worked, and a continuous service between the United Kingdom and Bermuda and the British possessions in the West Indies has been in fact maintained. The communication must be established and in efficient working order within twelve months of the acceptance of the tender. The last day for the reception of tenders is Tuesday, the 15th proximo. They must be enclosed in sealed covers, marked "Tender for Bermuda Cable," must be addressed to the Secretary, General Post Office, E.C., and be delivered by 12 o'clock (noon) on that day. Her Majesty's Government do not bind themselves to accept the lowest or any tender.

REESE LIBRARY OF THE UNIVERSITY CALIFORNIA
Digitized by Google

THE LIGHTING OF THE CITY.—At a recent meeting of the Commissioners of Sewers Mr. Altman, in answer to Mr. Deputy Bedford, said the Streets Committee had had a large number of applications from different electric lighting companies, which were still under consideration. With regard to the offer that the Commission should take over the plant of a particular company, and carry the lighting out on their own account, the committee had seriously considered the matter, and were of opinion that if the Commission felt disposed to take up electric lighting on their own account it would be better to buy new plant. The Commission was handicapped to a large extent by the present Act, and if it were possible to amend it their work might be very much easier. He hoped to bring up a satisfactory report at the next court.—Mr. Deputy Bedford was informed that the people who lighted Holborn-viaduct were prepared again to light the whole of it with double light for £500 a year. This was one of the most magnificent entrances into the City of London.—Mr. Altman said the offer of that company was still under consideration.—Mr. Deputy Ashby understood the committee were to consider and report whether it had power, and if so, whether it was desirable for the Commission to undertake, at its own cost, the supply of electricity; and, secondly, to appoint an area and give an estimate of the expense.—Mr. Altman replied that the committee would meet two hours earlier for the purpose of considering that.

THE BALL UNIPOLAR INDUCTOR DYNAMO.—The novelty in the electric light system of Mr. C. E. Ball, of Philadelphia, and the feature that distinguishes it from all others is that it has two armatures, each of which rotates within the inductive influence of only one pole of a field-magnet, while other forms of dynamos have one armature rotating within the inductive influence of two poles. The promoters of the enterprise make the following claims as to the excellent qualities to be found in the Ball unipolar inductor dynamo :—"The current is very regular, and produces an unusually steady and uniform light. It will sustain at the same time two circuits of lamps, one of the arc class and another of the incandescent, or it will run either class independently. Its capacity and performance are very remarkable, which may be inferred from the fact that one dynamo for operating 20 arc lights weighs but 780lb., while 2,000lb. is a light weight for one of equal capacity of any other system. It does not generate undue and excessive heat in its armatures, and consequently they offer with it no cooling device or ventilating apparatus, such as blowers, air blasts, fans, &c. It possesses the prevention and requires no cure. It does not require to be run at an exact speed, and any power of ordinary uniformity will produce good light as regards its mechanical detail. The shaft is steel, the bearings are bronze, and the ironwork is forged. The commutators are composed of unusually pure copper, formed by a peculiar process, which gives it great density and secures a uniform wear. The wear of the commutators and the consumption of brush copper is remarkably slight.

THE TELEPHONE AND THE CORK CORPORATION.—At a recent meeting of the Cork Town Council, the Secretary of Committees reported that in accordance with an order of Council the system of telephonic inter-communication had now been established between the various corporate offices. The arrangement was manifestly calculated to facilitate the transaction of business within the corporate organisation, being the next best thing to a concentration of all the offices in one place. The value of this corporate inter-communication was likely to be greatly enhanced, as far as the public were concerned, by the fact that the whole of the system was placed at the service of persons who were subscribers to the Cork telephone system established at the General Post Office. One special advantage to subscribers to the telephonic system of the General Post Office consisted in being enabled to call up the fire brigade at any moment day or night through the subscribers' own telephone. During office hours this would have to be done by first calling the Post Office, the latter then calling the office in the South Mall, where they would be put through to the brigade station ; but at night, when the mayor's office was closed, the Post Office and fire brigade station were placed in permanent communication. Mr. Julian said the report was an important one and was very satisfactory. It would enable parties to see how they could communicate with the fire brigade at night, and he was of opinion that the communication that was established between the different offices by telephone would result in a saving far more than they would be obliged to pay for the telephone to the Post Office. He thought the mayor's residence should also be placed in communication with the system, so that they would be enabled to call upon him at any time his services might be required.

THOMSON'S SOUNDING APPARATUS.—As considerable misapprehension exists, says a contemporary, as to the precise limits of accuracy and the legitimate use of Sir W. Thomson's sounding machine by Her Majesty's ships, the Admiralty have issued a memorandum on the subject. The working of the machine is simple, but in the hands of men not thoroughly acquainted with it failure is very likely to occur when soundings are obtained in an emergency, especially on dark nights and in heavy weather, under which circumstances the apparatus is most of service. After referring to the advantages and defects of the machine, their lordships remark that the error in a tube will generally be greater at the greatest depths, as the scale is a diminishing one, and the graduation above the 50 fathom mark becomes rapidly very small. The presence of any matter in the tube affects the compression of the air as the space unoccupied by water becomes smaller. No confidence is to be placed in a single cast. A continuous line of soundings is ordered to be taken, but without dispensing with the ordinary casts of the deep sea lead. The utmost caution is to be observed in attempting to assume the ship's position from the coincidence of a line of soundings by the machine with the soundings on the chart. From the liability to small errors in reading, this may give very erroneous results where the water shoals gradually, unless the correctess of the tubes has been verified by one or more casts of the ordinary lead. None of Her Majesty's ships are, unless under special orders, justified in running for the land in thick weather, relying on this machine as an unerring guide. From ships supplied with the machine valuable information is looked for as to inequalities of the bottom on many shores not yet thickly sounded over, from the facilities offered, by the method of working it, to obtain frequent soundings. In all cases, however, of discovery of banks, or shoaler soundings than marked, the accuracy of the depth indicated should be checked by an up and down cast of the lead and line. There are frequent cases on record of reported discrepancies of soundings over large areas and of banks, given on the strength of Thomson's machine, which have been disproved when examied with lead and line.

TELEGRAPHIC COMMUNICATION WITH WEST AFRICA.—An important aid to the commercial development of the West Coast of Africa will be the telegraph cable which will before the end of next year extend along its shores, touching at the principal ports and reaching to the mouth of the Congo and to St. Paul de Loanda. There at present exists telegraphic

Digitized by Google

communication between Europe and Dakar, Senegal, *viâ* Cadiz, on the one hand, and between Europe and the Cape Verd Islands on the other. The cable steamers "Silvertown" and "Buccaneer" are now at work, connecting up the Cape Verd Islands with the mainland and prolonging the Senegal cable down the coast, so that in three or four months it is expected that Sierra Leone will find itself in duplicate telegraphic communication with Europe. The ports to be connected in this system of cables are the English possessions of Bathurst, Gambia, Sierra Leone, Accra, Lagos, and Niger; the French possessions of Dakar, Senegal, Conakry within 80 miles of Sierra Leone, Grand Bassam, Porto Novo, and Gaboon; the Portuguese possessions of Bulama, Bissao, St. Thomé, Principe, St. Paul de Loanda, and probably Congo. The Spanish Government are in treaty to have Fernando Po in connection with this system, and the German Government are also thinking of opening stations in the Cameroons district. The importance of this West African telegraph line to the development of commerce in these regions is self-evident, and has been recognised by the several Governments that have subsidised these new lines. When the cables are open for service there will be fewer of those surprise annexations of which we have had so many recently. In 18 months' time there will be a further extension of telegraphic communication along the coast, the Portuguese Government having contracted for the connection of Nova Redendo, Benguela, and Mossamedes; while the Government of Cape Colony has been authorised to subsidise a West African telegraph line, the laying of which will place that colony in duplicate communication with Europe, so that the colony will be independent of complications in Egypt. The completion of this line to the Cape gives a circle of communication round Africa, and consequently gives every point touched an alternative route. There have been recent complaints of the neglect of our West African colonies by the home Government, which does not seem to be devoting so much attention to this region as our more active French and German neighbours. France is steadily enclosing our colonies of Bathurst and Sierra Leone, by her acquisitions in the interior, and her extension of territory in this direction does not seem to be fully realised in London.—*The Times.*

THE ELECTRIC LIGHT IN NEW ZEALAND.—In October last a number of gentlemen proceeded to Mosgiel, near Dunedin, at the invitation of the directors of the Mosgiel Woollen Company, for the purpose of witnessing the illumination of their premises by the electric light. We understand that the directors, not feeling satisfied that kerosene lamps were adapted for night work, decided upon giving the light a trial. Accordingly, alternative tenders were invited and received from a London firm, a Christchurch firm, and Messrs. Fletcher and Co., of Dunedin. Acting on the advice of Mr. R. Clay Jones, electrician to the Union Steamship Company, Mr. Morrison, business manager for the Mosgiel Woollen Company, entered into arrangements witn Messrs. R. E. Fletcher and Co., for a 300 lamp service, and the light, after a fair trial, proved thoroughly satisfactory. The installation comprises an F2 Victoria dynamo, made by the Anglo-American Brush Electric Light Corporation, the Australasian patents being owned and represented by the Australasian Electric Light, Power, and Storage Company of London and Sydney, and who are represented in New Zealand by Messrs. R. E. Fletcher and Co. The machine supplies 300 Swan lamps of 20 candle-power each, at a speed of 450 revolutions per minute. In the colonies, the Melbourne General Post Office has three (900 lights), and the Victorian Houses of Parliament four (1,200 lights) machines of the same type and size as the one supplied to the Mosgiel Company. Several of this and smaller sizes are in use in New South Wales, and the New Zealand Government have ordered three for coast defence. The Union Steamship Company's new steamer "Mararoa" has also a 300-light Victoria dynamo. The lamps used are the new Swan-Edison. There are at present 239 lamps arranged in four main groups or circuits, as follows: No. 1 circuit—carding and spinning room 112 lamps, engine room 6, boiler house 4; No. 2 circuit—warping room 15, milling room 8, steam brush room 1, finishing room 16; No. 3 circuit—wool-scouring room 4, teasing room 2, wool-drying room 2, dye house 8, drying rooms 12, mechanics' shop 4, wool bins, store, and passage, 4; No. 4 circuit—offices 3, hosier rooms 6, stocking house 19, scouring house 2, outside lights 3, manager's residence 8. The weaving room has not been fitted up with the light at present, because the rooms are not worked at night. A few lamps were temporarily fitted up, however, and four looms shown at work, to enable visitors to judge of the advantage of the electric light for weaving. The lamps are suspended from the ceilings by neat plaid-plaited "twin" wires, and in most of the rooms are arranged so that whichever way they are looked at the rows are always in line, thus giving a very pleasing and orderly appearance. The majority of the lamps are fitted with conical metal reflectors, by which the bulk of the light is thrown downward upon the work, and so used to the best advantage. Some idea of the size of this installation, which is the largest in this colony (Rosslyn Woollen Mills, who also use a Victoria dynamo, coming next), may be gained from the fact that nearly one and a half miles of main conductor and fully two miles of branch wires have been used for running the various circuits. Every portion of the circuit is thoroughly insulated, and with a view of providing perfect immunity from fire every lamp in the building is provided with a cut out. In the warping room the lamps, by a special fitting, are allowed to travel to and fro with the warping machines, and can also be used in any position or at any angle. Special notice must be made of the very handsome and massive main switch-board which Messrs. Fletcher and Co. have made and fitted in the engine room. Four heavy polished brass switches with their fusible plugs control the four main circuits, and are mounted upon a polished slate slab 3½ft. by 2½ft. in size, the slab, in turn, being set in a handsome moulding. The main cables leading to and from the switch-board are also enclosed in ornamental mouldings; and the whole apparatus forms a very ornate adjunct to the installation. It is noteworthy that the whole of this work has been manufactured in Dunedin, as indeed have all the necessary fittings and plant, save and except the dynamo, the lamps, and the wires. In addition to the lighting, Messrs. Fletcher and Co. had fitted up an electro-motor of about four indicated horse-power. This was actuated by the current from the lighting dynamo, and was used to drive the hydro-extractor in the milling room. The electrical transmission of power has an undoubtedly important future before it in the colony; and we understand that the major portion of Messrs. Fletcher and Co.'s business is already in this direction, rather than in lighting contract for the transmission of over thirty horse-power, a distance of four miles being now in course of execution, and arrangements are also being made by which the Dunedin tram cars will be propelled by electricity instead of being drawn by horses. After a thorough inspection of the buildings, machinery, and electric apparatus had been made, the company repaired to one of the rooms, where light refreshments had been provided.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 7.)

Normal Electromagnetic Systems. Energy Conjugate Properties.

The specification of the complete state of the electromagnetic field at a given moment requires a knowledge of seven quantities. We must, in the first place, know the electric capacity and conductivity, and the magnetic permeability, c, k, and μ. Next, we require to know the electric and the magnetic force, E and H. From these five data we know, by the linear relations, the conduction current $C = kE$, the elastic displacement $D = cE/4\pi$, and the magnetic induction $B = \mu H$. We also know the electric energy $\frac{1}{2}ED$, the magnetic energy $\frac{1}{2}HB/4\pi$ and the dissipativity EC; all per unit volume. But, in addition, we require to have given the impressed electric and magnetic forces, e and h. Then, by the two equations of induction,

$$\left.\begin{aligned} \text{curl}.(H - h) &= 4\pi\Gamma = 4\pi(C + \dot{D}) \\ \text{curl}\,(e - E) &= 4\pi G = \dot{B} \end{aligned}\right\}$$

we know the true electric current Γ, and therefore the displacement current $\dot{D}$; and also the magnetic current G. As for the electrification, it is known because D is known, of which it is the divergence. The seven data may be otherwise stated; for instance, instead of E and H, we may have D and B, or C and B. As regards the number of distinct numbers on which these seven quantities depend, if we take any three rectangular axes of reference, the four vectors E, H, e, and h require three numbers each, making twelve, and the three operators c, k, and μ require three numbers each (if there be no rotatory k), making eighteen. Thus altogether thirty numbers are concerned; or thirty-three, if there be rotatory conductivity. In case of isotropy, the number is fifteen, owing to c, k, and μ being then simply scalars.

We not only know the complete state of the system, but the rate at which it is changing; for $\dot{E}$ and $\dot{H}$ are known, and therefore, if the impressed forces be given at every moment, we can find the changes it goes through under their influence; or, if they be absent, in settling down to a state of equilibrium.

The equation of activity at any moment is

$$\Sigma e\Gamma + \Sigma hG = Q + \dot{U} + \dot{T};$$

the left member being the total activity of the impressed forces in all space, and the right its equivalent, the sum of the dissipativity Q (Joule heat per second) and the rates of increase of the electric and magnetic energies.

Now, suppose no relative motion of masses is permitted, thus making c, k, μ functions of position only, and excluding the impressed forces brought into play by such motions. If now e and h be constant with respect to the time, the system will settle down to a steady state, in which $\Sigma eC = Q$ simply. If, further, there be no e in conductors, or, more generally, only such distributions as may cause elastic displacement, but no steady conduction current, the final field is simply that due to h and to the e left, and to electrification and its surface equivalent, the charges of conductors.

But, by the linearity of equations, the inductive phenomena during the subsidence to the final state under the influence of steady e and h may be got by superimposition. We may therefore, in investigating subsidence, take $e = 0$, $h = 0$, and no electrification or charges on conductors; so that the subsidence is to a final state of no E or H anywhere.

We then have, at every moment after removal of impressed forces,

$$Q + \dot{U} + \dot{T} = 0; \quad \ldots \ldots \quad (100)$$

the rate of decrease of the sum of the electric and magnetic energies being equal to the dissipativity. Q, U, and T are all necessarily positive, being sums of squares, or else of positive scalar products. (For instance $EC = EkE$; if C is parallel to E, it is a square kE^2; if not parallel, their mutual angle must be always acute). This necessary positivity is of the greatest importance, as it excludes the possibility of indefinite increase of normal systems of force left to themselves, making them always subsides either without or with oscillations.

Let next there be two systems of electric and magnetic force distinguished by the suffixes $_1$ and $_2$, so that their equations of induction are

$$\text{curl}.H_1 = 4\pi\Gamma_1; \quad -\text{curl}.E_1 = 4\pi G_1; \quad \text{curl}.H_2 = 4\pi\Gamma_2; \quad -\text{curl}.E_2 = 4\pi G_2.$$

Using the third and second of these, we find by space integration,

$$\Sigma E_1\Gamma_2 = \Sigma E_1\text{curl}.H_2/4\pi = \Sigma H_2\text{curl}.E_1/4\pi = -\Sigma H_2G_1.$$

Similarly, by the first and fourth, we shall get $\Sigma E_2\Gamma_1 = -\Sigma H_1G_2$; so that we have

$$\Sigma(E_1\Gamma_2 + H_2G_1) = 0, \text{ and } \Sigma(E_2\Gamma_1 + H_1G_2) = 0;$$

or,

$$\left.\begin{aligned} \Sigma E_1C_2 + \Sigma E_1\dot{D}_2 + \Sigma H_2\dot{B}_1/4\pi = 0, \\ \Sigma E_2C_1 + \Sigma E_2\dot{D}_1 + \Sigma H_1\dot{B}_2/4\pi = 0. \end{aligned}\right\} \quad . \quad . \quad (101)$$

If we add these, we shall obtain

$$Q_{12} + \dot{U}_{12} + \dot{T}_{12} = 0, \quad . \quad . \quad . \quad . \quad (102)$$

the equation of mutual activity. U_{12} and T_{12} are the mutual electric and magnetic energies, and Q_{12} the mutual dissipativity, or the excess of the total dissipativity when the two fields coexist over the sum of the separate dissipativities.

Let next the arrangement of E and H be such that in subsiding they change in magnitude only, not in distribution. Let E_0 and H_0 be the distributions at time $t = 0$, and at time t,

$$E = E_0\epsilon^{nt}, \quad H = H_0\epsilon^{nt}, \quad . \quad . \quad . \quad . \quad (103)$$

The constant n is the reciprocal of a time, and is of course negative, if the subsidence be real. The larger n the more rapid the subsidence. E and H thus defined constitute a normal system of electric and magnetic force.

Now,

$$\left.\begin{aligned} Q = \Sigma EkE, \quad & U = \Sigma EcE/8\pi, \quad & T = \Sigma H\mu H/8\pi, \\ = Q_0\epsilon^{2nt}, \quad & = U_0\epsilon^{2nt}, \quad & = T_0\epsilon^{2nt}, \end{aligned}\right\}$$

by (103), if Q_0, U_0, T_0, be the initial values. From this, $\dot{T} = 2nT$, and $\dot{U} = 2nU$, which makes the equation of activity (100) become $Q + 2n(U + T) = 0$; or the ratio of the energy left at any moment to its rate of leaving is constant, $= -2n$.

If then the two systems to which equations (101) refer be both normal, with rates of subsidence n_1 and n_2, we shall have

$$\left.\begin{aligned} Q_1 + 2n_1(U_1 + T_1) = 0, \\ \text{and} \quad Q_2 + 2n_2(U_2 + T_2) = 0, \end{aligned}\right\} \quad . \quad . \quad . \quad (104)$$

when they exist separately; and, in addition, when they coexist, the equations (101), in which $\frac{d}{dt} = n_1$ or n_2, according to whether it operates on the first or second system. Now $E_1D_2 = E_2D_1$, $H_1B_2 = H_2B_1$, and lastly $E_1C_2 = E_2C_1$ if there be no rotatory conductivity coefficient; so that (101) becomes

$$\left.\begin{aligned} \tfrac{1}{2}Q_{12} + n_2U_{12} + n_1T_{12} = 0, \\ \tfrac{1}{2}Q_{12} + n_1U_{12} + n_2T_{12} = 0, \end{aligned}\right\} \quad . \quad . \quad . \quad (105)$$

where $Q_{12} = 2\Sigma E_1C_2$; $U_{12} = \Sigma E_1D_2$; $T_{12} = \Sigma H_1B_2/4\pi$.

Between the equations (105) we may eliminate in succession either the Q, or U, or T. Thus we get, if we leave out the common factor $(n_1 - n_2)$,

$$\left.\begin{aligned} 0 &= U_{12} - T_{12}, \\ 0 &= \tfrac{1}{2}Q_{12} + (n_1 + n_2)T_{12}, \\ 0 &= \tfrac{1}{2}Q_{12} + (n_1 + n_2)U_{12}, \end{aligned}\right\} \quad . \quad . \quad . \quad (106)$$

which are the universal conjugate properties of normal systems.

The first tells us that the mutual potential and kinetic energies of two normal systems are equal. This being true at every moment during the subsidence, it follows, by (102), that the mutual dissipativity is derived from them equally. This is the interpretation of the second and third of (106), the second saying that the mutual dissipativity equals twice the rate of decrease of the mutual kinetic energy, and the third that it equals twice the rate of decrease of the mutual potential energy.

Any one of (106) enables us to decompose a given initial state of electric and magnetic force into the sum of normal

Digitized by Google

distributions, when the nature of the latter has been found, and hence determine the manner of subsidence. Thus, let E_0, H_0, be the initial state, and E_1, H_1; E_2, H_2; E_3, H_3, &c., the various normal distributions, with constants n_1, n_2, &c. Let

$$\left.\begin{aligned} E_0 &= A_1E_1 + A_2E_2 + A_3E_3 + \dots \\ H_0 &= A_1H_1 + A_2H_2 + A_3H_3 + \dots \end{aligned}\right\}$$

where the A's are coefficients fixing the absolute magnitudes of the normal solutions. If the A's can be found, then, at time t later, we shall have

$$E = A_1E_1\epsilon^{n_1t} + A_2E_2\epsilon^{n_2t} + \dots ;$$

E being what E_0 then becomes; and a similar equation for H.

The A's are found thus :—E_0 and H_0 being given, and the rth coefficient A_r being required, calculate the mutual potential and the mutual kinetic energy of the given state with respect to the rth normal distribution. Let them be U_{or} and T_{or}. Their values are

$$\begin{aligned} U_{or} &= A_1U_{1r} + A_2U_{2r} + A_3U_{3r} + \dots + A_rU_{rr} + \dots, \\ T_{or} &= A_1T_{1r} + A_2T_{2r} + A_3T_{3r} + \dots + A_rT_{rr} + \dots . \end{aligned}$$

Subtract the second line from the first, and there results

$$U_{or} - T_{or} = A_r(U_{rr} - T_{rr}); \text{ or, } A_r = (U_{or} - T_{or})/(U_{rr} - T_{rr}), \quad (107)_1$$

since, by the first of (106), all the remaining terms cancel. Thus, the rth coefficient equals the excess of the mutual potential over the mutual kinetic energy of the given state and the rth normal state, divided by twice the excess of the potential over the kinetic energy of the normal state itself.

The second and third of (106) give two equivalent relations, by widely different processes, viz.,

$$A_r = (Q_{or} + 4nT_{or})/(Q_{rr} + 4nT_{rr}), \quad . \quad . \quad (107)_2$$

and

$$A_r = (Q_{or} + 4nU_{or})/(Q_{rr} + 4nU_{rr}), \quad . \quad . \quad (107)_3$$

As the first of (106) is the easiest to remember, so it is in general the most readily applied, giving $(107)_1$. But some special cases should be noticed.

If there be no potential energy, but only kinetic energy and dissipativity; that is, in all problems in which dielectric displacement is not taken into account, as, for instance, any combination of conductors between which there is electromagnetic induction, but with no condensers, we have

$$c = 0,\ T_{12} = 0,\ Q_{12} = 0; \text{ and } A_r = T_{or}/T_{rr} = Q_{or}/Q_{rr}. \quad . \quad (108)_1$$

If there be no kinetic energy, but only potential energy and dissipativity; that is, in all cases in which electromagnetic induction is ignorable, as in any combination of conductors and condensers, but not coils, we have

$$\mu = 0,\ U_{12} = 0,\ Q_{12} = 0; \text{ and } A_r = U_{or}/U_{rr} = Q_{or}/Q_{rr} \quad . \quad (108)_2$$

If there be potential and kinetic energy, but no dis ipation,

$$k = 0,\ U_{12} = T_{12}; \text{ and } A_r = \frac{U_{or} - T_{or}}{U_{rr} - T_{rr}} \quad . \quad . \quad (108)_3$$

In this last case conductors are excluded. We have a strictly conservative system, from which all radical friction is excluded. It goes on oscillating for ever, but never does any useful work. We must therefore abolish it. A peculiarity connected with $(108)_3$ will be noticed in the next section. Also that the general properties (106) are true whether the rates of subsidence of the two systems be unequal or equal, although in the latter case special procedure is required.

The nature of the normal distributions themselves depends upon the distribution of c, k, and μ throughout space. We have

$$\text{curl}\,.\,H = (4\pi k + cn)E\,; \quad -\text{curl}\,.\,E = \mu nH\,; \quad . \quad (109)$$

in a normal arrangement. Hence, either E or H being found, the other follows. Thus, eliminate H to get the equation of E,

$$\text{curl}\ \mu^{-1}\text{curl}\,.\,E + n(4\pi k + n)E = 0 \quad . \quad . \quad (110)$$

Any solution of this is a normal E, and the corresponding H is definitely fixed by the second of (109). Not counting the simple cases of linear circuits and similar problems, (110) has been solved in three dimensions in a very few cases.

Presuming we have obtained the normal solutions, the question arises, what values of n shall we take? We must take all that satisfy all the conditions of the problem. One form of the determinantal equation, whose roots give all the admissible values of n, is the equation of activity itself,

$$Q + \dot{U} + \dot{T} = 0\,; \text{ or, } Q + 2n(U + T) = 0,$$

applied to the normal solutions. It is an equation in n only, with various constants, but independent of x, y, z, and t. That is, if in some special case of (110), we know the normal solution, we can find the equation of n by writing out the equation of activity extended over the whole system. But the equation of n is usually to be obtained from the boundary conditions, when the normal functions are known through bounded spaces.

If we extend our calculation of the excess of the mutual potential over the mutual kinetic energy of two normal systems through a bounded space, instead of all space, we shall obtain, not $U_{12} - T_{12} = 0$, but

$$(n_1 - n_2)(U_{12} - T_{12}) = \Sigma N(VE_2H_1 - VE_1H_2) \quad . \quad (111)$$

the summation being over the boundary, N being the unit normal drawn inward. Hence $U - T$ for a single normal system n is given by

$$U - T = \Sigma N\left(VH\frac{dE}{dn} - VE\frac{dH}{dn}\right). \quad . \quad (112)$$

There are of course corresponding boundary forms for the second and third of (106).

The general properties of normal systems (100), (102), (104), (106), (107), and (108), are not peculiar to the special dynamical connections which are involved in the electromagnetic equations, but belong to any dynamical system in which forces of reaction are proportional to displacements, and resistances to velocities, with reciprocal relations amongst the coefficients which are equivalent (in the electromagnetic case) to the three linear relations between forces and fluxes being of a symmetrical nature; or c, k and μ self conjugate, with no rotatory power. Conservation of energy requires this to be true for c and μ; and (106) are not true unless k be also self conjugate. But further remarks on normal systems must be postponed.

(To be continued.)

THE STEAM ENGINE INDICATOR.—X.*

BY AMICE.

Before proceeding to the condensing engine diagram, we will here give one from a higher type of high pressure non-condensing and, for the stroke, high speed engine, namely,

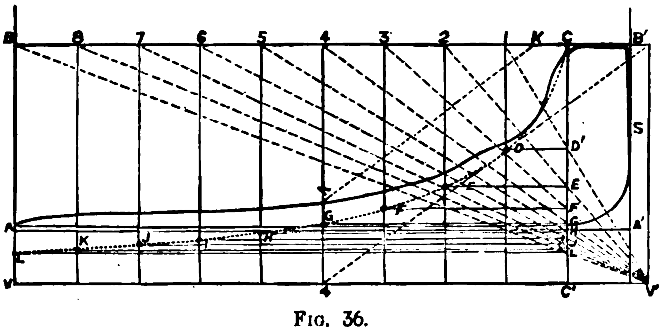

Fig. 36.

an Allen engine. It is given in this place merely to show the form of diagram which results from long range expansion, or, in other words, an early cut off. Fig. 36 is from an engine with an 8in. cylinder, area = 50·26, stroke 2ft., revolutions 150 per minute, and steam cut off at one tenth of the stroke, giving a ratio of expansion of ten. The engine was running light at the time the diagram was taken with a Richards indicator, and the back pressure, which is shown by the space between the lower line of the diagram and the atmospheric line A A′, was caused by the long length of exhaust pipe which was attached to the engine, aggravated by several bends. We have drawn an enclosing parallelogram about the diagram for the purpose of explanations, to which we shall recur later on. It will be seen that the steam admission line S departs from the vertical above S, showing that the full pressure was not realised until the piston had moved about a quarter

* For Art. 9, see *The Electrician*, 20th November, 1885.

Digitized by Google

of an inch, the admission being somewhat restricted, there being practically no lead. At C the cut off took place, that is at the end of the first tenth of the stroke, and the pressure fell to one-half the maximum when the next tenth of the stroke was completed. From thence it falls gradually, until at the end of the stroke the pressure was 4·25lb. Exhaust then took place, but the pressure did not drop below 2·25lb., until the piston had made a considerable part of its return stroke, and never much below 2lb. At G the exhaust port is closed, and compression commenced. The valve gear of this engine is of a very quick acting kind, and cut off takes place without wire drawing. It will be remarked that the curve falls just above the letter D, forming a hollow curve. Between the division lines 1 and 2 the curve becomes convex, and afterwards again assumes the proper hollow expansion curve. The wavy line between or within the second and third divisions is caused by the oscillation of the indicator spring, and the inertia of the attached parts, both being brought into play by the sudden falls of pressure and correspondingly sudden movement of the indicator piston. There are other causes assumed to act to bring about this wave line, which is often much more pronounced than is here shown from an engine running at 150 revolutions per minute. We have not written upon this diagram the various pressures, as these figures would have confused an already filled diagram, but a measurement gives a mean pressure of 14·2lb. per square inch, the maximum pressure being 50lb. The piston rod being 1·75in. diameter gives an area of 2·4 square inches. As the rod only passed through one cover, we have to deduct only half this area from that of the piston, bringing it down from 50·26 to 49·06, or, say, 49 square inches. The indicated power of this engine was thus $\frac{49 \times 2 \times 150 \times 2 \times 14{\cdot}2}{33{,}000} = 12{\cdot}78$ horse-power.

Or we may simplify the figures by taking the piston speed in feet per minute and the power per lb. pressure. The piston speed being 600, we have $\frac{600 \times 49}{33{,}000} = 0{\cdot}899$, or, say, 0·9. The indicated power at the above pressure is then $14{\cdot}2 \times {\cdot}9 = 12{\cdot}78$.

We have drawn upon this diagram the theoretical curve of expansion according to Boyle's or Marriotte's law. It should, perhaps, be always called Boyle's law, as by him it was discovered in 1662, and afterwards verified by Marriotte, and is to the effect that the pressure of a gas at constant temperature varies inversely, as the volume of the space it occupies—that is to say that if p and v represent pressure and volume, then $p\,v =$ a constant. This is true for gases such as air, but it is not true for steam; but upon this assumption this so-called theoretic curve is drawn, and is very valuable for purpose of comparison. The curve is hyperbolic, and in practice is very nearly approached in consequence of conditions which come into play when steam is used to perform work expansively in a cylinder, as will be explained. For the present we may notice that our diagram shows pressures which from the middle of the second tenth part of the stroke are greater than the hyperbolic curve demands when the cut off is at C. This is in consequence of the re-evaporation of a very large quantity of steam, which is condensed in the first part of the stroke on its entrance into a cylinder cooled down to the temperature of steam at the end of the previous stroke, at about 4lb. The absolute pressure, as shown by the above diagram, at the end of the stroke, is 19lb., corresponding to a temperature of 225deg.; the temperature at the commencement of the stroke is that corresponding to a pressure of 76lb. absolute, or 308deg., the range of temperature being 83 degs.; but if the heat of the steam condensed in the commencement of the stroke did not provide the means of re-evaporation of the water in the cylinder, and of maintaining the temperature throughout the stroke, the pressure would fall at least as low as shown by the hyperbolic or isothermal curve in diagram 36, or to as low as 7lb.—really it would fall much lower. The temperature due to 7lb. pressure is 177 deg., or a range of 131 degs. The lowering of temperature of the cylinder consequent upon this range of temperature calls for the condensation of a large quantity of steam during the commencement of every stroke, and this being re-evaporated during the later part of the stroke under the falling pressure of temperature gives the steam pressure which keeps the indicator diagram high above the hyperbolic curve. Before leaving this diagram it may be pointed out that during a large part of the stroke the pressure is not sufficient to overcome engine friction, so that for this reason alone, apart from others of equal importance, it is clear that a range of expansion of ten is not an economical one.

Leaving this high-pressure non-condensing engine diagram for the present, we must turn to typical diagrams from high-pressure condensing engines as distinguished from the low-pressure condensing engine diagrams (Figs. 33 and 34) taken from the atmospheric engine referred to at page 11.

First, we must deal with the diagrams from a Cornish engine. Not because these are often met with now, and at any time only as pumping engines, but because the Cornish engine diagram is peculiar; and our articles would be incomplete without a brief reference to this, the most important, form of single acting condensing engine. It must be premised that the steam only does direct work in the down stroke of these engines and on the top of the piston; but indirectly it does work by condensation on the lower side of the piston. The weight of the pump rods and buckets is sufficient to pull the engine beam down at the pump end, and, of course, up at the engine piston end. No steam is thus directly required to raise the piston. The working of the engine is as follows:—Steam is admitted to the top of the piston, and is cut off earlier or later according to the load; when the piston is at the bottom of the stroke a valve affording communication between the two ends of the cylinder, and called the equilibrium valve, is opened,

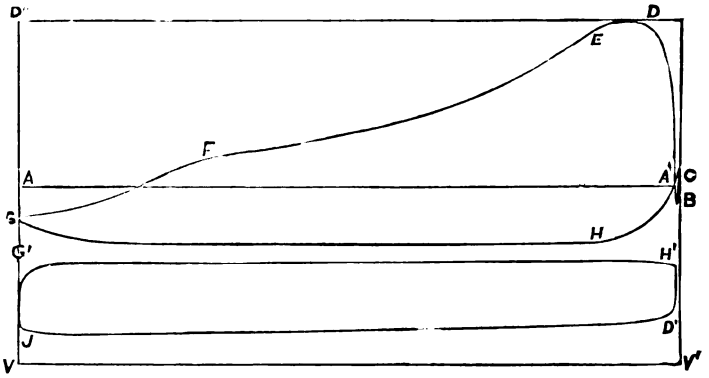

FIG. 37.

and the steam from the top of the cylinder is thus free to pass to the bottom. Equilibrium is thus established between the top and the bottom of the piston, and the piston is lifted by the beam, all the steam passing to the under side of the piston as it leaves the upper, and the pressure falling somewhat. When the piston is at the top of the stroke the equilibrium valve is closed, and a valve communicating between the lower side of the piston and the condenser is opened, the steam is condensed, and a vacuum formed. At the same time the steam valve is opened to the top of the piston, and the down stroke is performed by steam pressure at the top of the piston and by vacuum beneath it, or by atmospheric pressure added to the steam pressure acting on the top of the piston. The diagram obtained from such an engine is given in Fig. 37. In this diagram, which is given full size as taken, the scale being one-sixteenth inch to the inch, A A′ is the atmospheric pressure line, V V′ the line of absolute vacuum. Tracing the pencil we may follow the piston in its downward stroke. Steam is admitted and the pencil rises from A A′ to D, one-twentieth part of the stroke being performed before the maximum pressure is reached, owing to a somewhat restricted steam passage or slow valve. The piston descends, steam is cut off at somewhere near E, and expands down to F, when the equilibrium valve begins to open, and the pressure falls to G. At this point the equilibrium valve is full open and the piston begins to rise, the steam passing from above it to below it as it does so, and the line G H is traced from the top of the cylinder, while the line G′ H′ is traced from the lower end, the gap between the two lines representing loss of pressure in the communications between the two ends of the cylinder. When the

Digitized by Google

piston reaches the top of the stroke, not only is steam admitted, as before, to the top of the piston, but the exhaust valve opens and the steam from below rushes into the condenser, and the pencil falls from H′ to D′. The down stroke is now made under the pressure H D + H′ D′, and (with an indicator at either end of the cylinder) the lines A′ D E F G and D′ I are simultaneously drawn. It will be noticed that in the up-stroke the equilibrium valve closes at H before the stroke is completed, and the steam imprisoned on the top of the cylinder is compressed, as shown by the curve H C. The compression increases the pressure, and carries the pencil to C, but as soon as the piston stops, loss of heat by conduction, radiation, and leakage causes the fall of pressure again to B before the new steam enters, and hence the loop C B. When pressure has fallen to B, new steam enters, and the pencil rises as before to D, and the operations recommence.

Our space compels us to leave the high-pressure, double-acting, or ordinary condensing engine diagram until next week.

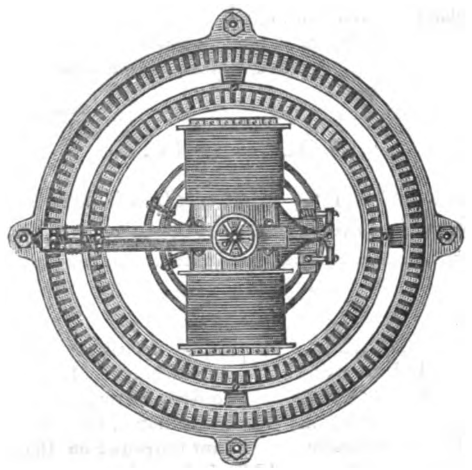
ELECTRIC HAULAGE.

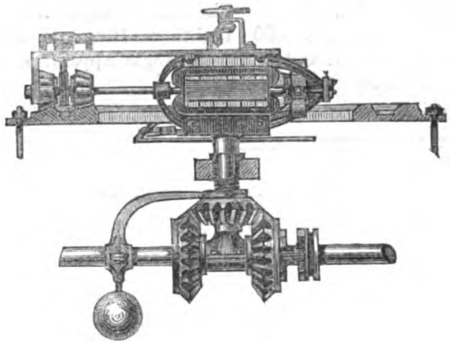
Within the last few years, almost within the last few months, we have had many schemes of electric locomotion before us, some of them depending upon the practical transmission of electrical energy over short distances, while others have been the outcome of comparatively recent improvements in storage batteries. In the majority of cases this new method has been applied either to the propulsion of launches or other small boats or to the haulage of tram cars, and in this latter direction some degree of commercial efficiency has been arrived at. As regards the merits of the various ways in which the current is conveyed in each case to the electro-motor opinions differ. Direct driving—the rails being in the dynamo circuit—has its disadvantages during very wet weather, for there *must* be an appreciable loss, however carefully the insulation of the line is attended to; the overhead conductor is a nuisance, and the use of accumulators—a method which seems to us to bear the greatest promise—is restricted, or, rather, delayed by the unfortunate fact that the accumulator is but ill adapted for the purposes to which it is applied. In other words, speaking from a commercial point of view, the storage battery must undergo radical alteration before any decided advance is made in the direction of electric locomotion. It is always interesting, however, to learn that a step forward has been made by any one of the many workers in this field, and the chronicling of such an event is a task which to us is always a grateful one.

Within the last few days we have been enabled by the courtesy of the Electric Locomotive and Power Company to inspect a new tram engine now being experimentally used at the North Metropolitan Tramway Company's depôt at Stratford. This engine has been contrived by Mr. C. P. Elieson, and is one of the happiest combinations of electrical and mechanical power that we have seen. It is novel and yet it is not novel—a paradox and an excellent invention. The novelty consists of the mode in which the power is transmitted to the driving axle—in the fact that the motor itself revolves, and in the substitution of a mechanical clutch for the electrical reversing gear hitherto adopted. The want of novelty is present in the motor, which is of ordinary construction, with a link armature; and in the secondary cells, of which there are 50 (E.P.S.), giving 280 ampere hours and rather over 100 volts. The mechanical connection of the motor is very ingenious, in that Mr. Elieson has done what we may fairly suppose that Archimedes would have done had he lived in these days of enlightenment. He has applied a lever between the electro-motor and the axle of the locomotive in such a way that the motor, which must necessarily run at a high rate of speed in order to develop the greatest efficiency, acts through the lever by a method analogous to the case of a man using a crowbar for the purpose of lifting a heavy weight. By this contrivance the *vis inertia* of the loaded tram car is easily overcome, and it is evident, even to non-scientific readers, that speed is then easily attained until the natural speed of the electro-motor is approached by the rate of speed of the driving wheels.

Instead of the electro-motor being a fixture, and having motion transmitted from it through belt or crank gearing to the wheels of the car—a method which involves loss of power, and necessitates the provision of ample space—the motor itself revolves, the motion being transmitted through bevel gearing. It has, as will be seen by our illustration, a vertical shaft through its centre, to which a motion lever projecting horizontally about 2ft., and carrying at its outer end a spur-wheel gearing into a fixed circular rack, is secured. This vertical shaft carries at its lower end a bevel wheel, which gears into one or other of two similar wheels on the driving-axle of the engine. The mitre gearing is equipped with a mechanical clutch, by means of which the engine may be made to run either backwards or forwards; a lever, acting mechanically, throwing the motor in or out of gear, or adjusting the clutch by a simple movement of the hand. This suggests itself to us as being a very good arrangement indeed. In the first place there is a minimum loss of energy, in that the motion being applied direct to the axle there is very little energy wasted in friction, &c.; in the second place the motor, always travel-

Plan.





Elevation.

ling in the same direction, and being above the floor level of the car, it is subject to fewer strains and fewer losses than is the case when reversals are made and when the motor is placed below the floor level, and therefore during wet weather in nearer proximity to a source of leakage; and, in the third place, there is due to the lever a decided gain of power at the moment when it is most wanted, *i.e.*, at starting. The electrical details are very simple. The motor is fitted with collecting brushes travelling on two fixed circular rings of copper, separated from each other by a flange. The speed of the motor is varied by inserting resistances in the ordinary way, and it is evident that great care has been exercised to avoid anything like complexity. The locomotive in appearance resembles a small car, and weighs 4 tons 17cwt. The motor, which is of four horse-power, consumes about 40 amperes per hour, so that it carries power sufficient for seven, say six, hours of motion, and makes about 700 revolutions per minute when in full swing, or a maximum of 1,000 on a level road. The speed obtained is eight miles per hour, it being for certain obvious reasons not desirable to exceed this rate.

THE SOCIETY OF TELEGRAPH-ENGINEERS.

After each recurring annual meeting of this Society for several years past we have thought it right to comment upon the manner in which its election of officers has been conducted. At first we tried protest, then argument, and lastly ridicule. No impression that we know of has been made by any of these methods. This year, therefore, we propose trying another, namely, to say what we have to say beforehand, so that there may be no excuse for acting through inadvertence or forgetfulness. One of our complaints has been that the Society does not notify to its members that the election of its Council is impending in time for them to offer any candidate of their own, or to consider the merits of the nominees submitted for their approval. We will supply this defect on the present occasion, by reminding our readers who are members and associates of the Society that the annual meeting is fixed for the 10th December, when the election, as it is called, of the Council for the ensuing year will take place. If precedent is followed, there will be no notification of this fact from the official source until a few days prior to the event; and as regards the persons to be elected, their names will be posted on the day of the election, or possibly the day before. The form on which this information is conveyed will contain just the number of persons to be elected and no more, and just the names preferred by the Council and no other. If any different course is pursued on the present occasion we shall be glad to give the Council all the credit of it. They have taken so little notice of our complaints hitherto, that anything they may do now, good or bad, will of course be due to themselves, not to us.

In truth we address ourselves now to the electors rather than the Council or the Council's candidates. From members and associates, who, for the subject in hand, are nominally the elective body of the Society, we have frequently heard disparaging remarks on the conduct of the election—remarks much stronger than any we have ever yet used in regard to it ourselves; and we confess to symathising with their complaints to some extent, and entirely condole with them on the ridiculous figure they are required to cut on the occasion of the so-called Balloting. The Ballot Box ought to tell the same tale. If our own eyes have not deceived us the number of papers deposited in the sacred urn have grown fewer and fewer every year; and none but innocent young men, or casehardened old ones, now think it worth while to make the solemn journey, paper in hand, down the gangways in order to ratify a conclusion which has been already settled elsewhere. It must be as hard for the Council to keep their countenance while this empty function is being enacted as it is for the electors to keep their temper. We hear just now a good deal about voting for the "ticket;" but we never heard of the wires being pulled by any political or scientific caucus when there was positively no opposition. Here the ticket is drawn up and the wires pulled, just as if the "will of the nation"—or, rather, the wishes of the members—were being consulted and weighed in real earnest. And when this formal make-believe is repeated year after year it does not surprise us that some of the spectators get impatient, and begin to ask whether it would not be better to dispense with the formality altogether, seeing that its retention is a waste of time at the best, and at its worst perpetuates the fiction that members and associates of the Society have a voice in the selection of its governing body.

Our own view, however, is not that the ceremony should be done away with, but that it should be made into a reality; or, at all events, that the event should be arranged so as to shift the unreality to the members themselves. At present the conduct of the whole business from beginning to end has the appearance of superseding the choice of the members and taking pains to hinder its exercise. We say it has this appearance; and quite needlessly we think. The power of exercising their privilege ought to be retained by the Society as a body, for it might be useful some day. But if events have proved that the right is seldom or never used, there is all the less reason for the Council to delay their nominations, or to forbear apprising the members of their rights in due time. The "ticket" of the Council is uniformly accepted; it generally would be accepted even if ample time were given to challenge it. But something more than this might be done; surely it is not impossible to select and submit more names than are actually required. This, whenever practicable, would relieve the Council of the imputation of dictating a hard and fast programme, which cannot be disputed without virtually passing a vote of censure on the framers, which no one wishes to do.

No doubt there are difficulties—some practical, some sentimental—which members are not perhaps so well aware of as they might be. It is well that the governing body should maintain its continuity by electing only men who will be likely to work with them on the same lines, men who will do credit to the Society, and who, in their turn, if otherwise eligible, will fill the positions of President, or Vice-President, with dignity and understanding. The haphazard choice of the members

Digitized by Google

might conceivably fall upon a wrong man; but it would be the fault of the Council if it did. It is not their fault, however, that eligible candidates refuse to be nominated if they are to be subject to the risks of an election. The risk, as we have already hinted, is very small, or may be rendered so; but if a distinction is to be conferred it is none the worse for being given by vote, and the man who will not face it is not wholly deserving of it. We think this would be the general opinion of the elective body; aud it would do the weak-kneed gentlemen who decline a popular test of this very mild sort no harm to be informed of the fact. Still, no doubt the difficulty is in some instances a real one, and every allowance should be made for the delicate position in which the Council is occasionally placed. What we would urge upon it is, not to yield to the prejudice or the pride—whichever it may be—of these scientific top sawyers too readily; and, above all, not to be tempted into a false position with the Society as a whole in order to secure the services or spare the susceptibilities of any one man. It is right and proper that the Council recommend their successors in office; but whenever practicable they should leave some choice of selection for the members, and in any case should make a decent show of affording opportunity for them to exercise their undoubted right to nominate, if they are so minded. There would be time enough to correct it if any harm were threatened under such a system—which, however, is not at all likely.

CORRESPONDENCE.

THE SOUDAN CAMPAIGN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am much interested in the account of the use of the telephone for military telegraphing by Major-General Webber, and your remarks on this point in your leader.

I have been engaged in devising a regimental telegraph plant for the Queen's Edinburgh Rifle Volunteers Brigade, which I command, and propose to use the telephone both as transmitter and receiver. When transmitting in the field the telegraphist will rub the mouth of his telephone round and round on a roughened disc hanging from his belt at the left side, and make and break contact by a commutator attached to his belt at his right hand, thus producing the Morse symbols. Mr. Preece and Prof. Blyth are kindly making experiments for me to test the feasibility of the suggestion. There can be no doubt that it would be a great gain in field telegraphy if we could get rid of all cumbrous batteries with their weight and bulk, and their liquids and chemicals, which climate and accidents so easily injure. But there is a further and military advantage by which I set great store, viz., enabling each battalion to carry its own telegraph appliances without horse transport. This would be a great advantage, as the present system of a separate telegraph corps, working with heavy waggons, is most unsatisfactory. It necessitates the telegraph plant for large bodies of troops being concentrated in great quantities, and the laying out of it being not done in sections, but in a long line. This is inconsistent with rapid laying and rapid picking up. Besides, it prevents all use of the telegraph for sectional purposes, if I may use the term. Would it not be a most useful thing if regiments sent on outpost duty could run out a line from their main body to their advanced posts, and thus communicate freely and rapidly? Besides, in modern war it is very important to have telegraphists as part of the interior economy of the smaller units of the service. At any moment in war the presence of a telegraphist may be useful. Such a measure as tapping an enemy's wire, if you come on it, can only be done if you have a telegraphist available. But last and not least, can it be doubted that the presence of telegraphists with each battalion would greatly facilitate the establishment of communication at the end of the day's march of an army? Each battalion would at once lay its cable along its rear, coupling on to the next, and thus in a few minutes whole brigades and divisions would be in communication, where under the present system the telegraph corps might take hours before they could run out their cable from its four-horse waggon.—Yours, &c.,

Edinburgh, Nov. 21st, 1885. J. H. A. MACDONALD.

A PHENOMENON OF CURRENT INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The experiment described (p. 35) by "An Electrical Student" is interesting, and resembles, in principle, one which I think has been described by Prof. Forbes. The results are in exact accordance with what I should expect upon the principles I laid down Nov. 6th, p. 485, Vol. XV. It may be well to explain this, because I there said that I should expect the closing of the secondary circuit to *reduce* the primary current, while these experiments show that it was increased. The reason of this apparent contradiction is that I was reasoning about the action with a current, *intermittent, but always in one direction*, while the experiments were made with an *alternating current*. Now, my principles would result in a diminished primary current with an intermittent but uniform E.M.F., and in an increased primary current with alternating E.M.F., as a consequence of closing the secondary circuit.

The same principle gives the opposite results, viz., that work has to be done in the secondary wire in producing the current.

With a merely intermittent current the E.M.F. generated in the wires, primary and secondary, at the moment of break is in the same direction as that of the generator; therefore, anything which prolongs that current and prevents the complete loss of the magnetism of the core is a help to the incoming primary current, or in other words diminishes the call upon it for fresh energy to re-magnetise the core. Closing the secondary circuit facilitates the de-magnetisation, therefore is work put upon the E.M.F., and reduces the current in the primary.

But with an alternating current any such residual energy, current, or magnetism *opposes the next entering current*. Hence we find that the introduction of a coil of wire in the circuit of generator and lamps reduces the current and light by its so-called "self-induction," and increasingly so when the core is inserted. In fact, at each alternation the current has to expend energy, not only in remagnetising the core, but also in driving out an opposing magnetism, so that the E.M.F. of the generator meets a counter E.M.F. in the coil.

Now, if the secondary circuit is closed, an outlet is at once provided for this reverse E.M.F.; it can do work in the secondary. Of course this work is taken from the primary circuit, the current of which is therefore reduced from what it would be if the coil were absent, but greater than it would be with the coil present and the secondary ciruict open—in fact, we may regard the closed secondary as a short circuit for the opposing E.M.F.; but it no longer acts *in the primary circuit* as an opposing E.M F. as well as a resistance. It is got rid of in the secondary wire as a current, and may be utilised, while if the secondary is absent it blocks the primary circuit, and appears as heat in the core and wire of the coil.—Yours, &c.,

J. T. SPRAGUE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The class room experiments mentioned (p. 35) by "An Electrical Student" have, to say the least, a very close connection with the phenomenon which you kindly allowed me to bring forward for discussion, and accordingly I am for my part much indebted to him for the contribution. One's idle self is tempted to think that Mr. Kennedy's results settle the question, but considering that his alternating currents are not precisely the same thing as the intermittent currents at work in my own case, I must accept the duty of experimenting imposed on me by Mr. Sprague. As regards other parts of

Digitized by Google

Mr. Sprague's letter (p. 485, Vol. XV.), I hesitate to deal with his argument at present, as I feel the incompleteness of my own ideas in what I might say to it upon an orthodox basis. I am reading through Mr. Sprague's book, which I have just now added to my library—a very striking work. And while my preparations, mental and manual, are going on, I am very glad that others are interesting themselves in the subject, which one may thus hope to see fully elucidated. May I add that if there are any whose interest shrinks from expressing itself in public print, it will be a privilege to me to hear their opinions by private letter.—Yours, &c.,

E. ALDRED WILLIAMS.

37, Burlington-road, W. Nov. 21, 1885.

HIGH-SPEED ENGINES AT THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In a letter by Messrs. Crompton and Co., published in your last impression, there are the following sentences:—"We ourselves feel the utmost confidence in supplying to our customers dynamo machines driven directly by Willans' engines at speeds not exceeding 550 revolutions. We mention this limit because we think it is only fair that it should here be publicly stated that one of our dynamos, driven by a Willans engine at this speed of 550 revolutions, supplied the current, &c." There is no mistaking the figure. It is 550 revolutions a minute all during the time of the Exhibition, and not a single break down. This is gratifying to the maker of the engine and interesting to a humble student like myself, who is always glad to get reliable information straight from the fountain head. Most of my information on electrical matters I get from your pages; but sometimes I look also to your non-electrical contemporaries for useful data, and then I get sorely puzzled, as in the present instance. For on turning to *The Engineer* of June 26th I find it equally publicly stated that the speed of the Crompton dynamo at the Inventories was 450 revolutions a minute. I know now that the writer of the article in *The Engineer* must have been in error, and it is unfortunate, but excusable, that Messrs. Crompton and Co. did not correct his mistake at the time. I say excusable, because all makers of dynamos are proud of low speeds, and if a gentleman of the press takes it upon himself to make a particular dynamo appear better than it really is by reducing its speed by 100 revolutions, why, it is his business and not that of the maker. I am glad Messrs. Crompton and Co. have by their letter eliminated what scientists call the personal error, but there is still something I cannot understand.

According to *The Engineer*, the dynamo in question has an armature core 12in. in diameter, 28in. long, and contains 120 turns of wire. How is it that this machine required to be driven at the high speed of 550 revolutions a minute, when another dynamo erected at Buckingham Palace, with the same size armature core, but having only 96 turns of wire on it, produced the same electromotive force at only 440 revolutions? Messrs. Crompton, who are the makers of both these machines, will perhaps explain, and thus confer an intellectual benefit on A PUZZLED STUDENT.

LIGHTING WITH PRIMARY BATTERIES.

On Wednesday we witnessed the lighting of several rooms by incandescent lamps which obtained the required current from Ross's primary battery. Mr. Clarke, of 27, Queen's-gate, when fitting up his house was struck with the beauty and the cleanliness, not to mention the healthiness, of the electric light, and he determined to supplement the gas with electricity. The chandeliers in the dining room, drawing room, hall, &c., were modified so that the wires could be taken to incandescent lamps placed alternately with gas lamps. Unfortunately, the designer of the chandeliers is unknown to us, but whoever he is he deserves great credit for the elegant production to be seen at Queen's-gate. The lamps used are 10 candle-power nominal. The current is supplied by four 13-cell Ross batteries kept in the coal cellar. The batteries are connected, two parallel, so that they form two batteries of 26 cells each. Several of the cells were not in use at the time of our visit. A simple arrangement is made for the drawing off the used-up liquid and filling with the active liquid. This work has to be done each day, the quantity of active liquid used to replenish the cells being proportional to the number of hours the lamps have been lighted the preceding night. The exhausted liquid is drawn from all the cells simultaneously by means of glass tubing and flexible rubber connectings. The refilling of the cells is managed by the same apparatus. There has never been any denial as to the possibility of using primary batteries for the electric light, the only question in consideration being that of cost. The manufacturers of this battery, Messrs. Hunter, Harrison, and Co. state that its first cost is low, the cost of working does not exceed, and is in many cases less than that of gas: it requires but little and only unskilled attention; it can be absolutely relied on, and is of course noiseless. The following is the report of Dr. John Hopkinson, F.R.S., on the Ross primary battery:—"Its constancy with a large current is remarkably good; the method of drawing and replenishing the liquids is very convenient. The form in which the carbon electrode is arranged is an advantageous one, and the liquids used in the cells are less expensive than in any battery having any pretence to constancy."

REIS'S ACOUSTICAL TELEPHONE.

(*Continued from page 18.*)

Assuming, for the sake of argument, the correctness of the explanations generally given as to the manner of operation of, say, any of Edison's contact transmitters, the explanation would be as follows, viz.: The sound waves impinging on the diaphragm impart to it vibrations similar, in their movements and complexity, to the vibrations they would also produce in the ear of a person standing near the speaker. The movements so produced in the diaphragm vary the pressure of the contact points and cause corresponding variations in the electrical resistance of the circuit in which the variable-resistance contact points are placed. These variations acting on the magnetic receiver at the receiving end of the circuit, reproduce in its diaphragm the motions of the transmitting diaphragm, so that one listening at the receiving instrument hears whatever sounds are made at the transmitting instrument.

In order to avoid the too great movements of the contact points, by means of which one of them would be thrown completely off from the other, *and thus be prevented from receiving the impress of the movements of the diaphragm while it was separated from it*, one or both of the contact points are mounted on springs, the pressure of which against the other point on the diaphragm is controlled by regulable screws. When properly adjusted, the contact point follows the motions of the diaphragm, and instead of actually leaving it completely and entirely, only leaves it at certain points of its surface, thus varying the cross section of the conducting surfaces in contact, and, of necessity, their electrical resistance.

If it were a matter of indifference whether the contact point occasionally left the diaphragm long enough to prevent it from receiving the impress of all its to-and-fro movements, the regulating screw would be unnecessary. The presence of this screw, when taken in connection with the elastic support of one of the contacts, would appear clearly to show that the inventor intended, when he produced such a mechanical structure, to avoid the too free movement of the contact; that he intended the contact to be influenced by all the movements of the diaphragm; that he desired especially to avoid such a free movement of the contact point as would prevent it from leaving the diaphragm for such a length of time as to cause it to miss some of the to-and-fro movements of the diaphragm.

In the Berliner transmitter, the weight and inertia of the swinging contact permits the suppression of the elastically-mounted contact and its adjusting screw. In the Blake transmitter the elastic support is given to both contacts, their weight and inertia permitting the suppression of the adjusting screw.

Applying the preceding description of the mode of operation of Edison's, Berliner's, and Blake's transmitters to sketches 1, 2, 3, 4, and 5 of Reis's transmitters, we fail, after careful thought, to perceive any differences in their mode of operation. Their

Digitized by Google

mechanical structure and the relative arrangement and proportion of their parts are practically the same. The action of the sound waves on the diaphragm and its action on the contact points are the same, so that, whatever one does, the other does ; whatever one is, the other is.

Now, in considering the only fair and proper meaning to attach to Reis's use of the words "make" and "break," we would call attention to the following important points, viz., that where necessary to prevent such makes and breaks as would be injurious to proper action, we find in all of Reis's transmitters :

1. Elastically-supported contact points.
2. Regulable screws provided for varying as desired the pressure of the contact point against the diaphragm, and that, moreover, when such devices are unnecessary, as No. 5, they are markedly absent.

In view, then, of these facts, clearly shown by the mechanical structure of his apparatus, we find it difficult to understand how any one is willing to maintain that Reis intended that the "makes" and "breaks" he alludes to in his description of the theory of operation of his apparatus were of such a nature as to produce such a free movement of the variable contact point *as would throw it completely off or away from the diaphragm, so as to cause it to lose some of its to and fro movements.* That such was never intended is not only proved by the elastically supported contact and its regulating screw, but also by the direct statements of the inventor. He speaks thus of the contact: "The little hammer-shaped wire *d* being pushed back" at each condensation, which would be clearly impossible if it lost some of the condensations. He asserts that "the movable angle (of his cabinet apparatus) will be lifted up and will thus open the stream at every condensation of air in the box ; the stream will be re-established at every rarefaction."

That Reis could not have intended his use of the words "make" and "break" to signify such a separation of the elastically-supported contact as would remove it from the diaphragm long enough to permit it to miss some of its vibrations, should need no further proof than a careful study of the very able manner in which he discourses, in his *Jahresbericht* article, the graphic representation of the alternate condensation and rarefaction of the air in sound-waves. His insight into this matter was remarkably clear, considering the time at which he wrote, and even the most advanced science of the present day has but little to add to what he has stated as to the representation, by means of graphic curves, of the variations in the density of the air produced by means of sound-waves. His writings show, in the clearest manner, that the prime condition he constantly kept before him, in order to solve the electrical transmission of sounds of all kinds, was the necessity of obtaining an exact reproduction, in the diaphragm of the receiving instrument, of the movements of the diaphragm of the transmitting instrument under the influence of the sound-waves. "The function of the organs of hearing, therefore, is to impart faithfully to the auditory nerve every condensation and rarefaction occurring in the surrounding medium." "That which is perceived by the auditory nerve is, therefore, merely the action of a force affecting our consciousness, and as such may be represented graphically, according to its duration and magnitude, by a curve." "Our ear can perceive absolutely nothing more than is capable of being represented by similar curves, and this method is completely sufficient to bring before our clear consciousness every tone and every combination of tones." "As soon, therefore, as it shall be possible, at any place and in any prescribed manner, to set up vibrations whose curves are like those of any given tone *or combination of tones* (the italics are my own), we shall receive the same impression as that tone or combination of tones would have produced upon us."

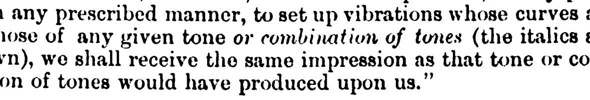

FIG. 15.—Graphic Representation of Condensation and Rarefaction.

"Taking my stand on the preceding principles, I have succeeded in constructing an apparatus by means of which I am in a position to reproduce the tones of divers instruments, yes, and even, to a certain degree, the human voice."

Can any reasonable doubt remain, after reading the above, that Reis could have intentionally designed his apparatus to produce effects contrary to what he so clearly stated as necessary for its success ? This will, perhaps, be made still clearer from an inspection of the tables of curves accompanying his *Jahresbericht* article. These we will reproduce, as well as a translation of that part of the article alluding to them, even though we have quoted some of it previously. We will use for this purpose the translation introduced into the record of the "American Bell Telephone Company *v.* Amos E. Dolbear, *et al*" :—

"What our auditory nerve perceives is, then, simply the effect of a force coming within the range of consciousness, and this force can be represented, both as to duration and magnitude, graphically by a curve."

"Let *a*, *b* (Fig. 15) represent any given time, and the curve above the line condensation (+), the curve below the line rarefaction (−), then any ordinate raised from the end of any abscissa will represent the degree of condensation at the time represented by its base, in consequence of which the drum of the ear vibrates.

"Our ear can, under no circumstances, appreciate more than can be represented by these curves, and this, indeed, is entirely sufficient to give us a clear perception of any tone (*Ton*) or any combination of tones.

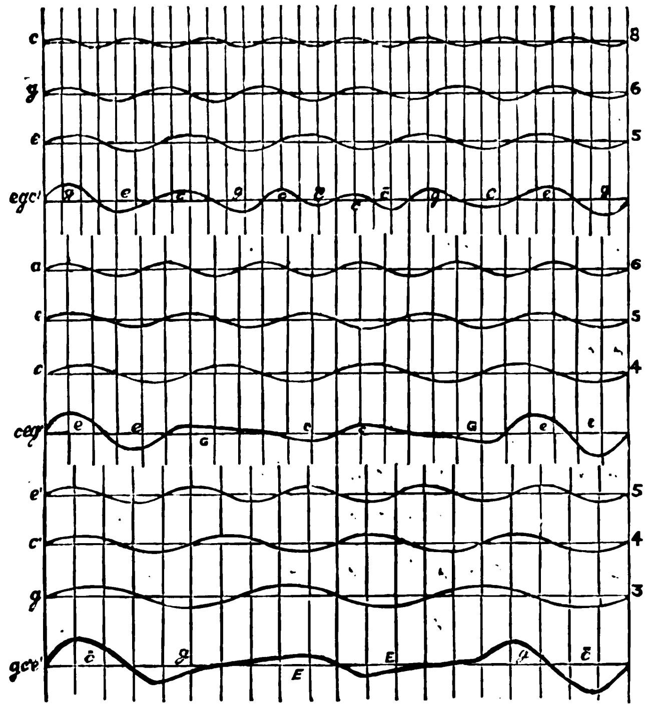

FIG. 16.

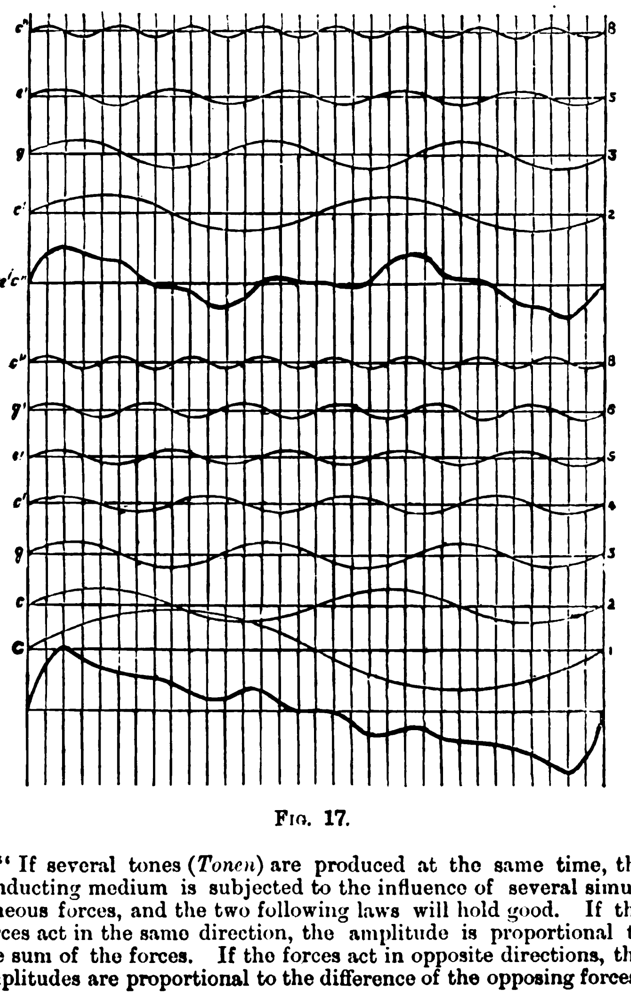

FIG. 17.

"If several tones (*Tonen*) are produced at the same time, the conducting medium is subjected to the influence of several simultaneous forces, and the two following laws will hold good. If the forces act in the same direction, the amplitude is proportional to the sum of the forces. If the forces act in opposite directions, the amplitudes are proportional to the difference of the opposing forces.

Digitized by Google

"If, for example, in the case of three tones, we draw the curve of condensation of each separately, then by a summation of the ordinates of corresponding abscissæ we can determine new ordinates and develop a new curve, which might be called the combination curve. This represents exactly what our ear perceives of the three simultaneous tones. The fact that the musician can distinguish the three tones need not surprise us any more than the fact that any one acquainted with the theory of colours can in green discover blue and yellow ; but the combination curves in Fig. 16 show that this difficulty is a slight one, for in these curves all the relations of the components successively recur. In the case of chords, of more than three notes, the relations are not so readily seen from the drawing, Fig. 17, for example. In the case of chords, however, the skilled musician also finds difficulty in recognising separate notes.

(To be continued.)

SOCIETY OF ARTS.

We extract the following remarks from Sir F. Abel's Presidential Address, inasmuch as they bear more or less upon the development of electricity in lighting matters :—

There are some mines so free from fire-damp that naked lights, in the form of candles or oil lamps, may be used therein with perfect safety as illuminating agents, and others where the occurrence of fire-damp being confined to some few localities, the use of safety lamps need apparently be only insisted upon in certain parts of the workings. There can be no doubt, on the other hand, that the adoption of even the most perfect ventilation cannot secure such absolute safety as to render the use of naked lights warrantable where seams are worked in which fire-damp exists in any abundance, because danger may there arise at any time, from some accidental stoppage or partial failure of the ventilating arrangements, from the effect of a reduction of atmospheric pressure in promoting the escape of gas from lurking places, or from a liability to the sudden emission of gas in considerable quantity from coal, to which reference will presently be made. The very poor light furnished by the forms of safety lamp still chiefly in use, and the consequent increase in the difficulties of working and in the risk to which the miner is exposed from sudden falls of coal or stone, have afforded very strong temptation to the men who have recourse to naked lights, and to the managers of mines to regard such proceeding with indulgence, even where its danger is well recognised. The strongest incentives have, therefore, existed to the application of inventive and constructive ability, either to the improvement of the light furnished by existing forms of safety lamps, or to the production of new forms of lamps presenting decided superiority over them in light-giving power.

It is, however, not only in this direction that the miners' lamps have needed and received improvement ; the poor light furnished by the older forms of lamps in a quiet atmosphere becomes even much worse when they are exposed to such currents as are now met with in properly ventilated mines. In order, therefore, to afford that advantage over naked lights from the simple point of view of efficiency for working purposes, which shall tend to secure its preference over these, the lamps should burn brightly and steadily even in strong currents of air. Lastly, though first in order of importance, the lamp should be unable, under any circumstances at all likely to arise in coal mines, to ignite an inflammable or explosive mixture of fire-damp and air, even when this is passing at the highest velocities which can occur in any part of a mine.

The importance of determining how far modifications of existing lamps, or new kinds brought forward from time to time, fulfil the latter condition, has led individuals specially interested in the subject, and associations of mining engineers, for many years past, to submit lamps to comparative experimental tests ; and the first branch of inquiry which was taken up by the Royal Commission, and which has been steadily pursued by the members up to a quite recent date, was the systematic comparison of the behaviour of different lamps in currents of explosive mixtures of gas and air, travelling at different and accurately-determined velocities. More than 200 different lamps, partly received from various manufacturers and inventors in this country, and partly from France, Belgium, and Germany, have been submitted to tests in explosive atmospheres, under variously modified conditions, representing, as far as possible, every variety of cirumstances under which the lamp might be employed in a mine. Collateral experiments have been made upon the relative merits in point of safety and efficiency of different illuminating agents susceptible of employment in safety lamps. The experiments have been carried out by the Commission, partly at particular collieries in South Wales and Lancashire, where natural blowers of fire-damp, which are piped to the surface, furnished the supplies of gas with which the tests were made ; and partly at Woolwich Arsenal, where special facilities were furnished for accurate and extensive experiment.

The results of these extensive investigations will now very shortly be in the hands of the public, and I must not presume to do more than indicate their general nature.

Until within a comparatively recent period, only three types of lamp were in extensive use in this country—the original safety lamps which the miners owe to the genius of Davy and of Stephenson, and a lamp not long afterwards devised by Dr. Clanny. When the safety lamp was first invented, the ventilating currents in mines were very moderate, seldom attaining a velocity of even 5ft. per second in the principal roads or air-ways, while in the working places themselves the currents were very slight. The Davy, Stephenson, and Clanny lamps were safe under these conditions in the presence of fire-damp. But at the present time air currents in the main roadways of mines often travel at a rate of 20 to 25ft. per second, and at the working places their velocity ranges from 5 to 15ft. per second. Moreover, it is even possible that under special conditions, which may obtain in particular parts of the mine, current velocities of 30 to 35ft. may be met with. Under conditions such as these, the Davy and Clanny lamps cease to afford any security, and it has been demonstrated by the experiments of the Commission that even the Stephenson lamp, which is generally extinguished by an atmosphere highly charged with fire-damp, may bring about an explosion in currents of fire-damp and air. These facts had already been indicated by the results of previous experiments when the Commissioners commenced their work, but their own investigations so clearly established the great danger of relying upon the Davy and Clanny lamps, and the facts already known on the subject appeared to have received so little attention on the part of managers of mines (great confidence in the safety of those lamps having even been expressed by experienced witnesses), that the Commissioners considered it their imperative duty to direct the attention of the Home Secretary to the fact "that the employment of the ordinary Davy lamp, without a shield of metal or of glass, in an explosive mixture, when the air currents exceed 6ft. a second is attended with risk of accident almost amounting to certainty," and that "the Clanny lamp, when tested in a similar current, has proved to be scarcely, if at all, less dangerous." They hoped that the most prominent publication would be at once officially given to this warning. After some delay a circular embodying the substance of it was issued, but without any indication that it bore the authority of the Royal Commission. This action was taken as far back as December, 1880 (they having been appointed early in 1879), yet the Davy and Clanny lamps have continued in use in mines where the elements of danger insisted upon by the Commissioners exist.

The Davy lamp had some years back been rendered much less dangerous when exposed to strong air currents by the addition of a metal shield partially surrounding the gauze cylinder, or by the provision of an external glass cylinder extending up the gauze to various distances. The latter modification, known as the Jack lamp, if properly carried out, proved to be the most efficient safeguard of the two ; a much more important protection has, however, been comparatively recently afforded to the Davy lamp by enclosing it in a case, which protects it to a great extent from the action of currents, but which, at the same time, even when constructed with glass on all sides, considerably diminishes the already very meagre light afforded by this lamp.

A lamp of Belgian origin, termed the Mueseler, and which has for many years past been officially adopted for use in the Belgian mines, presents important advantages over the lamps already referred to. These were recognised by the experimental committees of the leading Institutions of Mining Engineers before the appointment of the Royal Commission, and the lamp was then being introduced into some collieries, an action which has since then extended considerably. Some experiments and certain results of practical experience had, however, already tended to throw some doubt upon the wisdom of placing absolute reliance in the safety of this lamp, especially when the precise details of its construction, as worked out in Belgium, were more or less departed from by English makers. The results of the Commission's experiments confirmed the doubts which had been raised by experiments of the Midland Institute respecting the absolute safety of the Mueseler lamp, even when carefully constructed as regards the proportions of its component parts, and demonstrated that, under special circumstances, it might cause an explosion when exposed to a current of fire-damp mixture having a velocity of from six to ten feet per second. Under corresponding conditions, and even in currents of much higher velocities, the cased Davy lamp was found to be perfectly safe, and the establishment of this important fact has led to the adaptation of cases in various ways to the old types of safety lamps, many so-called new safety lamps consisting, in fact, of the Davy or Clanny protected, by enclosure in various ways, from the direct action of the current.

Protracted as have been the investigations which the Commissioners have carried out with safety lamps, their publication will, I

Digitized by Google

venture to affirm, convince even those who, because they have not cared to inform themselves of the character and extent of work which was being done, have thought it right and just to publicly reproach the Commission with dilatoriness, that the curtailment of these researches would only have been detrimental to the conclusive, and therefore practically important, nature of the results arrived at. For these have not only led to decisive conclusions regarding the defects of the best known and most extensively used types of lamps, and the degree of safety and other merits of a large variety of modifications of them, as well as of new forms of lamps, but they will also enable the Commissioners to indicate with confidence several lamps which combine a great degree of safety with other important merits, and to specify a few among these which, while ranking highest in point of safety, and leaving very little to be desired in this respect, combine with this first essential the important adjuncts of simplicity of construction and fair illuminating power. It will, moreover, be possible to indicate some directions in which even these lamps are susceptible of improvement. It, therefore, only remains to be hoped that the results of the labour which the Commissioners have devoted to this branch of their inquiry will be accepted with the confidence they merit, and will be speedily utilised both by those who are responsible for the management of mines and by those who control the actions of the miner.

When the Commission's investigations of the relative merits of different lamps were already considerably advanced, Mr. Ellis Lever publicly offered a premium of £500 for a miners' safety lamp, either a perfectly self-contained electric lamp, or other lamp, which, while being of convenient size for carrying about, would continue to give a useful amount of light for not less than twelve hours, *and which would "not cause an explosion of gas under any circumstances at all likely to represent conditions which may occur in actual practice."* It was proposed that the judges to whom lamps submitted for competition were to be referred should include three scientists, nominated respectively by Mr. Lever, by the Royal Society, and by the Society of Arts. No less than 108 different lamps were sent in, and it need scarcely be said that the determination whether any among them fulfilled the prescribed conditions involved a very extensive series of experiments. The adjudicators appointed included two members of the Commission, who cheerfully consented to take upon themselves this very considerable addition to the voluntary labours already being carried on by them in the interests of the miners.

In arranging for and carrying out the tests of these lamps, the adjudicators had the great advantage of the experience gained by the Commission as to the nature of tests best adapted to elicit information regarding the good or bad features of a lamp, and as to the performances of the different types or modifications of lamps already known.

Only four electric lamps were submitted, and these altogether failed in fulfilling any one of the conditions laid down, excepting that of being self-contained lamps. As the tests of the various other lamps progressed in severity, the number of promising ones was rapidly reduced, and eventually not one lamp was found completely to fulfil the whole of the conditions under which the premium was offered, although there were several which ranked very high as regards safety and efficiency; foremost among these being the lamp of M. Marsaut (with three gauzes) and that of Mr. N. Morgan, of Pontypridd. To the constructors of these lamps gold medals have been awarded at the Inventions Exhibition, and it will be found that they rank among the lamps which the Commissioners are able to speak most highly of. But the premium which Mr. Lever placed at the disposal of the adjudicators reverted to him, and those who have great experience of the behaviour of safety lamps of the various well-known and recently developed types could scarcely have anticipated a different result, in face of the conditions laid down. Mr. Lever has since then again offered a similar premium, this time for "the invention or discovery of an economical, efficient, and safe substitute for gunpowder and other dangerous explosives used in the getting of coal." The Council of the Society of Arts could not see their way to attempt to comply with the suggestions of Mr. Lever that they should award this premium or appoint adjudicators for that purpose. Apart from the circumstance that there would be much less probability of the owner of the money being called upon to pay the premium, than in the case of the lamp competition, the Council could not have presumed even to suggest the great sacrifice of time in the performance of the very laborious and exhaustive experiments indispensable in this case, to such as would be really competent to perform the work of adjudication, which Mr. Lever appears to think at least as lightly of as of the offer of these prizes. It borders upon the amusing to observe in the article by the Manchester correspondent of *The Times*, to which such prominence was given on the 27th of last June, how the writer heralds offers of subscriptions and of premiums as illustrating the way in which his hero "gallantly attacks the problem (of accidents in mines) at all points," while he has no encouraging word for the men of science whose disinterested devotion to very arduous work, for which their sole probable recognition would be hostile criticism, or worse, can alone give any point to the "gallant attacks" of philanthropists like Mr. Ellis Lever.

The possibility of applying the electric light to the illumination of coal mine workings was one of the most prominent of the subjects which first suggested themselves to the Royal Commissioners as demanding careful study. The superficial observer, in noting the real progress made during the last few years in the facility and success with which the electric light has been utilised equally upon a large scale, for purposes of display or for the lighting up of large areas and buildings upon the comparatively small scale needed for illumination of small dwelling houses and offices, and upon the very minute scale, as in connection with surgical requirements, might have been pardonably led to the conclusion that there existed no very great difficulties in the way of at once presenting the miner with an electric light in almost as portable a form as a safety lamp, incomparably safer than the best of these, and capable of affording him a much superior light for the entire duration of his longest working hours underground. A little inquiry into the subject demonstrated to the Royal Commission that such a conclusion would be at least very premature, and that, although the subject was one most worthy of patient pursuit, the attainment of really useful results was beset with formidable difficulties. It is one thing to announce in oracular fashion, as *The Times* did, in a leading article last June, "that collieries ought to be lighted in a way to dispense with safety lamps," "that electricity is the one illuminating medium which can supply the light which miners want, without the flame which endangers them." It is quite another thing to apply the electric light with safety, even along main roadways, in mines in which fire-damp is prevalent. The writer of those lines would have been less confident in his assertions had he sought sufficient information to teach him that the fracture of a glow lamp, or the rupture of a conducting wire in a mine might be as much fraught with danger as the injury of a safety lamp or the lighting of a pipe. Had he, moreover, but learned by simple inquiry what progress had been made by patient workers at the time he was inspired thus to write towards setting aside those sources of danger, and providing the miner with a portable and efficient self-contained lamp, he would certainly have hesitated to assert that "no proper zeal has been brought to bear upon the conquest of difficulties in the application of electric lighting in mines, or to sneer at "the scientific brains, whom the public may encourage, though it cannot compel, to exert themselves as keenly for the illumination of a murky, dirty coal pit, as in the transformation of a plot of ground in South Kensington into fairyland."

The Royal Commissioners' report will deal with attempts which have been made in several of the mining districts to apply electricity to underground illumination; so far as distribution of the light in main roads is concerned, no great progress has been made, though there is now no reason why glow lamps, protected after the manner in use at our Government Gunpowder Works (as shown at the recent Exhibition), should not be distributed to considerable distances along such portions of a mine, the conducting wires being placed in secure positions and effectually protected. At Risca Colliery, in Monmouthshire, at Harris's Navigation Colliery, near Pontypridd, and at Earnock Colliery, at Hamilton, N.B., a commencement has already been made in this direction with satisfactory results. If, however, the miner is to have an electric lamp for lighting up drifts and working places, it must be supplied to him in a self-contained and really portable form, with absolute protection or isolation of the glow lamp from the surrounding atmosphere, and with a store of power sufficient to maintain an efficient light for ten or twelve hours.

The considerable improvements which have of late been made in secondary batteries, or accumulators, and the advance which has also been made in the construction of constant primary batteries, have led to very important progress towards the attainment of these essentials since lamps were submitted for competition for the Lever premium about two years ago. Mr. J. Wilson Swan, universally celebrated for his achievements in the matter of glow lamps, who was encouraged by the Commission in the early days of its existence to give his attention to the adaptation of the glow lamp to the miner's use, and has since patiently pursued the subject, has not long since succeeded in producing a lamp which, with its small storage battery, weighs little more than 8lb., and which will furnish a light equal to from two to four times that given by the better forms of safety lamp for a duration of ten or twelve hours. The beautiful miniature glow lamp which furnishes the light is perfectly shut out from the air and protected from accidental fracture, and the battery will bear swinging about without detriment. Mr. Swan is sanguine that he will ere long be able to effect an important reduction in the weight and bulk of the lamp, and he is not less hopeful of elaborating a primary battery similar in portability and light-giving power, the substitution of which, if successful, for the accumulator would have the advantage of dispensing with the necessity for providing

Digitized by Google

dynamo-electric machines and power for charging the storage cells, though the great advantages presented by electric illumination, especially with arc lamps, of the surface establishments of a colliery, will probably lead ere long to the extensive employment of dynamo machines for such purposes. Other workers besides Mr. Swan, such as Mr. Coad and M. Trouvé, have been applying small primary batteries to the production of miners' lamps with some promise of success, although, as yet, the results furnished do not bear comparison with those obtained by Mr. Swan with the storage battery. Those who have spent any length of time under ground, especially in the very low workings which abound in coal mines, and at the high temperature which often prevails in the workings of deep mines, will have experienced the fact that any incumbrance may sometimes become very burdensome, and can well understand, therefore, that the weight and size of even the lightest form of battery with which an efficient light could be maintained for a sufficient length of time may prove grave obstacles to its extensive employment. Moreover, as the electric light can afford no indication of the condition of the atmosphere in a mine-working, its employment may not, even under the most favourable conditions, altogether allow of the safety lamp being dispensed with. But even if used only as an auxiliary means of illumination in working places, such lights as those which Swan and others will supply will prove very valuable. A similar lamp of somewhat larger size and comparatively much greater illuminating power may also prove invaluable for exploring purposes, especially after accidents due to outbursts of gas, when the best safety lamps may be of little use, even if they continue to burn. Such electric lamps must, indeed, become formidable competitors of the Fleuss lamp (included in the recent Exhibition), which has, in conjunction with the portable apparatus for the supply of respirable air to explorers, already performed important service in rendering access to mine workings possible where an ordinary lamp could not burn, and where the atmosphere was too foul to support life for any time.

THE INSTITUTION OF CIVIL ENGINEERS.

At the third ordinary meeting, held on Tuesday, the 24th of November, Sir Frederick J. Bramwell, F.R.S., president, in the chair, the first paper read was on "High Speed Motors," by Mr. John Imray, M.A., M. Inst. C.E.

The second paper read was on "Dynamo-Electric Machines and their Engines," by Mr. Gisbert Kapp, Assoc. M. Inst. C.E., of which the following is an abstract:—In this paper the author summarised the improvements which had been made within the last few years in the design and construction of dynamo-electric machines and engines used to drive them. Starting with the mechanically imperfect machine first introduced by Gramme, he showed how, by degrees, the nature of the strains occurring in those machines became better understood, and engineers began to employ adequate means to meet those strains. Also how, by a better arrangement and proportioning of the various parts, the efficiency and power of these machines had been increased, while at the same time their weight and price for a given power had been reduced. Those improvements had mainly been effected in the armatures and the field-magnets. The former consisted in holding the wires firmly in place, and in admitting air to all parts of the wires, and, in some cases, also to the core of the armature. Another improvement consisted in supporting the core by solid metal spokes or arms, instead of by the old-fashioned wooden hub. As regarded the field-magnets, the substitution of soft well-annealed wrought iron for cast iron had enabled the makers of dynamo machines to increase the electromotive force from 20 to 30 per cent., and also to obtain machines which were almost self-regulating. In consequence of the ventilation of the armatures, the density of current carried by the wires had been increased considerably, in some cases even up to 6,000 amperes per square inch, although the general practice was to employ only 2,500 amperes. The author next classified the dynamos, according to their armatures, into there great divisions; first, dynamos with armatures wound on the Hefner-Alteneck principle; second, those with cylindrical armatures, wound on the Gramme principle; and, third, those with disc armatures, wound on the Schuckert principle; and he gave a formula by which the electromotive force created in any of these armatures could be calculated from the constructive data of the machines. The question of the length of conductor required for every volt of electromotive force produced in the external circuit was next inquired into, and after certain assumptions, which were fairly in accordance with general practice, he found that the length of conductor required to produce one volt was as shown in next column.

Speaking of the intensity of the magnetic-field in a dynamo-machine, the author established the relation that the total number of lines of force passing across the armature could be represented as the ratio of the exciting power and magnetic resistance, the latter consisting of three parts; that properly due to the field-magnets, that due to the armature core, and that due to the air-space between the polar-surfaces and the surface of the armature core. The latter was assumed to be constant for all degrees of magnetisation, but the two former were supposed to increase in a certain way with the intensity of magnetisation; this increase, however, not being taken into account for low intensity. Formulas were then given for the magnetic resistance, from which it was found that the dynamo machines with single horse-shoe magnets required about 25 per cent. less wire than those with double horse-shoe magnets. With regard to the influence of the size of dynamos on the electrical energy which could be obtained from them, the author found that in small and medium-size machines the latter varied as the $3\frac{1}{2}$ power of their linear dimensions, and that the cost of manufacture varied as the $2\frac{1}{2}$ power, thus making the cost of the dynamo per lamp inversely as its linear dimensions.

	Inches.
1. Drum, long - - - - - - -	6 5
2. ,, short - - - - - - -	16·4
3. Cylinder, long - - - - - -	21·8
4. ,, short - - - - - -	26·1
5. Disc, square core - - - - -	26·3
6. ,, circular core - - - - -	26·3
7. ,, flat core - - - - -	78·8

The influence of the electromotive force on the cost of dynamos was shown by an example, which proved that, for economical reasons, it was better to work with average electromotive force, and that very high tension should only be employed if the expense for cables in the external circuits became very considerable. Detailed descriptions were given of nearly all the improved dynamo machines now manufactured in England, including the Edison-Hopkinson, Mather and Platt, Paterson and Cooper, Elwell-Parker, Crompton, Greenwood and Batley, the Brush Company, the Gülcher Company, and the author's dynamos. A table was also given which contained some of the more important constructive data of the various dynamos described, especially with regard to the density of current in armature and magnet wires, and the cooling surface provided to dissipate the heat which was necessarily generated by the current passing through those wires. As regarded the engines, the author maintained that the necessity of durability and economy in steam engines was as great if they were required to work dynamos, as in cases where they were used for driving mills, propelling vessels, or for any other purpose, and that, therefore, electricians should not be content with uneconomical engines, or with those which were liable to break down. If engine makers maintained that the speed at which dynamo machines must be driven was too great to allow them to make a substantial engine, electricians must reduce the speed of the dynamo to suit the engine.

The discussion upon these papers will be taken at the next meeting on 1st December.

LANT CARPENTER ON THE ELECTRIC TELEGRAPH.

At the Birkbeck Institution, on Wednesday evening, Mr. W. Lant Carpenter, B.Sc., lectured on the above subject, which he treated, not from a historical but from a practical point of view, dealing especially with the instruments and the principles on which they are constructed, methods for using land lines to their fullest capacity, and submarine telegraphy. The lecture was illustrated by diagrams, thrown by the oxy-hydrogen light, and also by actual demonstrations projected on to another screen, while Mr. Reece and Mr. Wilkinson, tutors at the School of Telegraphy, practically worked a line with a Post Office battery and the Wheatstone transmitter, in presence of the audience. In the course of his lecture Mr. Carpenter observed that in the United States of America dynamos were largely used for producing telegraph currents, but Mr. Preece informed him that he was successfully experimenting with secondary batteries for that purpose. Among the views on the screen was a photograph of a bill issued by the Great Western Railway Company on their first adopting the electric telegraph, inviting the public to come and witness the *modus operandi* of "the wonder of the age" at a shilling a head. The lecturer mentioned one instance, about four years ago, in which Mr. Preece, usually so punctual, had kept him waiting three-quarters of an hour, the cause being a magnetic disturbance which interrupted all the lines. Mr. Carpenter predicted an aurora borealis, which was seen the same night, and he then went on to the offices of the Eastern Telegraph Company, asking if their cables were working, because, if so, they would soon be interrupted, which they were afterwards, and there was no telegraphic news in the next morning's papers. While, with the Morse alphabet, a skilful operator could only send twenty-five words a minute, there were two methods of increasing the work of a wire, viz., multiplex telegraphy as practised in America, with its dryer climate, and the Wheatstone fast-speed trans-

Digitized by Google

mitter, as used in England, by which one punched tape served for twenty or thirty different wires, and 200 words could be sent in a minute, as many as 230 having been transmitted between London and Edinburgh. He referred to the early difficulties connected with ocean telegraphy, and especially the incredulity of the public, who firmly believed that the first Atlantic messages were concocted in London. A view was shown of the artificial electric cable by means of which Mr. Varley succeeded in raising the capital for the first Atlantic cable. An admirable portrait was shown of the late Sir William Siemens, to whom for the cables, and to Sir William Thomson for the instruments, was attributed the chief credit for success in ocean telegraphy. Maps of the ground covered by the Eastern Company's cables were projected on to the screen; and it was stated that there were now 85,000 miles of ocean cables, which cost £30,000,000, while thirty vessels were engaged in laying and repairing, the last cable having been laid in twelve days without a hitch. After explaining the action of Sir W. Thomson's reflecting galvanometer and siphon recorder, and insisting on the importance of messages being written legibly ("Governor turns first sod," having been sent "Governor twins first son"), Mr. Carpenter gave a few statistics supplied to him by Mr. Preece as to sixpenny telegrams. Of the present mileage of 156,000 with 17,000 instruments, 26,000 miles and 900 instruments were due to the 6d. rate. The number of messages for week ended 14th inst. of the present year at the 6d. rate was 895,781 as compared with 638,657 for the corresponding week of last year at the 1s. rate. The number of messages in the last week of the 1s. rate was 670,116, and that of the first complete week of the 6d. rate, 846,745. While the average increase of inland messages has been 40 per cent., that in London was 60 per cent., the average price being 8d., as against 1s. 1d. under the old tariff, the number of registered addresses having increased from 2,000 to 9,000 in London alone. Mr. Carpenter, who had prefaced his lecture by thanking the Birkbeck Committee for their vote of condolence on the decease of Dr. Carpenter, concluded with the words of James Russell Lowell—that of all the benefits which science had conferred there was none greater than that by which a common nervous system transmits a common emotion.

GREENOCK PHILOSOPHICAL SOCIETY.

The third lecture of this session was delivered recently by Professor Jamieson, of the Glasgow College of Science and Arts, on "The Latest Developments of Electric Lighting for Houses, Ships, and Mines,"—Mr. Edward Blackmore, president of the society, in the chair. After reviewing the progress that had been made in electric lighting on the incandescent principle, and stating generally the number of private houses, as well as ships and mines that had been lighted within the last four years, Prof. Jamieson referred to the electric railways at Portrush in Ireland, Brighton, and Blackpool, as well as the system of telpherage at Viscount Hampden's, in Sussex, and drew an analogy between the flow of water in pipes and the electric current through wires, explaining the meaning of the various electrical terms used by electricians to denote pressure, resistance, current, and power, and showing how the terms understood by all in the one case helped to an understanding of the other. He then showed how it was that large currents of electricity could not be so economically produced from ordinary primary batteries (on account of the expense of the materials consumed) as could now be generated by a steam engine, gas engine, water wheel, or turbine driving a dynamo; and he illustrated the construction and principle of the dynamo by freehand sketches on the black board and several large wall diagrams. The construction of the incandescent lamp was similarly treated, as well as the accumulator or secondary battery. He reminded his audience of the box containing stored electrical energy which had been sent to Sir William Thomson about three years ago from Paris, and upon the report which Sir William had given of it, all of which, he said, had now been more than fulfilled, for the very storage batteries which he was using to light up the lecture-table and diagrams with had been in constant use for sixteen months, and, as far as could be ascertained, they were just as efficient now as when they first arrived in Glasgow. He next gave an example of how a private house might best be lighted, taking, as an example, Mr. Preece's house at Wimbledon. Further, he gave the results of a very careful estimate for a sugar house or factory, where upwards of 300 gas jets were now in use, proving that with that number of lights the electric light would be the cheaper of the two forms of lighting by about 9 per cent. per annum. Ship lighting was then discussed by the lecturer, and the great advantages it possessed over oil and candle lighting; for, as he said, it was cooler, more easily manipulated, more artistic; there was no smell and no products of combustion to tarnish gilt work or destroy drapery and books. He showed various designs for ship fittings, lighted by accumulators on the lecture platform, as well as some beautifully designed transparent vases and fittings to illustrate house decoration. Finally, he showed what was evidently of great interest to the audience, viz., an electric miner's safety lamp. This lamp and its electric charge, capable of keeping it alight for about ten hours at over one candle-power, was handed round, and its advantages pointed out. It could, he said, be taken down into a fiery or dangerous mine without fear of causing an explosion, as the glowing carbon filament was contained in a miniature Swan lamp.

THE ELECTRIC LIGHT.

Notification is given of an intended application to Parliament in the ensuing session for leave to bring in a Bill to extend the time limited by the Electric Lighting Act, 1882, or by the Saint James, Saint Martin, and Saint George, Hanover-square (West London), Electric Lighting Order, 1884, and the Electric Lighting Order Confirmation (No. 3) Act, 1884, or any one or more of them, within which any local authority might require the West London Electric Lighting Company (Limited) to sell their undertaking for such period, and, if need be, to alter the terms and conditions of such sale, in such manner as might be provided by the Bill. The Bill will contain clauses extending the time within which the local authority may, under the provisions of the order, serve a notice on the company requiring them to apply to the Board of Trade to direct that any part of the area included in Schedule B shall be added to the area included in Schedule A respectively annexed to the order, and also to extend the time within which the local authority, on the failure of the company to apply to the Board of Trade, may apply to the Board to remove such part or parts from the operations of the order. Further clauses will be contained in the Bill to extend the time within which the company are or might be required by the order to lay down distributing mains for the purposes of general supply, as defined in the order, and to exempt the company from any penalty thereto; providing that Section 27 of the Electric Lighting Act of 1882 shall not apply to the company or their undertaking, and prescribing "the terms and conditions on which any sale or purchase (if any) of the undertaking or any part or parts of the undertaking of the company as aforesaid, may be required to be made." Powers will also be asked as the acquisition of land.

Application will be made by the Chelsea Electricity Supply Company (Limited) to the Board of Trade on or before the 21st prox., under the provisions of the Electric Lighting Act, 1882, for a provisional order authorising the company to produce, store, and supply electricity within the parish of Chelsea. The Bill will contain clauses of the usual description, giving the company powers to construct the necessary works; to lay down wires and other apparatus, and to break up streets in the localities proposed to be supplied; to acquire land, to levy "rates, rents, and charges for the supply of electricity and the use of any machines, lamps, meters, fittings, or apparatus connected therewith;" and to make agreements with the local authorities. The notice further states:—"The streets and other places in, over, or along which it is proposed to take power to place any electric lines or other works are all the streets and other places within the said area of supply. And among such streets and places it is more particularly proposed to place electric lines and works in, over, and along the whole or portions of the following streets and places (but not to the exclusion of the other streets and places within the said area), that is to say:—Pavilion-road, Hans-place, York-street, Vincent-street, Pont-street, Grove-place, Walton-street, Walton-place, Lennox-gardens, Milner-street, Cadogan-square, Cadogan-terrace, Cadogan-street, Draycott-place, Draycott-street, Sloane-street, Cadogan-place, D'Oyley-street, Little Cadogan-place, Elizabeth-street, Ellis-street, Sloane-square, Lower George-street, Halkin-terrace, Westbourne-place."

LIGHTHOUSE ILLUMINANTS.—ELECTRIC LIGHT APPARATUS.

REPORT OF PROF. W. GRYLLS ADAMS, F.R.S., &c.

Description of Machines.

The machines now being tested at the South Foreland are three De Meritens alternate current magneto machines of the largest size made by him, having 60 permanent magnets, arranged in five rings of 12 magnets and 24 coils on each ring of the revolving armature. Each coil consists of four layers of wire, and is 27 millimetres deep, and about 100 millimetres wide. The 120 coils when arranged in parallel circuit for lighthouse work have a resistance of about one-twentieth of an ohm. The three machines are distinguished as L No. 1, L No. 2, and L No. 3, and their internal resistances are ·044 ohm, ·49 ohm, and ·056 ohm respectively.

The five rings of coils on each of the machines are connected in parallel circuit when all the brushes are down, but the collectors and brushes on each machine are made in three sections, so that it is possible to employ one ring only of magnets and coils, or two rings only, or the remaining three rings, or the whole five rings together, by bringing the respective brushes in contact with their own collectors, which are insulated from one another by ebonite rings or flanges on the ebonite axis which insulates the collectors from the axis of the machine. The diameter of the armature carrying the revolving coils is 2ft. 6in., or 760 millimetres, and the driving pulley is about 16in., or 400 millimetres, in diameter.

When revolving at the normal speed, 600 revolutions per minute, the magneto machines have been found to work with very great steadiness and with great efficiency. The electromotive force is about 75 volts and $\frac{2\pi\gamma}{T} = \cdot 3$ ohm nearly, where γ is the coefficient of self-induction and T the periodic time of the machine. When running with the circuit open, a very considerable amount of work is spent on the friction and internal work within the machine, but on closing the circuit this is greatly diminished, and the output of the machines, or the electrical energy in the external circuit, exceeds the *additional* work done to produce it. Thus, a single machine absorbs 4·2 horse-power when running at 600

Digitized by Google

revolutions with the circuit open, yet only absorbs 10·4 horse-power with the circuit closed with one arc lamp in circuit, when it yields in electrical energy in one case 6,000 watts, or 8 horse-power, and and in another 6,600 watts, or 8·8 horse-power, in the external circuit. In the same way, two machines when clutched together and working in series, so as to work two arcs in series, absorb 9·35 horse-power when running at 600 revolutions with the circuit open, and yet were found to absorb only 20·51 horse-power with the circuit closed and two arcs in series, when they yielded in electrical energy 12,500 watts, or 16·8 horse-power, in the external circuit.

Thus, the external efficiency of these machines, when working separately or together in series, was found to be respectively about 81 or 82 per cent. The electrical energy per second is estimated by multiplying the average electromotive force by the average current as measured by an electro-dynamometer, by multiplying the average electromotive force, as given by Cardew's voltmeter, by the average current as given by Siemens' electro-dynamometer.

The electromotive force was also determined by a quadrant electrometer, by joining the needle to one pair of quadrants, when the expression for the electromotive force becomes $(V - V_1)^2 = E^2 = \frac{2d}{k}$, where d is the deflection, and k the constant of the electrometer.

The method of determining the work done in the arc by joining the pairs of quadrants of the electrometer to the two ends of a known resistance placed in the circuit, according to the formula

$$d_1 = k(V_1 - V_2)\left(V - \frac{V_1 + V^2}{2}\right) = kCr\left(V - \frac{V_1 + V_2}{2}\right),$$

was also tried, but the introduction of even a small resistance, r, materially altered the electromotive force and also the current in the circuit, and the method was not sufficiently sensitive. Thus, when the deflection by the first method, or $\frac{k}{2}(V - V_1)^2$, was 120 divisions of the scale for an electromotive force of 57 volts, the deflection by the second method was only about 30 divisions when r was about one-fifteenth of an ohm. The addition of this resistance considerably increased the electromotive force, and diminished the current in the circuit.

At the South Foreland the leads from the machines to the arc lamps in the experimental tower have a resistance of ·066 of an ohm, and when two machines were clutched together and working in series, so as to supply two arcs in series, the yield of electrical energy per second was about 10,200 watts in the external circuit; whereas, when working in parallel circuits through the same leads to one arc lamp, the yield was only about 8,600 watts in the external circuit.

A first series of experiments on the three magneto machines was made in July, 1884.

A second series was made in September, and further experiments on these machines and on the illuminating power of the light from the De Meritens arc lamps fed by them have been made during October, November, and December.

In each series of experiments the magneto machines have been found to work with very great steadiness and with very great efficiency.

When running with the circuit open a very considerable amount of work is spent on the friction and internal work within the machine, but on closing the circuit this is greatly diminished, and the output of the machines or the electrical energy in the external circuit exceeds the *additional* work done to produce it.

On July 11th, machine L No. 3, which supplies the light to the upper of the three lamps in the "A" tower, was first measured, the measurements being made in the engine room at the De Meritens distributor. The E.M.F., with circuit open, was 74 volts.

At first one ring of magnets only was employed to give the current to the arc, giving an E.M.F. of 32·6 volts, and a current of 37 amperes, or about 1,200 watts, *i.e.*, about 1·6 horse-power in electrical energy in the external circuit.

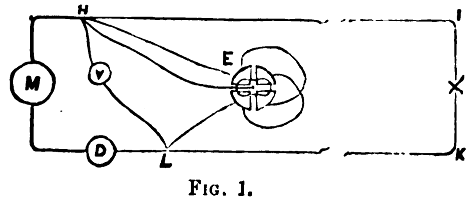

Fig. 1.

Two rings of magnets were now employed, when the E.M.F. became 37 volts, and the average current 65·8 amperes, giving 2,435 watts or 3·26 horse-power.

On employing the five rings of magnets, *i.e.*, the whole machine, and at the normal speed, the E.M.F. became 46·4 volts, and the average current 112·2 amperes, giving an average product E.C. or the average watts of 5,200 or about 7 horse-power the external circuit.

The leads from this machine were attached to a De Meritens arc lamp on the lowest stage in the "A" tower during the above experiments, and the resistance of the circuit was higher than the normal resistance.

On connecting the leads to the arc lamp on the uppermost of the three stages in the "A" tower, the E.M.F. at the terminals on the distributor was diminished to 34·5 volts and the current increased to 135 amperes, a change which was probably due to a diminution in the resistance of the circuit.

The instruments were arranged in the circuit as shown in the accompanying sketch (Fig. 1).

M is the magneto machine.
V the Cardew voltmeter.
D the Siemens electro-dynamometer.
E the quadrant electrometer.
X the electric arc.
HI and LK represent the leads to the "A" tower.
H and L are the binding screws on the De Meritens distributor.

In some experiments the voltmeter or the electrometer was removed from H and L to I and K, the extremities of the arc.

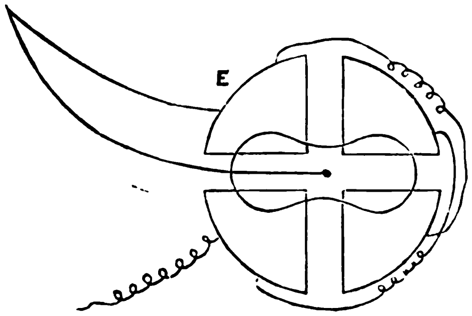

Fig. 2.—Picture of electrometer in the above diagram.

On July 12, machine L No. 1 was measured, and was found to give a current considerably lower than L No. 3 for the same electromotive force.

The current was only about four-fifths of the current given under the same circumstances by L No. 3, and the electrical energy or output of this machine was only about 4,150 watts, or about 5·6 horse-power.

The intensity of the light was estimated by Mr. Dixon in No. 1 hut on the evening of July 12, from 10:40 to 11:0 p.m.; during this period the average E.M.F. was 44·3 volts at the distributor, and the average current was 93·5 amperes, giving about 4,150 watts.

Later experiments showed that in consequence of the resistance of the leads to the tower about ·27 of the total electrical energy was lost by the way between the distributor and the "A" tower.

On July 14, machine L No. 2 was tested in the same way as the other two machines had been tested, and with the following results:—

With the circuit open the E.M.F. was 7·7 volts; on closing the circuit through the arc in the "A" tower, the following readings were taken:—

Revolutions.	Volts.	Amperes.	Watts = Volts + Amperes.	
600	43	123·3	5,302	——
	50	109·8	5,490	
600	47·5	117·0	5,558	
600	48	113·8	5,462	
600	48	115·8	5,558	
	48	113·4	5,443	
	47	118·1	5,551	
	48	114·2	5,481	
Mean 600 –	48	114·6	5,506	= 7·4 horse-power in the external circuit.

The work yielded is 1·2 horse-power greater than the difference between work consumed on closed and on open circuit.

From some cause (not apparent) machine L No. 1 gives less satisfactory results than the other two machines, and L No. 2 gives results slightly better than L No. 3.

L No. 1 gives 4,150 watts or 5·6 horse-power.
L No. 2 gives 5,506 watts or 7·4 horse-power.
L No. 3 gives 5,200 watts or 7·0 horse-power.

Machines L No. 1 and L No. 2 are capable of being mechanically clutched together, either to run in parallel circuit or to run together in series.

A series of preliminary experiments with the two machines in parallel circuit gave the results shown in Table A.

In this case there was one arc lamp and the leads to the "A" tower in circuit, and the high E.M.F. points to the fact that there is too much resistance in the circuit to give good results.

As regards efficiency, 9·35 horse-power is given by the indicator diagram as the work consumed, friction, &c., in driving the two machines with the circuit open; and 18·89 horse-power when the circuit was closed through one lamp; the work yielded being 2 horse-power greater than the difference between the work consumed with the circuit open and closed.

Another trial of L No. 2 in the evening of July 14th, when the Holmes machines were being driven from the same engines, gave slightly lower results, 47 volts, 113·2 amperes, giving 5,316 watts.

TABLE A.

—	Volts.	Amperes.	Watts.	—
	53·5	155·3	8,308	
	54	156·7	8,463	
	54·5	158·1	8,618	
	56	156·7	8,776	
	56	156·7	8,776	
	55	155·3	8,541	
	56	155·3	8,696	
	55	155·86	8,572	
	55·5	155·3	8,618	
	55	155·3	8,541	
	55	155·3	8,541	
Mean -	55	156	8,580	= 11·5 horse-power in the external circuit.

The two machines L No. 1 and L No. 2, were also tried, being clutched together in series, with two arc lamps in series in the "A" tower, and gave the following results —

—	Volts.	Amperes.	Watts.	—
	79	128·5	10,150	
	79	129·2	10,210	
	78	131·6	10,270	
	76	133·0	10,110	
	78	131·2	10,230	
	77	132·9	10,230	
	78	130·2	10,150	
Mean -	78	131	10,193	= 13·7 horse-power.

The horse-power consumed on friction, &c., in open circuit = 9·35.

The horse-power consumed on driving the machines in series in closed circuit through two lamps = 20·51.

Thus the effective horse-power, or electrical work produced in the external circuit, is 2·2 horse-power greater than the difference between the work consumed with the circuit closed and with the circuit open.

The effective work done would probably have been greater but for the inferiority of machine L No. 1.

A second set of experiments with these magneto machines was made on the 18th, 19th, and 21st of July, when supplying the current to an arc lamp in the photometric gallery.

The Cardew voltmeter, the electro-dynamometer, and the quadrant electrometer were also placed in the photometric gallery, so as to measure the E.M.F. at the extremeties of the arc and the work done in the arc alone.

These experiments gave much better results than the previous ones, because the resistance of the leads to the photometric gallery is less than half the resistance of leads to the "A" tower.

As in the previous experiments, when the carbons in the arc were close together, the E.M.F. was low and the current high, the E.M.F. increasing and the current diminishing as the length of the arc increased, but so that the product or work done in the arc remained very nearly constant.

The E.M.F. from machine L No. 1 varied from 33 to 36 volts, and the current from 139 to 128 amperes, the average of work done in the arc being 4,608 watts, or about 6·2 horse-power.

The E.M.F. from machine L No. 2 being 72 volts with open circuit, varied from 34 to 37 volts with the circuit closed; and the current varied from 171·5 to 158·5 amperes, the average of work done in the arc being 6,084 watts, or 8·16 horse-power.

This machine was also employed in the experiments on Saturday, July 19th.

The E.M.F. from machine L No. 3 varied from 33·5 to 39 volts, and the current varied from 166 to 152 amperes, the average of work done in the arc being 5,666 watts, or 7·6 horse-power.

Thus all the machines give about 9 or 10 per cent. more work in the arc in the photometric gallery than they gave at the terminals of the machines when they supplied current to the arc in the "A" tower. This points to the fact that the leads to the "A" tower, and especially those from machine L No. 3 to the upper light in the "A" tower, consume too much work, or are too small.

In the experiments on Saturday, July 19th, with machine L No. 2, in the photometric gallery, the E.M.F. was 76·5 with open circuit, and the E.M.F. at the arc varied from 33·5 to 38 volts; the current varied from 171·5 to 161 amperes; the average of work done in the arc being 6,030 watts, or 8·1 horse-power.

On Monday, July 21, made experiments again with machine L No 2 (in the photometric gallery), when the E.M.F. varied from 35 to 37·5 volts, and the current from 167 to 163 amperes; the average of work done in watts, or the arc being 6,021 watts, or 8·07 horse-power.

On these two occasions the light given by the arc was measured by comparison with the Douglass 2-candle standard by the Bunsen photometer, placed in the photometric gallery at a distance of 341 feet from the arc. During these experiments the intensity of light in the arc varied from 11,000 to 15,000 candles, the greatest amount of light being given when the greatest current was passing, *i.e.*, when the arc is short.

On Monday, July 21, experiments were made with the two machines, L No. 1 and L No. 2, combined in parallel circuit with one arc in the photometric gallery.

The E.M.F. at the extremities of the arc remained very steady, varying only from 37 to 38 volts, and the current varied from 230·34 to 217·54 amperes, giving an amount of work done in the arc = 8,410 watts, or 11·3 horse-power. During these experiments the light given in the arc varied from 13,325 candles to 20,000 candles.

On employing L No. 3 machine again to give light to an arc in the "A" tower, we get an E.M.F. of from 43 to 48 volts, and a current of from 120 to 110 amperes, giving the electrical work at the terminals of the machine about 5,200 watts, or about 7 horse-power.

Being prevented from doing work with the De Meritens machines on the evening of Saturday, July 19th, I tested the Holmes machines by connecting to them the wires from the photometric gallery.

The Holmes machine, for the high light, gave an E.M.F. of 72 volts on open circuit, and an E.M.F. of from 25 to 31 volts with the circuit closed, giving a current of from 29·86 to 27·77 amperes. Thus the average of work done is 800 watts, or about 1 horse-power.

Two Holmes machines were then tried together, being locked together for quantity. Before contact the E.M.F. registered was 74 volts, with open circuit. The E.M.F. of the two machines was found to be 31 volts, and the current turned out by them amounted to 53·45 amperes. The average amount of work done in the external circuit was 1,657 watts, or about 2·2 horse-power.

The Holmes machine, for the low light, gave a current of about 32·5 amperes and 1,200 watts.

As an explanation of the inferiority of machine L No. 1 to the other machines, Mr. Sparling stated that when the machines were set up at the South Foreland, two of the magnets of this machine were set up in reverse position, and were afterwards set right, and possibly they had not fully recovered their magnetism.

It became a question whether, supposing two machines were worked together, the currents would tend to strengthen the weak magnets and improve the machine. It seemed advisable to run these machines together for some time with this object.

Some experiments were made on the running of two machines together, and the results obtained are of very great interest, since they prove for the first time experimentally what has been thought to be impossible, viz., that alternate current machines may practically be used as motors for the transmission of power.

To test whether alternate current machines would work in harmony without being rigidly made fast on the same axis, two machines which are usually clutched together were set running, being joined in parallel circuit, and when they had attained their usual speed of about 600 revolutions a minute they were unclutched, and each was driven only by its own belt. The two machines continued to run together very steadily, mutually governing one another; the electromotive force remained steady at 75 volts on open circuit, the same as the electromotive force of one of the machines which had been previously tested.

The machines were not quite equal in efficiency, for before this experiment one of the single machines had given a current of 135 amperes, and the other 165 amperes, with electromotive force of 37 volts, at the normal speed of 600 revolutions; now on closing the circuit from the two machines through the arc, the electromotive force became steady at 40 volts, and there was a current of 221 amperes, giving 8,800 watts in the external circuit, and the machines continued to run as steadily as if they had been clutched.

The lamp was now put out of the circuit and the machines short-circuited upon one another, without the slightest danger to the machines, owing to their high coefficient of self-induction. The belt was then thrown off one machine, when it continued to run at the same uniform speed, being driven as a motor by the electric current from the other single machine, and the electromotive force was equal to the electromotive force of the machine on open circuit.

An attempt was now made to introduce an arc into the circuit, but the motor immediately began to lose its speed and the arc became fitful with long beats, as in two musical instruments getting out of harmony, the beats increasing as the speed fell and the machine stopped.

A third machine similar to the others, but not placed on the same axis and having no mechanical connection with them, was also driven as a motor by one of the other two machines.

The experiments were resumed in September.

On September 19th, I took down to the South Foreland a box of resistance coils and other resistances, also a galvanometer, a Cardew voltmeter, a quadrant electrometer, and a Siemens electro dynamometer.

The internal resistance of the machines and the leads to the "A" tower and to the photometric gallery were determined.

Resistance of machine L No. 1 = ·044 ohm.
 „ „ „ 2 = ·049 „
 „ „ „ 3 = ·056 „

Resistance of leads from the distributor to the "A" tower = ·07 ohm (cold).

Resistance of wires to the photometric gallery = ·032 ohm (cold).

Four German silver wires, each having a resistance of 0·263 ohm were joined together in parallel circuit, making a resistance of 0·066 ohm nearly, *i.e.*, a resistance nearly equal to the resistance of the leads to the "A" tower, so as to determine the loss of power due to the leads.

We have seen that to the arc in the photometric gallery the machine L No. 2 gives an average current of 165 amperes, giving about 36 volts between the extremities of the arc, *i.e.*, giving about 5,940 watts in the arc = 8 horse-power in the arc.

Digitized by Google

When this machine feeds an arc in the "A" tower the current falls to 114·6 amperes, and the E.M.F. at the terminals is 48 volts, and the watts in external circuit 55·06, or 7·4 horse-power.

When an additional resistance of ·066 ohm (cold) is introduced into the circuit, or ·067 ohm (hot), the current is still further reduced to 102·5 amperes, and E.M.F. between the terminals is 55 volts.

This shows the very great loss due to the resistance of the leads.

On the evening of September 24th, when this resistance was in circuit, the E.M.F. between the terminals of the machine was 55 volts.

The E.M.F. between the points P and L in the accompanying diagram of connections was 47·5 volts, and the E.M.F. between the points I and K, the extremities of the arc in the "A" tower, was 40 volts.

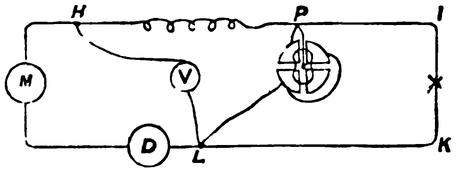

FIG. 3.

For some time previous to September 19 the biform electric light had been exhibited, worked from machines L No. 1 and L No. 2 coupled together in series, and measurements were made on these machines so coupled.

It was found that the E.M.F. at the terminals of the machines was 89 volts, the average current flowing was 143 amperes, giving 12,727 watts in the external circuit.

There was found to be a difference of 15½ volts between the two ends of the leads from the distributor to the "A" tower, so that about 2,180 watts or units of work per second were spent on the leads, leaving about 10,500 to be spent on the two arc lights.

These experiments were repeated on the evening of September 22, when the average E.M.F. was 92 volts, and the average current 132 amperes, giving 12,144 watts in the external circuit.

As these machines seemed to be giving better results than they did in July, machine L No. 1 was tried alone on September 23, when with an average E.M.F. of 43 volts between the terminals, giving an E.M.F. of about 37 volts between the extremities of the arc, the average current was 160 amperes, giving 6,880 watts in the external circuit, and 5,920 watts, or nearly 8 horse-power in the arc.

Thus, the running of the two machines together in series has greatly improved the weaker machine.

Machine L No. 1 is decidedly more efficient than it was in July, and is very nearly equal to machine L No. 2, and certainly more efficient than L No. 3.

——	E.M.F.	Amperes.	Watts (E.C.)	H.-P.
Machine L No. 1	43	160	6,880	9·2
" "	41	165·5	6,786	9·1
" " 2	41	164·4	6,740	9·0
" " 3	40	156	6,240	8·4

In all these cases the machines were supplying current to an arc in the photometric gallery.

Another experiment gave for—

——	E.M.F. at terminals.	E.M.F. at the arc.	Amperes.	Watts.	H.-P.
Machine L No. 2.........	38	32	176·2	6,896	9·2

On September 24, four German silver wires were combined to give a resistance of 0·657 ohm (cold).

The E.M.F. between the terminals was 57 volts (by Cardew), and the deflection of the electrometer 122.

The following simultaneous observations were taken :—

Volts by Cardew.	Electrometer.	Volts by Electrometer. $d=\frac{k.}{2}E^2$ $\therefore k=\frac{2d}{E^2}=\frac{480}{80^2}=\cdot075.$
80	240	80
57	122	57
55	114	} 55
55	113	}
53	105	53
37	50	36·5
32	39	32·25
40	60	40
35	47	35·4
41	62	40·7

This shows that ·075 is the true value of the constant for the electrometer, and that the readings of the two instruments are quite consistent and trustworthy.

The needle and one pair of quadrants of electrometer were now attached to the other end of resistance, when the readings were :—

Cardew.	Electrometer.	Volts by Electrometer.	Current.
52	76	45	—
55	90	49	100·1
55	85	47·6	102·46
53	78	45·6	107·2

giving a difference of potential of about 7 volts at the extremities of the resistance wires.

The resistance of these wires (cold) was 0·657 ohm, and the change of temperature, as roughly measured by bringing a thermometer in contact with German silver wire, was 90° C. Increase of resistance of German silver wire = ·04 p.c. for 1° C. ; hence the resistance = ·0681. Multiplying this by the mean current, 103·6 amperes, we get the product C.R. = 7·055 volts.

Now the resistance of the leads to the "A" tower is very nearly the same resistance as these wires, or ·077 ohm ; hence there must be a difference of potential of about 7 volts at the extremities of the leads to the "A" tower when a current of about 100 amperes is flowing through them.

The above comparison between the Cardew voltmeter and the quadrant electrometer shows that the Cardew instrument is a very satisfactory one for the determination of the electromotive force.

(To be continued.)

NOTES.

BURNT DOWN.—We are advised that the Simplex Electric Light Company's Works, Eccles Valley Mill, were burnt down at two a.m. on Wednesday last.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th November amounted to £3,050.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for November amounted to £56,245, and to £55,640 in the corresponding period of 1884.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of November were £2,021, against £1,729 in the corresponding period of last year.

THE ELECTRIC LIGHT IN BELGIUM.—We understand that the Courtrai Railway Station in Belgium is to receive an installation of the electric light. The firm of Bouckaert has been entrusted with the work.

THE TELEPHONE IN HONOLULU.—The Hawaian Bell Telephone Company at Honolulu have already a list of 400 subscribers. On other of the islands different companies are pushing their business rapidly.

THE PERSIAN GULF CABLE.—A telegram from Colonel Bateman-Champain announces the arrival of the ss. "Dacia" at Kurrachee, after the successful laying of the New Persian Gulf cable from Jask to Bushire.

THE TELEGRAPH BATTALION.—The "Poonah" is on her way from the Cape to Portsmouth, where she may be expected about the 9th instant, with the telegraph section of Royal Engineers, time-expired men, and invalids.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 30th November are £2,108, as compared with £2,344 in the corresponding period of 1884.

ELECTRIC LIGHTING OF TRAINS.—On the occasion of the visit of the King and Queen of Wurtemberg to Nice not long ago the Royal carriage was lighted by electricity. Their Majesties expressed satisfaction with the beautiful illuminant.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This company give notice that their traffic reciepts for the month of November amounted to £40,427, and to £42,286 in the corresponding period of 1884.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 27th November were £2,385, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

A GOOD IDEA.—It is stated that M. Menier, the electrical engineer and contractor, has bought a large property in the Rue de Chateaud'un, Paris, which he is rebuilding. He proposes to sell the electric light at a reasonable rate to all the lodgers in the house.

PHOTOGRAPHY.—It is stated that the electric light is about to be introduced in the photographic studios of M. Langlois, Boulevard de Strasbourg, Paris. The installation will consist of three Gramme arc lamps, a Gramme dynamo, and a Popp compressed air motor.

ARTS AND INDUSTRY EXHIBITION AT MIDDLESBROUGH.—This Exhibition, which was opened on the 1st inst., has received an installation of the electric light, on the Brush system, put down by Mr. Goldston. The dynamo is driven from an 8 horse-power gas engine.

NEW TELEGRAPH STATIONS IN COREA.—The Great Northern Telegraph Company's telegraph system has been extended to Seoul, the capital of Corea, and to its port Ienchuan, Chemulpo, which two places are thus now in telegraphic communication with the rest of the world.

THE ELECTRIC LIGHT IN VIENNA.—At the half-yearly general meeting of the Imperial Continental Gas Association, held recently, the chairman, Sir Julian Goldsmid, Bart., stated that the association were making arrangements to light the Vienna Opera House with the electric light.

THE LIGHTING AT QUEEN'S GATE.—In the notice in our last issue of the small installation at 27, Queen's-gate, we mentioned that the designer of the chandeliers was unknown to us. We are now informed that they were manufactured and fitted up by Messrs. F. and C. Osler, of Oxford-street.

CATALOGUE.—Messrs. Woodhouse and Rawson send us a small pamphlet catalogue, containing interesting information about their make of incandescent lamps, besides the ordinary catalogue matter. In it they point out the direction in which they have been working in order to obtain practical and economical lamps.

ELECTRIC LIGHTING.—The Board of Trade has granted two licenses for electric lighting on a large scale. One of these licenses is granted to the Dalton-in-Furness (Lancashire) Local Board, for the district of Dalton-in-Furness; the other to Mr. John Edward Veale, for the district of the Austell Local Board (Cornwall).

LIGHTING THE SEWERS OF PARIS.—The question of lighting the sewers of Paris by means of electricity is under discussion. The project has been started by M. Guichard, a member of the Municipal Council. It is proposed to use Gramme regulators, supplied with current by the dynamo machines located in the Hôtel-de-Ville.

NAVIGATION OF THE SUEZ CANAL BY NIGHT.—Since the 1st instant, and until further notice, men-of-war and mail steamers furnished with the electric light have and will be allowed to proceed by night through that portion of the Canal comprised between Port Said and Kilometre 54, and *vice versâ*, subject to the regulations laid down by the company.

THE CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of November, 1885, was 2,707, estimated to produce £2,250, against 2,743 messages, producing £2,326, in the corresponding month of last year. The traffic receipts for the month of August, estimated at £2,200, realised £2,262.

OBITUARY.—The death is announced of Colonel Mangin, well known in connection with the electric projector which bears his name. Colonel Mangin was one of the few men who have laboured for science and for science alone.—We also regret to hear that Captain Trèves, whose recent researches have gained for him a well-deserved reputation in the electrical world, has also passed away.

LIGHTING OF A VILLAGE IN HOLLAND.—Messrs. Willem Smit and Co., of Slikkerveer, Holland, write to inform us that they have received an order to light up the village of Kinderdijk. The installation will comprise 400 sixteen candle-power Edison incandescent lamps and two self-regulating dynamos. The conductors, of about one mile in length, will be placed underground, and the existing lamp-posts utilised to carry the incandescents.

FIRE IN THE GENERAL POST OFFICE.—A few minutes before two o'clock on Wednesday morning some alarm was

Digitized by Google

caused by the outbreak of a fire in the basement on the north side of the General Post Office buildings. The firemen stationed in the establishment having discovered the seat of the fire soon managed to overcome it. When the smoke had cleared away it was found that the fire had originated in a basket of tools, which were almost consumed.

PROF. HUXLEY.—Prof. Huxley writes to *The Times* to say that his long connection with the Normal School of Science and Royal School of Mines at South Kensington is not at an end. At the request of the Lords of the Committee of Council on Education, he retains the positions of Dean and honorary Professor of Biology in that institution. It is stated that a pension of £300 per annum has been offered to Prof. Huxley, in recognition of his eminent scientific services, and that he has accepted it.

FORGERY BY A TELEGRAPH CLERK.—On the 26th ult., Frank Arthur Whitley, telegraph clerk, of Cradley, was committed to the assizes for stealing postal orders, the property of the Postmaster-General, and also for forgery. The prisoner sold two postal orders to a tradesman, which were posted in the prisoner's presence to a London newspaper office. The letter did not reach its destination, and subsequently it was ascertained that one order had been cashed at Birmingham, and that the prisoner had forged the order.

TELEPHONIC PROFANITY.—By permission of the Archbishop the Compañia Colombiano de Telefonos have been allowed to pass their lines through the church steeples in Bagotà, U.S. of Columbia, for which they come in very handy owing to their construction. In one church eight wires pass through the steeple, and the curate of the said church has thought fit to cut the wires twice in succession, giving, as his reason for this step, that they profane the church, telephones being a work of the devil.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The annual general meeting of this society will be held at 25, Great George-street, S.W., on Thursday, December 10th, at 8:30 p.m., for the election of council and officers for the ensuing year. The following papers will also be read:—"A Method of Eliminating the Effects of Earth and Polarisation Currents in Fault Testing," by Walter J. Murphy, assistant electrician E. and S.A.T. Co.'s ss. "Great Northern;" "A Method of Localising a Fault in a Cable by Tests from One End Only," by H. Kingsford, associate.

AN INTERESTING PAPER.—At a recent meeting of the New York Electrical Society, President Van der Weyde read a paper on a method of obviating the inaccuracy connected with the use of the differential galvanometer. He employs a double switch, by means of which he shunts the divided currents alternately into the opposite coils of the galvanometers, and then takes the mean of the two readings. He applies the same principle to the Wheatstone bridge, by alternating in the same way the relative position of the two fixed arms of the bridge. This suggests itself to us as being very much like Mance's method for the elimination of polarisation currents.

ELECTRICITY AND SHIPS' COMPASSES.—In an article contributed to the current issue of the *Nautical Magazine*, Mr. Bottomley is of opinion that the following points should be attended to in all cases of lighting ships by electricity:—With continuous current machines two wires, well insulated, should always be employed; the insulation of the wires should be tested periodically; if any connection with the iron of the ship is found, the fault should at once be made right; when an alternate current machine is used a single wire may be employed and the iron of the ship used to complete the circuit without the current producing any effect upon the compass.

SPECIAL RATE FOR PRESS MESSAGES.—The Anglo-American Telegraph Company inform us that, dating from 2nd inst., a special rate of 10d. per word will be charged for press messages containing political and general news for publication, expressed in plain and unabbreviated language, between the United Kingdom and New York and Canada. Press messages to be forwarded when the lines are disengaged will be charged at the rate of 5d. per word. Arrangements for the application of these reduced rates must be made previously, either at the accountant's office, 26, Old Broad-street, London, or with the agents of the company in the provinces.

THE PAVILION MUSIC HALL.—The new London Pavilion Music Hall, in Tichborne-street, Piccadilly, which has been erected at a cost, it is stated, of between £30,000 and £40,000, was opened on Monday last. Provision has been made for lighting the hall either by gas or electricity, and on Monday night the electric light was introduced with great effect. The building has been erected from the designs of Mr. J. E. Saunders, architect, of Finsbury-circus. Messrs. Peto Brothers are the contractors. The gas fittings and the machinery for the electric light have been supplied by Mr. Cannon, gas engineer, of London-road, Lambeth.

SOUTH WALES INSTITUTE OF ENGINEERS.—At a meeting of this institute held at Cardiff on Thursday, 19th ult., a paper on "Recent Improvements on Electric Light Apparatus," by Mr. Sydney Walker, was taken as read. During the course of a discussion which followed Mr. Massey stated that whereas three Victoria dynamos tested last year at Buckingham Palace were found to take from 42 to 49 horse-power to do a certain amount of work, very careful tests made recently showed that exactly the same work could be done for an expenditure of 37 horse-power in one of the newer Victoria machines; that two Crompton dynamos required 31 and 32½ horse-power respectively, and that an improved Siemens dynamo gave precisely the same electrical output with only 28¼ horse-power.

LLOYD'S PROVISIONAL ORDERS.—Application is intended to be made by the corporation of Lloyd's in the ensuing session of Parliament for an Act to extend and enlarge their powers as regards the "collection, publication, and diffusion of intelligence," and to provide that the publication and diffusion of any such intelligence shall be deemed to be a privileged communication from them. By other clauses power will be sought for to authorise them to establish signal stations and to erect signal houses, with all requisite telegraph and telephone wires, appurtenances, &c., "at such places on the coast of Great Britain and Ireland and the islands appertaining or belonging thereto as they shall think fit, and to maintain and work the same," such powers, however, together with the taking of lands or houses for the purpose, to be exercised only with the approval of the Board of Trade.

THE ELECTRIC LIGHT AND THE ADMIRALTY.—The Admiralty have solicited the opinion of the dockyard officers at Portsmouth, as the result of the experience of the yard with respect to the best method of dealing with the internal electric lighting of Her Majesty's ships. They are desired to state in their report whether it is preferred to continue the present system of placing the work in the hands of contractors, or to arrange in future for the performance of all the electrical work in ships by the dockyard *employés*, making separate contracts for all the material that may be required, in which

Digitized by Google

should be embodied the proper conditions for testing before receiving the several items. The officers are also required to state what number of workmen and leading men is considered to be a proper staff for the Portsmouth yard, and what number of assistant constructors for electrical fittings they think can be usefully employed at Portsmouth and at each of the other yards.

EARTHQUAKES.—It is reported from Victoria, Australia, that the earthquake shock felt at Albury was confined entirely to the north-eastern district of Victoria. It was felt at Bright, Omeo, Beechworth, and Tallangatta distinctly.—Several great earthquake waves from the Pacific were observed at San Francisco on Thursday between 1 and 8 p.m., at intervals of 35 minutes. Besides the earthquake shocks which occurred recently at Velez Malaga, on the coast of the province of Malaga, there appears also to be some seismic disturbance on the opposite African coast, giving rise to landslips of considerable magnitude. The bed of the sea at the points affected is also reported to have risen. It is stated that the shocks of earthquake h .ve been observed at the following places in Western Switzerland:—At Sion, Gryon, Ollon, Nov. 15, 2:15 a.m.; Chevroux, south east bank of Lake Neuchâtel, Nov. 18, 9:25 p.m.; and Gondo, south face of the Simplon, Nov. 20, 5:45 a.m.

MEMORIAL TO THE LATE SIR WILLIAM SIEMENS.—A window, erected in the nave on the north side of Westminster Abbey as a memorial to the late Sir William Siemens, was unveiled on 26th ult. Before the ceremony, a gathering of the friends of the late Sir William, and of members of several engineering societies, assembled in the Jerusalem Chamber, where addresses were delivered by the Dean and Sir Frederick Bramwell. A procession was then formed and entered the nave, where the ceremony of unveiling was performed. The window is designed to set forth the sanctity of labour, and at the base is inscribed, "In Memory of Charles William Siemens, Knt., D.C.L., LL.D., F.R.S., Civil Engineer. Born 4th April, 1823; died 19th November, 1883. Erected as a tribute of respect by his brother engineers." After the unveiling, prayer was offered by the Dean, and the proceedings closed with the playing by Dr. Bridge of "The Heavens are Telling," from Haydn's "Creation."

WEST AFRICAN CABLES.—It is announced that telegraphic communication has been completed between St. Thiago, Cape de Verd Islands, and various ports on the West African coast, thus connecting Europe with the Portuguese possessions, Bulama and Bissao, and the French settlement at Conakry, about eighty miles north of Sierra Leone. These stations, we are informed, will shortly be opened for traffic, the routes being *viâ* Cadiz or *viâ* Lisbon. The first of these will be through the Direct Spanish Telegraph Company's cable, the Spanish Government land lines, and the cables of the Spanish National Submarine Telegraph Company. The second is through the cables of the Eastern Telegraph Company and those of the Brazilian Submarine Telegraph Company. We strongly advise that the latter of these routes be chosen, for the reason that telegrams passing over the land lines of the Spanish Government invariably reach their destination in a mutilated condition. In connection with the West African cables, we may mention that Mr. March Webb returned from Praia, St. Thiago, on Wednesday last, having completed the staff arrangements and handed over the new lines of the company to Mr. Parsone, the resident manager.

THE WASHINGTON MONUMENT.—The improved arrangement for protecting the Washington Monument from lightning are now approaching completion. On the lower part of the aluminium pyramid which terminates the shaft has been fitted a collar, from which project eight 3in. metallic rods. To the corners of this collar four copper rods, about ½in. in diameter, are secured, extending down the edges of the pyramidal apex. These are joined together at a number of points along their length by horizontal strips of metal. All are securely joined to the corner or edge rods; and along both horizontal and edge rods metallic points will project at right angles to the rods, and at distances of 4ft. or 5ft. from each other. From the base of the small aluminium pyramid a thick copper rod extends to the capstone, and from the extremity of this rod four rods of copper, each having a diameter of ¾in., proceed downward, and are led to the four middle piers of the iron structure which carries the elevator and the stairway. At the bottom the earth connection is made by four heavy copper rods, which project several feet into a well of moist sand, at the bottom of which water is always standing.

THE TELEGRAPH IN CHINA.—According to *Nature* telegraphs in Southern China are extending with rapidity. Pekin in the far north is connected by a direct line through Canton with Lungchow on the frontier of Tonquin, the extension from Canton to the latter place being made during the recent war, purely for military purposes. Thus we have one great line stretching through the Chinese Empire from north to south, and at the present moment a line is being constructed along the southern borders of China. Starting from Nanking in Kwangsi, where it joins the Canton-Lungchow line, it will extend for nearly 600 miles to Mung-lih in South Yunnan. The work is being carried out by the Chinese themselves with the assistance of one European, and it is stated that during the recent war the Canton authorities equipped a complete field telegraph staff, the members of which were so thoroughly trained that they have been able to put up thirty-five miles of line in a single day for war purposes. Telegraphs have now secured a firm footing in China, and their extension over the the whole country is a matter of time only, aided perhaps by political events. In the great movement towards a centralised government now progressing in China the telegraph line will play a vital part, as it will utterly destroy the semi-independence of the provincial viceroys, hitherto secure in their remoteness from the seat of government.

THE TELEPHONE IN PARIS.—It is announced that telephonic communication between Paris and Rheims was opened to the public on Tuesday last. The distance is 172 kilometres, but the electric resistance to be overcome between the two points is estimated at 217 kilometres. The ordinary telegraphic wire is utilised for the purpose, but there is a special telephonic station in the Plain of St. Denis, at the Pont de Soissons. The tariff is one franc for five minutes' conversation. At the inaugural *séance* held on Monday night conversations were held with sundry public functionaries at Rheims, whose voices were heard with perfect distinctness. In a leading article upon this subject the *Standard* says: "Conversation has been held in America between two people separated from each other by over 410 miles. In Persia it has been effected between Tabreez and Tiflis, 390 miles apart; in India over a distance of nearly 500 miles; and in Australia words could be perfectly made out when transmitted along a wire 300 miles long. But in all of these instances the feat was accomplished either at night or under exceptional circumstances, and in every case the wires were underground. Had they been overground or submarine the result would have been different. Conversa-

Digitized by Google

tions have been held between Dover and Calais, between Dartmouth and Guernsey, and between Holyhead and Dublin. But there is no case where any persons had spoken through more than 100 miles of submerged cable."

THE INDIAN TELEGRAPH SERVICE.—The officers of the Indian Telegraph Department whose grievances in respect to promotion, pensions, and general treatment we commented upon in our leading article of 9th October, have been energetically continuing their efforts both in India and in England to obtain a thorough investigation of the subject. A strong committee has been formed, and has already received such powerful support that the attempt to intimidate it from official headquarters will almost certainly fail. It seems that the Director-General of Telegraphs in India has refused to receive any appeal coming to him in the form of a joint memorial or combination, as contrary to the rules of the service. But the committee have issued an assurance to its supporters that it fully understands the orders of the Government on this point, and has no intention of disregarding them. These orders, however, do not extend to communications addressed to members of the English Houses of Parliament, and as the Indian Government official responsible for the Telegraphs of India will neither redress individual wrongs nor listen to any statement of them in bulk, the aggrieved officers have determined to approach the ears of Government officials at home. We cannot blame them for taking this course; for it is only in this country that an acknowledgment is likely to be extracted that a gross miscalculation was made some years ago as to the requirements of the Telegraph service of India. This acknowledgment once obtained, probably there will remain, even in India, no difficulty in obtaining a confession that some sweeping measures of redress to the victims of official error are urgently needed. We notice that the Committee has reprinted our article above referred to, but that exception is taken to some remarks in the third paragraph of it, which the Committee intends to reply to in detail.

THE LATE HENRY FAWCETT.—In the "Life of Henry Fawcett," by Leslie Stephen, recently published by Smith, Elder and Co., the following interesting account is given of the sad accident which deprived him of sight:—"On September 17, 1858, Fawcett went out shooting with his father upon Harnham Hill. Harnham Hill commands a view of the rich valley where the Avon glides between the great bluffs of the chalk downs and beneath the unrivalled spire of Salisbury. It is one of the loveliest views, as Fawcett used to say, in the south of England. He now saw it for the last time. The party was crossing a turnip field and put up some partridges, which flew across a fence into land where Mr. Fawcett had not the right of shooting. In order to prevent this from happening again, Fawcett advanced some thirty yards in front of his party. Shortly afterwards another covey rose and flew towards him. His father was suffering from incipient cataract of one eye. He therefore could not see his son distinctly, and had for the moment forgotten their relative change of position. He thus fired at a bird when it was nearly in a line with his son. The bird was hit by the greatest part of the charge, for it was 'completely shattered.' A few pellets, however, diverged and struck Henry Fawcett. Most of these entered his chest, but, passing through a thick coat, only inflicted a trivial wound. Two of them went higher. He was wearing tinted spectacles to protect his eyes from the glare of the sun. One shot passed through each glass of the spectacles, making in each a clean round hole. Their force was partly spent, and was further diminished by the resistance of the spectacles. They might otherwise have reached the brain and inflicted a fatal injury. As it was they passed right through the eyes, remaining permanently embedded behind them. Fawcett was instantaneously blinded for life."

THE LIGHTING OF THE CITY.—At a meeting of the City Commissioners of Sewers, held on Tuesday last, at the Guildhall, Mr. Altman, chairman of the Streets Committee, brought up a report on the question of electric lighting in the City. They stated that they had for some time past had before them the question as to the desirableness of the Commissioners undertaking the supply of electricity, and, although it appeared clear that under the existing enactments the Commissioners could not advantageously do so, except for public purposes, they were still considering whether it might not be advisable for the Commission to make an installation of electric lighting upon a small scale; but the question needed further examination before they could submit a scheme for approval. They had also had under consideration proposals of the Anglo-American Electric Light Corporation, who for some years past had been lighting the line of thoroughfare extending from King-street, Cheapside, to Blackfriars Bridge, for continuing such lighting and extending the area, it appearing that, if the lighting was to be longer maintained, the cables must be renewed and installed in a more permanent and trustworthy manner than at present, which the company were not prepared to undertake except under conditions protective of their interests. The latest proposal of the company they regarded with some favour, but there were various matters of detail requiring further consideration before they could submit it for the approval of the Court. In the meantime they placed before the Court various reports upon the subject of electric lighting which had recently been made to them by the engineer, and they recommended that the same should be printed and circulated for the information of the Commissioners.—Mr. Altman moved the adoption of the report, which was passed unanimously.

THE INSTALLATION ON THE SS. "INVICTA."—Much has been said and written of the difficulties attending ship lighting, but nowhere are those difficulties more prominently noticeable than on board Channel steamers, where the engines driving the dynamos are frequently started and stopped, bringing heavy strains to bear upon both machinery and lamps. The rough and choppy seaway also necessitates the use of an incandescent lamp holder that will neither tear away the loops nor easily break contact. The installation on the ss. "Invicta," belonging to the London, Chatham, and Dover Railway Company, was, our readers will remember, put down by Siemens Bros. It consists of two Siemens dynamos, coupled direct with two Brotherhood engines of 8 horse-power, nominal, two 500 candle-power arc lamps for lighting up the quays when entering or leaving port at night, and about 95 Edison-Swan 20 candle-power incandescent lamps distributed as follows:—In the state saloon there are seven lamps in ground glass globes and pretty fittings, and in the companionway a group of three; over the engine room there are seven in a cluster, and in the ladies' saloon ten lamps in pairs and three single ones. The deck cabin fittings are ingeniously arranged, a hole having been cut in the partition wall of each cabin and a lamp inserted in a suitable outer globe, so that one lamp lights two compartments. Ten lamps are so arranged. In the general saloon there are two clusters of four and three respectively, and three single lamps on each side; the dining room is fitted with two pairs, a cluster of three and one single lamp; and a total of twenty-five lights are arranged in the engine room. Others are variously placed about the decks. One set of machinery feeds 75 incandescents,

Digitized by Google

and the other supplies current to one 500 candle-power arc and, if required, 25 incandescents. Except in the case of the arc, which has an independent metallic circuit, the steel frame of the ship is used as the return or earth, and, as need scarcely be mentioned, with good results. The installation is under the care of the chief engineer, Mr. Huddle.

RAILWAY CARRIAGE LIGHTING.—A correspondent to *The Times* of Thursday last makes the following remarks upon the important subject of railway carriage lighting:—"The article in *The Times* of the 19th ult. justly complains of the very indifferent way in which many railway carriages are lighted at the present time notwithstanding that an efficient electric light has now been in use for at least two years; but if the question is closely examined much of the surprise at the backwardness in applying this system to railway carriages will disappear. This particular system is now in regular use on two trains on the Brighton and one on the South-Eastern lines, a dynamo being worked in each case from the axle of the guard's van while the train is running, the electricity thus generated being stored in accumulators and used as required. Those who have had the management say this method of lighting is perfect, and after two years' trial not a hitch has occurred, nor has any reparing been needed, and these railway companies will, it is expected, extend the system, as it is both cheaper and more effective than any other. Methods of lighting by compressed gas, &c., are undoubtedly superior to oil, and when the use of electricity and gas is fairly introduced oil lighting must disappear. The advantages in favour of the electric light as compared with gas consist in the superior quality of the light and its being always ready for use when a train enters a tunnel in the day-time. The complaint at present is that the trains lit by electricity or gas must be 'block trains'—*i.e.*, must not be broken up, and other carriages not fitted for electricity or gas introduced between those so fitted. This may be a disadvantage at first, but when all the carriages belonging to a line are fitted for one or other of these systems this difficulty disappears. After a favourable report of the Board of Trade, and two years' successful working of electric light in railway carriages, the time has gone by for further delay or further trials, only it unfortunately happens that many railway companies have their own theory and system, and this is the chief cause of the delay in the general adoption of train-lighting by electricity."

THE ELECTRIC LIGHT IN GLASGOW.—Some months ago the directors of the Caledonian Railway Company, having decided to substitute electric for gas light in the company's Central Station, at Glasgow, requested Mr. S. Dunn, the company's telegraph engineer, to carry out the necessary arrangements. The installation comprises a 70 horse-power nominal horizontal steam engine, two No. 7 Brush dynamos with laminated armatures, and two small Gramme machines, all driven by composite (canvas-gutta-percha) belts, manufactured specially by Messrs. R. and J. Dick, of Glasgow. The Brush machines each feed 25 arc lamps of 2,000 candle-power, and the Grammes one each of 3,000 candle-power; 45 of the lamps fed by the Brush machines are suspended within the station, three are in the booking hall and two in the verandah. The two arcs of 3,000 candle-power light the shunting yard outside the station. The lamps within the station are hung on pendants, and are placed about 25 yards apart, and 15ft. in height, along the centre line of each platform. From the Brush machines the conductors are seven No. 15 S.W.G. strands of highest conductivity copper, insulated and braided, and these have been led round all the platforms, the object being to divide the lamps fed by each machine equally over the whole station. Should it, therefore, be necessary at any time to reduce the lighting of the station by stopping either of the machines, half the lamps, *i.e.*, every alternate one, will be kept going by the machine left in operation. The lamps are of 16-hour Brush pattern, with improved winding, polished brass cases, and are fitted with alabastrine globes, wire protected. The effect, when lighted on Monday, 23rd ult., was exceedingly pretty, great steadiness and brilliancy being obtained throughout the installation. A small horizontal engine of 12 horse-power nominal has also been provided to drive an Edison-Hopkinson dynamo, feeding 200 incandescent lamps, for the Station Hotel. Most of these lamps are fitted up in the lower portion of the hotel, and are therefore required during the daytime. The small engine runs the machine while lighting is not required in the station; but by a special clutch arrangement the driving is taken up by the large engine as soon as it is started for the lighting of the station. Both engines were built by Mr. John Bennie, of the Star Engine Works, Glasgow.

THE QUEENSLAND TELEGRAPH AND TELEPHONE SYSTEMS.—According to a report of the Post and Telegraph Department of Queensland for the year, 1884, which has recently been issued, the revenue derived during that year from the telegraphs was £77,118. 2s. 6d., as against £70,583. 14s. 3d. in the previous year; an increase of £6,534. 8s 3d. The usual return shows that on the 31st December, 1884, there were 1,511 persons of all classes employed by the Post and Telegraph Department. The number of telegraph messages in 1874 was 311,246 transmitted and 33,867 received, while in 1884 it was 1,006,184 transmitted and 110,298 received. The revenue from telegraph messages in 1874 was £21,396. In 1874 there were 4,891 miles of telegraph wire, and in 1884 11,299¾ miles. The report of the superintendent of electric telegraphs, Mr. A. F. Matveieff, concerning the telegraph branch for 1884, states that since the last report the extensions have been as follow:—Miles of line, 338½; miles of wire, 640¼. Besides some 600 miles of line which are in course of construction there are now 7,138¼ miles of line and 11,579 miles of wire open for public business in the colony. Cables have been laid between Lytton and the Pile Lighthouse, also across the Brisbane River near the lower magazine, connecting Lytton with Brisbane by a line along the north side of the river. A cable connecting Woody Island with Fraser's Island will probably be laid before long. No faults have shown themselves in any of the submarine lines since the last report. The duplex wires have worked throughout satisfactorily. Quadruplex instruments have been received, and after having been tested arrangements will be entered into for working the quadruplex system between Brisbane and Sydney. The four telephone exchanges at Brisbane, Maryborough, Rockhampton, and Townsville, respectively, have been working on the whole well. At Brisbane there are now 287 subscribers, Maryborough 57, Rockhampton 45, and Townsville 51. These numbers include Government offices, several of which are connected. Such offices pay no rent, nor do they in any way contribute to the expense of the Exchange. In Brisbane 42 such offices are connected, being about one seventh of the whole number of subscribers. At Maryborough there are 6, and at Townsville 3, free telephones connected with the Exchanges. A mile of aerial cable containing 25 wires has been procured, and will shortly be tried. If not liable to damage through the intense heat of the summer the number of wires in the streets can soon be considerably decreased, or, rather, the same number carried to their destinations in a much more compact manner.

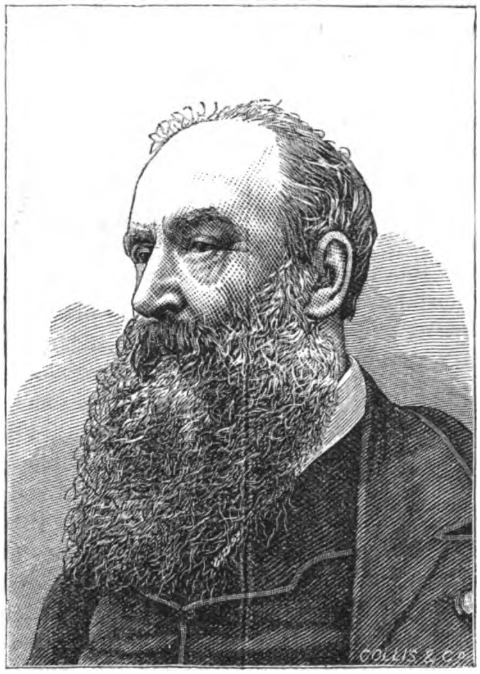
FREDERICK CHARLES WEBB.

WEBB, FREDERICK CHARLES: Born on the 1st of October, 1828, at No. 14, Surrey-square, Old Kent-road, London. He is the son of the late Mr. George Webb, formerly Secretary to the London Stock Exchange, who married Susanna, daughter of Thomas Bish. He received his early education at a private school at the Mansion House, Hammersmith, being afterwards placed at the Ecole Normale, at Brussels. Having learned French there he afterwards studied geometry, trigonometry, and navigation under M. Verhaart, Professor of Mathematics at the School of Navigation at Ostend; was placed for two years at the establishment of the Rev. Edward Jenkins (Chaplain to the King of the Belgians), at Brussels, where, amongst other subjects, he learned free-hand drawing and water colours, mechanical drawing, and fortifications. At the age of 15 he joined H.M.S. "Porcupine," a surveying ship, commanded by Capt. Frederick Bullock, R.N., but held no position in the navy (except for a short time when he was rated as a clerk's assistant), the object being to qualify him as a marine surveyor, so that on his obtaining a naval cadetship, which Capt. Bullock hoped to procure for him, he might at once receive the extra pay granted to the officers employed as surveyors. He was thus engaged for two years doing duty as a surveying officer, &c. During the two years he was in H.M.S. "Porcupine" the survey known as "The Downs," which includes the Goodwin Sands, was completed, and the free hand sketches of the leading marks, &c., were done entirely by Mr. Webb. He was also present at the erection of one of Captain Bullock's safety beacons on the Goodwin. The survey of the "Approaches to Harwich" was also completed whilst he was in the "Porcupine." Having waited and worked patiently for two years without pay, and not having sufficient interest to obtain a cadetship, he at last gave up the attempt, and the railway mania of 1845 breaking out he left the "Porcupine," and, under Mr. John Player, was engaged on the levels for the London, Newbury, and Bath Direct Railway. He was then placed with Mr. James Walker, of 23, Great George-street, engineer to the Admiralty, Trinity Board, Commercial Docks, &c., and was in that office grounded in all the duties of a civil engineer, such as drawing, tracing, taking out quantities, estimating, &c., and during the time he was with the firm the works in hand were the improvement of the Bedford Level drainage, the Admiralty Pier at Dover, the harbour of refuge at Alderney, St. Hilier's Harbour, improvement of Dover Harbour, improvement of Kurrachee Harbour, a new lantern to Eddystone Lighthouse, and other work. A particular manner of placing the supports of the roof, suggested by Mr. Webb, was approved, and adopted on the Eddystone, and in several other lighthouses. During the time he was with the firm he took the soundings for the contract drawings for the Admiralty Pier at Dover. He also made the whole of the surveys for the harbour of refuge at Alderney, and set out the two miles of railway from the quarries to the breakwater. After two years he parted from the firm, but was soon afterwards engaged for them in the surveys and levels of the Bedford Level drainage, on which work, as the gradient of the drains was to be only a fall of two inches to the mile, the levelling had to be very accurate. In 1850 he was introduced to Mr. Edwin Clark, then just appointed engineer to the Electric Telegraph Company. Mr. E. Clark engaged Mr. Webb as his assistant not only for the telegraph work, but as his own draughtsman for wrought iron bridges, and Mr. Webb drew out, under Mr. Clark's superintendence, the first iron bridge that Mr. Clark designed in London, and this was the first of the numerous bridges which that eminent engineer designed year after year. Mr. Webb soon, however, became engaged solely in the telegraph work, and executed the following:—The making of a complete set of surveys of the London street wires, of which no record had previously been kept; the erection of two wires between Brighton and Newhaven; six wires between London and Peterborough and two on to Grimsby; some 10 wires on the North London Railway; the surveys of the Lancaster and Carlisle, Maryport and Carlisle, and Stour Valley Railways. In 1853 the Electric Telegraph Company determined to lay cables to Holland, and Mr. Webb was appointed assistant engineer to the International Telegraph Company, the company formed to carry out this work.



Particulars of some of Mr. Webb's work whilst acting in the capacity of assistant engineer to the International Company have already appeared in our columns; but he also erected four wires between The Hague and Amsterdam, with underground wires in each of these towns. He acted as assistant to Mr. E. Clark in laying the cables across the Irish Channel, and laid them across the Firth of Forth, the Tay, the Solent, and the Humber, and for four years had the charge of the repair of all these cables. At one time, when it was considered dangerous to employ a steamer on the Dutch coast, as the ports were frozen, he repaired the cable in a Dutch fishing vessel, at a distance of thirteen miles from the coast. In 1857 he was engaged as one of the four engineers for the first attempt to lay an Atlantic cable; and he superintended the shipping of the "Agamemnon's" half at East Greenwich. The cable was, however, broken from the "Niagara," and Mr. Webb played only a negative part in that expedition; but he fitted up the "Leipsic" for picking up some of the lost cable.

In 1857 he helped Mr. R. S. Newall to complete the Bona and Cagliari cable, which had run short off Cape Spartivento, and to lay the cables between Cagliari, Malta, and Corfu.

In 1858 he and Professor Jenkin fitted up the "Elba," belonging to Messrs. Newall, Liddell, and Gordon, and, under Mr. Liddell, recovered some cables in the Mediterranean.

In 1859 he repaired the Dover and Calais cable, also the Cagliari and Malta cable, the fault in the latter being about half way between those two ports. In the same year he was engaged on the experiments made at Gloucester-road for the joint committee appointed by the Board of Trade and the Atlantic Telegraph Company, and during this time had the honour of showing to Faraday the "coil current," or, as it was for some time called, "Webb's current."

He also tested and reported on the 1858 Atlantic cable as regards the distance of the fault. His report showed how the resistance of the fault could be roughly ascertained by the *change in its resistance* caused by sending a negative current after sending a positive, a process which has since received

Digitized by Google

the attention of many electricians. In the same year he was deputed by the directors of the Red Sea and India cable to test the sections between Aden and Kurrachee, and received on his return the thanks of the Board for "his full and interesting report."

In January, February, and March, 1861, he was engaged in the "Resolute" tug in trying to repair the Emden cable. It was a very severe winter, and the cable being deeply sanded up, Mr. Webb failed to repair it. The work was continued in April, May, and June under Mr. Frances's management, and finally repaired in June.

In this year he contracted with Messrs. Glass and Elliot to find the labour and his own services for laying the Isle of Man cable, the first cable having Latimer Clark's outer serving, and he carried out his contract.

Submarime telegraph work had been slack for several years, and Mr. Webb found occasional work in levelling for parliamentary surveys of railways. In December, 1862, he joined as chief the engineering staff of Messrs. Sir Charles Bright and Latimer Clark, who had just been appointed engineers to the Indian Government, under the late Lieut.-Colonel Patrick Stewart, for the making and laying of the Persian Gulf cable. In this capacity he had charge of the testing at Mr. Henley's works, and also fitted out the five sailing ships, and the repairing ship "Amberwitch"; acted as chief of the staff on laying three of the sections, and had entire charge of laying the fourth. He was then engaged by the Indian Government, on the recommendation of Colonel Stewart, to remain out for one year in "Engineering Charge of the Line," to teach the staff to repair the cable, to complete some of the work, and to design proper premises for the storage and repair of the recovered cable. These works were carried out by Captain Mereweather, R.E., and have given entire satisfaction. Mr. Webb came home from India in 1865, and tried in vain to obtain employment on the 1865 Atlantic Expedition. He consequently took again to levelling, and he executed work for Mr. John Fowler on several lines.

His friend, Mr. Zerah Colburn, started about this time the paper called *Engineering*, and Mr. Webb, who had previously contributed to the *Engineer*, was solicited by Mr. Colburn to write leaders for the new paper on electrical matters. He has been a contributor to that journal at various intervals ever since.

In 1867 he had charge, on the part of the contractors (the India Rubber, Gutta Percha, and Telegraph Works Company), of laying a cable from Havanna to Key West (Florida), and from Key West to a lonely place called Punta Rossa, 120 miles up the Gulf of Mexico. He ran a little out of course in laying the cable across the Gulf stream, and then the expedition was attacked by yellow fever, and fifteen out of sixty perished. On his return to England he found that a pamphlet to his detriment had been circulated by an eminent scientific man, and as the Board of Directors refused an inquiry, he had no option but to bring an action for libel against the author of the pamphlet, on which counsel agreed that an apology should be made provided each party paid his own costs; and an ample apology was accordingly tendered.

In 1868 he was engaged in fitting out the ships for the second Persian Gulf cable, recovering sixty miles thrown overboard from the "Calcutta," and taking all the rest of the cable out and re-shipping it, and received the thanks of his Excellency in Council the Governor of Bombay. An estrangement between the India Rubber Company and Mr. Webb lasted for a year, when Mr. Webb was again employed, and laid the present Post Office cable between Holyhead and Howth, when he received Lord Spencer, the Lord-Lieutenant, on board the "La Plata." He also for the same company acted as second to Sir S. Canning in laying the Marseilles and Algiers cable, and repaired it, and recovered the whole of the cable laid during the Franco-German war between Cherbourg and Dunkerque. He laid the Direct Spanish cable between Bilbao in Spain and the Lizard, and repaired it two successive years. He also laid the Marseilles and Barcelona cable, and diverted the Direct Spanish cable during the Carlist war from Bilbao to Santander, where he was introduced to Marshal Serrano. In 1874 he was engaged by Messrs. Siemens Brothers to command an expedition to complete the Platino-Brazilliera cable, and recover 170 miles of cable out of the wrecked steamer "Gomos," and was then made a Knight Officer of the Imperial Order of the Rose by H.I. Majesty the Emperor of Brazil, who he had the honour of entertaining on board the "Ambassador." This was the last work he executed, but he was lately consulted by the Indian Government on the third Persian Gulf cable. In 1877 he was appointed electrician to H.M.S. "Vernon," the torpedo school ship; but his health failed him, and he had to relinquish the appointment, which was never again filled up. He is probably the only member of the Institution of Civil Engineers who has been entitled to R.N. after his name.

Besides his articles in *The Engineer*, *Engineering*, *The Electrician* (old series), the *Telegraphic Journal*—which he edited for about six months—and our own columns, Mr. Webb is the author of a paper "On the Practical Operations Connected with Paying Out and Repairing Submarine Cables," which was read to a crowded audience at the Institution of Civil Engineers on the 23rd of February, 1858. On this occasion Mr. Webb had the honour of sitting at the council table between Faraday and Robert Stephenson. He is also the author of several articles in the *Philosophical Magazine*, and of a narrative entitled "Up the Tigris to Bagdad," a copy of which was graciously accepted and gracefully acknowledged by Her Majesty the Queen. Some of his articles in *The Electrician* (old series) were republished in book form, under the title of "A Treatise on Electrical Accumulation and Conduction." In these articles he showed that induction takes place in a circuit which he has termed "the induction circuit" He patented a means of preventing the teredo from attacking the gutta percha of submarine cables, and showed how the ordinary sextant may be made to take larger angles. Several of these instruments, which were certified at Kew Observatory as taking 163 degrees, were made, and one was taken by Captain Charles Bullock, R.N., on his survey in Japan, as Captain Bullock perceived and declared that the improvement was of immense importance. He was made an Associate of the Institution of Civil Engineers in 1857, and promoted to membership in 1868, and on November 26, 1884, was by the Council, in consideration of the services rendered by him to the Institution, and of his long connection with it, enrolled as a life subscriber.

THE STEAM ENGINE INDICATOR.—XI.*

BY AMICE.

We may now turn our attention to diagrams from high-pressure condensing engines working with moderate and high ratios of expansion. For this purpose we shall deal first with an engine working with a boiler pressure of 30lb., and a maximum cylinder pressure of 27lb., and with steam cut off at about one-tenth of the stroke, as shown by diagram (Fig. 38.) The engine made 58 revolutions per minute, and with a mean pressure of 13·81b. obtained from the diagram shown, and its fellow from the other end of the cylinder, indicated 463 horse-power. Fig. 38 gives a mean pressure, as will be seen from the figures upon it, of 13·27lb. By following this diagram it will be seen that the steam was admitted in such a way as to give full pressure in the cylinder instantaneously. It fell a little during the short period of admission, and at about one-tenth the stroke steam was fully cut off, and pressure fell to atmospheric pressure before four tenths of the stroke had been completed, and continued to fall until a little below 3lb. per square inch. This would not usually be considered quite a sufficient terminal pressure, as the back pressure or imperfect vacuum represents rather more than 2lb. Deducting this back pressure from the final pressure of 3lb. a pressure of but 1lb. is left to overcome the friction of the engine; not a sufficient quantity if the view that the terminal pressure must, to produce good results, be enough to overcome engine friction as well as back pressure. We are, however, inclined to think that this view is not altogether correct. The period during which the pressure is below that necessary to balance back pressure and engine

* For Art. 10, see *The Electrician*, 27th November, 1885.

Digitized by Google

friction is very small, and it is not quite so certain that a loss accompanies expanding to pressures below that balance. It is difficult to see where the line could be drawn if terminal pressure is to be anything more than that necessary to balance back-pressure. We could not make it back pressure and friction, or we might next have to take in friction of belts and shafting. We should therefore, from our point of view, say that Fig. 38 is a good diagram representing good practice.

It is, we assume, unnecessary to give any further examples of diagrams, merely as pressure diagrams, of the use of the mean pressure obtained from them in calculating the indicated horse-power, so that we will in this case content ourselves with giving the diagram, with the pressures marked off. The diagram was taken with a spring which gave 16lb. to the inch, a scale which is suitable for the speed, but would not be stiff enough for higher speed.

It will be observed that this diagram (like Fig. 37, p. 47) is accompanied by a series of diagonal and horizontal lines. These we may at once say are lines which have been drawn as the means of obtaining graphically the theoretic expansion curve, and for obtaining the point of cut off when that is not known, or for assigning a point which shall give the point at which cut off would have to take place in order to produce the curve of the indicator diagram, supposing no steam to be undergoing expansion except that accounted for the stroke of the piston. There is, however, besides this an amount which is considerable admitted at every stroke to fill up clearance and port spaces, and this amount appears in the after part of the diagram, and gives a curve which appears to indicate a later cut off than is actually the case. This brings us to a consideration of the theoretical diagram of expansion.

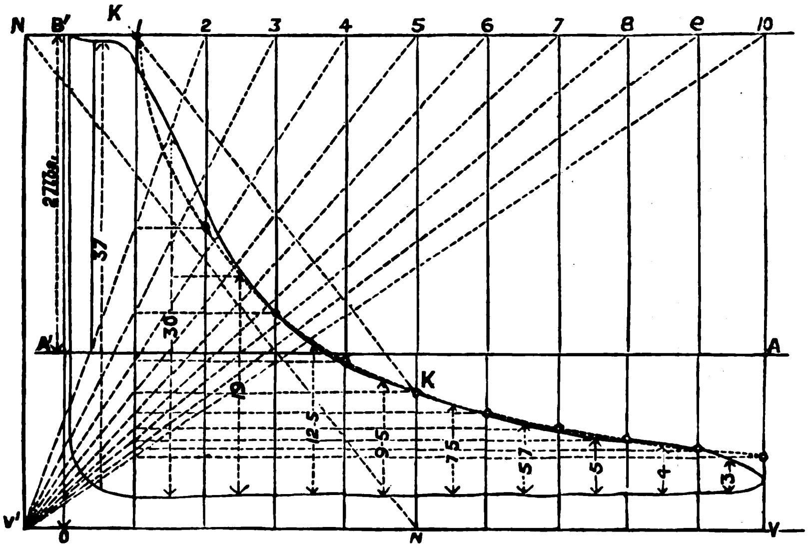


FIG. 38.

In engines of good design and in good order the steam pressure during expansion follows within narrow limits the curve drawn in accordance with Boyle's law, namely, that the pressure falls as the volume increases. The actual or indicator diagram curve falls more quickly at the commencement of the expansion than the law requires, but more slowly than it requires during the latter part of the expansion. This happens not to be so in Figs. 37 and 38 as regards the first part of the expansion, but it it is borne out by Fig. 37 as regards the latter part of the stroke, and will be shown more completely by diagrams to be given hereafter. Practically, the departure by a minus quantity at the beginning, and by an excess in the latter part of the expansion, makes the indicator diagram curve nearly identical in area with the theoretical or hyperbolic curve formed according to Boyle's law, and this is partly due to the steam admitted to fill clearance and port spaces, and partly to condensation in the beginning of the stroke. We shall therefore assume for purposes of calculation that the expansion of steam in a steam engine cylinder takes place according to this law, and that the curve representing the diminishing pressures due to increase of volume is a portion of a hyperbola. To the accidental reasons for the approach practically to the theoretic diagram, according to this law, although theoretically there are reasons why it should not, we shall refer hereafter, and will now proceed to the construction of the hyberbolic curve with a given base line. This we may do by calculation, or it may be done graphically, and as the former will afford some explanation of other matter as we proceed with it, we will take that first. Let

L = length of stroke in feet.

l = portion of the stroke during which steam is admitted, or the point of cut off, in feet.

s = any greater part of the stroke measured from the commencement in feet.

P = total initial pressure, *i e*, pressure in lbs. per square inch, including atmosphere.

P′ = total pressure in lbs. per square inch at end of a given part, s, of the stroke.

P″ = total final or terminal pressure in lbs.

L, l, and s may, of course, be taken in inches, but for convenience we will take them in feet, as given above.

Then the pressure at any given part of the stroke or

$$P' = \frac{P \times l}{s} \text{ or } P' = \frac{P'' \times L}{s}.$$

We have several times referred to the spaces not swept through by the piston, including the clearance between cylinder cover and piston and the steam ports. When dealing with a practical case the volume of this clearance must be reckoned in such terms as will enable it to be added to the period of admission of steam before cut off; for instance, if a cylinder be 100in. area, then each inch of the stroke of the piston will represent 100 cubic inches of steam, and cut off at one-fourth of the stroke, if the stroke be 20in., will represent 500 cubic inches, *i.e.*, with cut off at 5in. of the stroke. But, if the clearance between the end of the cylinder cover and the piston and the space in the ports, which it must be remembered has to be filled, be, say, 50 cubic inches, then the amount of steam admitted will be equal to the 500 cubic inches plus the 50 cubic inches, which makes the total quantity admitted equal to that which would enter during 5·5in. of the stroke, and this will of course affect the curve of expansion, although the 50 cubic inches of steam do no work during admission.

In the following example, however, we will assume that there is no clearance, and will return to an allowance for this hereafter.

In Fig. 39 let the base line $m\ n$ be the length of the stroke, say 6ft., $m\ c$ the initial pressure, say 63lb., $c\ d$ the period of

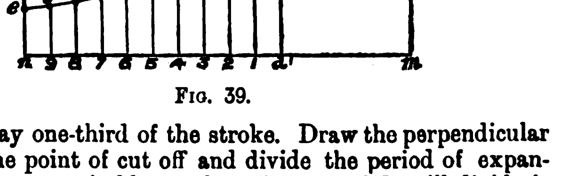

FIG. 39.

admission, say one-third of the stroke. Draw the perpendicular d, a' from the point of cut off and divide the period of expansion $d'\ n$ into any suitable number of parts. We will divide it into ten parts, as we have done in the case of the practical diagrams already given, and calculate by the first of the two of the above expressions the pressures at each of these divisions, 1, 2, 3, &c., and set them off by a scale of pressures on the vertical ordinates. The curve $d\ g$ traced through the ends of the ordinates is the hyperbolic curve of expansion. At the successive points of the base of the expansion line, each

Digitized by Google

of the divisions being $\frac{4}{10}$ths of a foot, the expansion part of the stroke being 4ft., the pressures so found will be as follows :—

$$\text{At 1 it will be } \frac{P \times l}{s} = \frac{63 \times 2\text{ft.}}{2 \cdot 4\text{ft.}} = 52 \cdot 5\text{lb.}$$

$$\text{At 2 it will be } \frac{P \times l}{s} = \frac{63 \times 2\text{ft.}}{2 \cdot 8\text{ft.}} = 45 \cdot 0\text{lb.},$$

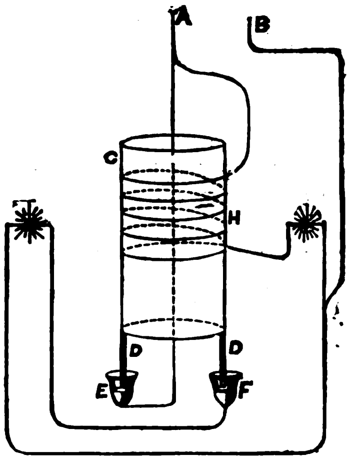
and so on for the whole of the ten pressure ordinates taken, or pressures at d',

	1,	2,	3,	4,	5,	6,	7,	8,	9,	n
are ...	63,	52·5,	45,	39·4,	35,	31·5,	28·6,	26·1,	24·2,	22·5, 21lb.

These pressures being set off on their respective lines, and a curve drawn through the points so marked off, we get the hyperbolic curve $d\,g$. Here we must leave the matter for another week.

AN AUTOMATIC COMMUTATOR.

M. Clerc, the designer of the Sun lamp, has quite recently designed a "shunt" for use in incandescent circuits where the lamps are in series. The coil H is wound round a cylinder of soft iron, C. The cylinder carries at its lower end the two contact pieces D D, which may or may not make contact in the mercury cups E F. The lamps as shown are in series. A and B show the line wires. When the right hand lamp is unbroken the current traverses the coil H, and through the lamp to B, while the action of the coil raises C and thus its



contacts, D D, out of the mercury. If, however, the lamp is broken, the circuit is completed through A E D, D left-hand lamp to B, and so the failure of the light is avoided.

THE ROYAL SOCIETY.

The anniversary meeting of the Royal Society was held at their rooms, Burlington House, on the 30th November. It will be unnecessary for us to dwell upon the admirable address of the President, which dealt most ably with the progress of science generally. Students of electricity will welcome the announcement that a Royal medal was awarded to Prof. D. E. Hughes, F.R.S., for his researches in electrical and magnetic phenomena. At the anniversary dinner the president, Prof. Stokes, mentioned the presentation of the Royal medal to Prof. Hughes, and proposed a toast to the recipient, to which Professor Hughes replied as follows :—

Mr. President, my Lords and Gentlemen : I cannot hope to find suitable words to express my thanks for the kind manner in which you have responded to the toast proposed by our president, Prof. Stokes, nor sufficiently thank him for the flattering terms in which he has mentioned my researches. The numerous experiments which led me to the invention of the microphone are based upon the discovery I made of the remarkable property of loose electrical contacts. If we make a bad joint or loose contact in an electric conductor, we find that not only do these disjointed conductors vibrate] in unison with the atmosphere, but in vibrating they produce an enormous variation in the strength of the electrical current. And if we join a telephone in circuit we find that every word spoken to the loose contact is repeated with absolute perfection. An equally remarkable fact is the reversibility of the effect, so that a loose electric contact will repeat in sound any variation of current passing through it ; consequently, we may speak to one loose contact and listen to a second, when every word spoken to the first will be clearly heard. The greatest power of sound, however, is obtained when used with a telephone, and the augmentation of sound is greatest when the original sound is most feeble. In order to study the effects of feeble sounds I at first listened to the ticking of a watch, and after making the microphone more sensitive, I was desirous of listening to sounds below the power of the human ear, such as those produced by the walking of a fly. This succeeded perfectly, but unfortunately flies were scarce at the time I was experimenting. I then studied sounds still more feeble, such as the sounds produced in a copper wire at each passage of an electric current—sounds which no human ear has heard direct, but which by the aid of the microphone are heard as a clear, ringing sound, due, I believe, to molecular motion in the wire itself. The microphone not only augments feeble sounds, but it will transmit the most complicated sounds of speech and music with absolute perfection. It has also been employed in physical, medical, and mechanical researches, and in France it has been of service to humanity in listening through the rocks to the sounds made by entombed miners, and by its indications encouraged the aid which finally saved them. The molecular sounds which the microphone revealed led me to invent an instrument which should penetrate inside of a metallic body, and reveal any change in its structure. This I accomplished in my induction balance. In this instrument induced currents from two separate coils are opposed and balanced with each other, but this balance of current is so sensitive that the slightest disturbance or reaction produced by the introduction of a piece of metal in one of the coils destroys the equilibrium. The amount of disturbance can be measured and the balance restored by the introduction into the second coil of a similar piece of metal, or by an equal reaction. If we could find two equal pieces of metal, such as coins, they would balance each other, but in practice the instrument is so sensitive that it points out differences in two similar coins fresh from the mint ; or in two pieces of equal weight cut off the same bar, due either to a slight chemical or molecular difference in the structure of the metal. Any physical or mechanical change, such as that produced by heat, magnetism, or strains, is at once declared ; and it is particularly sensitive to such changes in iron or steel. A curious example of its sensitiveness to iron occurred at the Paris Electrical Exhibition. Elisha Gray, the inventor of the harmonic telegraph, told me that fifteen years ago a small iron filing had penetrated his finger, giving at first some pain, but the filing and pain soon disappeared. He was anxious to know if the filing was still in his finger. I told him to place each finger successively in the induction balance, which he did, and all fingers gave perfect silence except one. This finger, however, immediately acted on the balance, producing loud sounds, and this finger proved to be the one which had been injured by the filing. So there could be no doubt that the filing still remained after a period of 15 years. If we place an iron bar or rod in the coils of the balance, we find that no two portions of the bar are exactly the same, and the slightest flaw, strain, or crystallisation of the iron is at once detected. Now, if we could apply this method to locomotive axles, we should be able to detect, in advance, any defect, and thus prevent the numerous accidents which occur on our railways from this cause. At present we cannot do this without first detaching the axle from the locomotive, but I hope some day of finding a modification of the balance which will overcome this difficulty. The electric sonometer aids the induction balance by comparing sounds from an absolute zero to any desirable extent, and it has been found most useful for measuring the power of hearing in those partially deaf. To cite a single example : Dr. Richardson, F.R.S., lately published an account of a youth who had been very deaf for many years. On being observed by the aid of the sonometer, the sonometer indicated that the cause of deafness was that of a solid obstruction, and upon operation a stone or pebble was found in the ear, which had been there unsuspected since childhood. On the removal of the pebble the hearing was immediately and permanently restored. I will not detain you by speaking of my researches in electricity and magnetism, nor of the many remarkable effects of the microphone and induction balance, but I am proud to say that all these instruments and researches were first presented to the world through the *Proceedings* of the Royal Society. I am deeply grateful to Dr. De la Rue for having on many occasions assisted me with his valuable advice, and allowing me to make use of his magnificent laboratory whenever the nature of my experiments needed such aid. Allow me to express my sincere thanks for the great honour conferred on me this day, and for the kind manner with which you have listened to my remarks.

NATIONAL STANDARDIZING.

Following the example of some distinguished men of Science who have lately advocated its endowment by the State, certain lesser luminaries are preferring the claims of particular branches of science to this pecuniary honour. Prof. Ray Lankester thinks that a suitable laboratory for the study of bacteriology should be equipped at once; and as the progress of bacteria concerns the commonwealth at least as closely as the courses of the stars, the endowment of a bacterial observatory is as much the duty of the State as the maintenance of the establishment on Greenwich Hill. Similarly, Dr. Fleming argues before the Society of Telegraph-Engineers that a Standardizing Institution for testing electrical instruments should be nationally endowed, because the yard measure enjoys this distinction at the same spot. Prof. Lankester, who is not an astronomer, thinks, perhaps, that the stars we have always with us, but not the cholera; whilst Dr. Fleming, who is not a bacteriologist, regards exact electrical measurement as the foremost want of the age, not excepting the true theory of germs. It is charitable to suppose that both these specialists, and others we could name, are in reality merely on the look out for pickings. Contemporaneous with the threatened dispersion of old endowments there is an independent outcry for endowments new; and consequently everything that wants to be endowed just now had better be quick and say so.

This is all very natural, even for scientists, though their logical consistency in this relation may not be scientifically square. But, to say nothing of the General Election, there are prejudices against endowments deep rooted in the English mind not likely to be overcome in a hurry. Establishments, theological and corporative, which are cited as precedents, are really not State endowments at all; and the same observation will apply largely to institutions of an educational and scientific kind, the sole conspicuous exception being one not very encouraging as an example to follow. Dr. Fleming admitted that a demand for the endowment of research was suspected of being an experiment in the research for endowment. Certainly this is what it might lead to, for it has done so already. And the worst of it is you cannot blame anybody for the consequences which necessarily follow when once the path of independent research is departed from. Every individual concerned is at first genuinely and disinterestedly anxious to promote the branch of study to which he is devoting himself; and national endowment is the most attractive means of promoting it. But scientists are human beings, and we should have liked to hear what Dr. Fleming's answer is to the suspicion above referred to. Does he doubt that anything of the kind would happen, or that it matters nothing if it did?

Be this as it may, there is a practical difficulty in the way. The endowment is not likely to be got; and those who are best acquainted with the probabilities of the case stated at the meeting that the mixing up of the two questions—a standardizing institution, and a national endowment of it—would greatly hinder the realisation of either. In other words, the desired tests might be had at comparatively small cost, part of which could be borne by establishments already subsidised by the State for national purposes; but that the creation of a national institution for promoting quantitative electrical research would be a costly affair which the nation would refuse to put its hand to. And this seems to us extremely probable. Apart from the general objections to endowments, which unless universal must be by favour, there would be no limit to the demand and no intelligible reason for refusal. Even if the funds of a particular branch of the public service, such as the Patent Office fees, as suggested by Dr. Fleming, were available, every other conceivable interest that is represented on the Patent Office register would have an equally cogent claim to a share. And having disposed of all the money in that quarter, what is to be said to the claimants who render great service to the world without ever going to the Patent Office? Anyone can easily reckon up a score or more of such "institutions" that might reasonably ask for State assistance if it were granted to one. It is usual, therefore, except in some exceptional undertaking of obvious national importance, and when no other resources can be obtained, to reject all applications of the kind; and we think that this rule will not be departed from in order to establish a national Standardizing Institution for the benefit of electrical science or industry.

So obvious are these considerations that we cannot help thinking that the warm support Dr. Fleming received for his general propositions was on grounds quite different from those on which he himself had based them. The truth is, as everybody knows, the electrical standard itself is in need of being standarized—at least, so the high scientists declare, and probably will continue to declare while there is a fraction of a fraction to higgle about. Hence the desire for further research—not a remunerative business—and the perfection of electrical standards. But the practical electrician cares

Digitized by Google

very little about these niceties, his chief concern being to be provided with some one place where his apparatus may be subjected to a test common to all. It matters not what the standard is so long as it is uniform, any more than it matters to the clothmaker what a yard is if only we are all agreed as to what its length shall be. Electrical measures have not yet attained any fixity, partly because experts are still disputing as to what it ought to be, partly because until now the practical necessity for decisive choice had not arisen. The dispute may go on indefinitely; but meanwhile the demand for a practical agreement has become urgent, and will not wait the establishment of an institution, national or private, for electrical research. Probably the Society of Telegraph-Engineers will for the present confine its action to the attainment of the less ambitious and more feasible of these two schemes.

CORRESPONDENCE.

DYNAMO MACHINES.—RATIO OF MAGNETISM TO MAGNETISING FORCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Several papers and notices have lately appeared which deal with the theory of dynamo machines. Two features appear to me to call for remark in these.

1. Fröhlich's formula is assumed to be a sufficient representation of the course of the ratio of magnetism to magnetising force.

2. It is assumed that it is possible to define the behaviour of a dynamo by means of considerations based only on the properties of the machine.

1. Now, Fröhlich's formula wholly fails to represent the truth for small magnetisms. In fact, the resistance to magnetisation has large values initially; it then diminishes as the magnetism increases, and ultimately increases again under the conditions known as "saturation."* Fröhlich's formula represents the saturation values fairly, but not the initial values. And it is clear that no theory of the starting of dynamos can be of any value which is not based on the correct representation of these initial values.

2. Wherever changes in the velocity of a dynamo are contemplated, as included in an investigation, it is clear that the governing function of the prime mover, or the relation between the velocity and the power afforded, is an essential element in the calculation. Thus, if an ordinary series machine be driven by an engine with a good governor at a uniform speed, the introduction of resistance into the circuit will rapidly bring the whole effect to nothing, whereas if the governor be removed, and the engine allowed to run at the higher speed natural under the diminished load, a compensation takes place, and an effect is maintained even against large resistances in circuit. Investigations in which no allusion to governing function is found cannot, therefore, give a complete account of the connection, for instance, between current and resistance in a dynamo machine.

I hope before long to apply the results of a series of experiments on the magnetic resistance of electro-magnets with pole pieces to the further elucidation of some of these questions, on the lines of my paper in *Phil. Mag.*, April, 1883, p. 275.—Yours, &c., R. H. M. BOSANQUET.

St. John's College, Oxford, December 1, 1885.

* Values for some bars may be seen in *Phil. Mag.*, 5th series, XVII., p. 532-4. In magnets with pole pieces the changes are of the same nature, but more prominent.

ELECTRIC HAULAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Feeling particularly interested in the subject of electric haulage, and reading an account of a novel system in your valuable journal, I venture to ask you for a few particulars to supplement those already given. I cannot, for instance, reconcile your statement as to the consumption of electric energy with the results of experience. From numerous experiments, corroborated by the best authorities on tramway matters, I believe that the pull required by a vehicle on tram rails is from 25lb. to 35lb. per ton at a speed of six to eight miles per hour on the level road. You say that the engine of the Electric Locomotive and Power Company weighs 4 tons 17cwt.; the speed obtained is said to be eight miles an hour. Taking an average of 30lb. tractive force per ton at a speed of 704ft. per minute, I get 3·11 horse-power, without allowing for any friction in the gearing and motor; now, there is a level wheel running at 700 to 100 revolutions per minute on a circular rack; the motor, which probably weighs 5cwt., swinging round at 80 to 100 revolutions, must involve a large amount of friction, however nice the teeth of the wheel and rack may fit, the tendency being to lift the motor shaft with a leverage of 2ft., and jam the vertical pivot underneath the motor, which works the mitre gear on the driving axle. A rough calculation, which I have made from well-known data, shows that there is at least 1·3 horse-power lost in friction, even if all parts fit well and are thoroughly lubricated. This would bring the power to 4·4 horse-power for the locomotive alone, on the level road. On a rise of about 1 in 45, which occurs often, and which we call a moderate incline, your modern "Archimedes" will find that he will have to expend over 10 horse-power in his engine without attempting to haul the car, full of people. A full car will weigh another $4\frac{3}{4}$ tons, and thus double the power required once more. You state that the power of the motor is 4 horse-power, and that it consumes 40 amperes per hour, with an E.M.F. of 100 volts in the battery. I am not quite clear as to what is meant by "40 ampere hours," and I should think that, with a full car behind the engine of your modern "Archimedes" will not run faster than two or three miles per hour and use up current at the rate of 70 or 80 amperes on the level road, and I cannot imagine how he will get over an incline. I have always heard that electricity might be made to work tramway cars as cheaply as steam, because no separate locomotive engine is requisite; therefore, less weight and less propelling force, the adhesion on the rails being supplied by the car itself and the weight of the passengers, and it seems to me that the Electric Locomotive Company is taking a retrograde step. What, we may ask, is the cost of hauling cars as described by you, inclusive of depreciation?—Yours, &c., H. S.

November 30.

A PHENOMENON OF CURRENT INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Reading a paragraph some days ago on Retardation in Mr. Sprague's *Electricity* (p. 80) I have derived a thought which leads me to believe that I have been reasoning in a diametrically wrong direction as regards what must take place in the induction coil. Assuming that the closed secondary circuit "relieved" the primary of a load as I suggested (p. 472, Vol. XV.), it would be relieving it only of *lateral* opposition, and not of any opposition in the path of conduction. This relieving process would be a kind of *yielding*, a yielding to electric force taking place not along the main path; it would, therefore, be a dissipation of the longitudinal tension. Such a yielding might be compared to the yielding of air in the air-chamber of a force-pump or in Dewar's spray-producer, in which examples the tension and discharge are moderated by the yielding, *while it lasts.* As regards the secondary wire influenced by induction, its yielding will, as I calculate, *more rapidly* terminate in equilibrium under each pulse of intermittent force when the terminals are joined than when they are insulated from each other. I regard the process of acquiring magnetism in the core as a similar lateral yielding. Until the electric force is balanced and checked in this direction, the action along the path of conduction must necessarily suffer. For my own part I find those considerations of *what work is being done*

Digitized by Google

merely tend to confuse and lead me wrong; so that I prefer to go all the way back to Newton's third law. But, perhaps, this is only saying that men cannot read with one another's glasses.

I still expect to find from experiment that the pulses of the primary have more effect on a galvanometer when the secondary is closed, on the ground of more speedily obtained equilibrium.

Yours, &c., E. ALDRED WILLIAMS.

37, Burlington-road, W., Nov. 28th, 1885.

CANDLE-POWER OF ARCS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the report which you publish on lighthouse illuminants the candle-power appears to correspond fairly with a formula which I devised to fit the tests of the Franklin Institute, viz., $\frac{1}{300}$th of the square of the watts. For example, an arc of 6,021 watts gave 11,000 to 15,000 candles.

The comparison of measurements of arcs, especially small ones, with this formula, would be of considerable interest.

This would give only 410 candles for a 10-ampere 35-volt arc, which is probably rather below the mark.—Yours, &c.,

Halifax, December 1, 1885. ALEX. P. TROTTER.

THE SOCIETY OF TELEGRAPH-ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is neither my duty nor my desire to enter into the vexed question which forms the principal subject of your article upon the society in your issue of the 27th ult., beyond saying that I trust the course which the council have adopted this year will satisfy those whom you state are at present discontented. But there are minor points touched upon in your article in respect of which you have been led into statements which are not quite accurate, and which you will, I am sure, permit me to correct.

1st. You complain that if precedent be followed there will be no notification of the fact that the annual meeting is fixed for December 10th from the official source until "a few days prior to the event," and that as regards the persons to be elected, their names will be posted "on the day of the annual meeting, or possibly the day before." As a matter of fact, the date of the annual general meeting is made known to members on the sessional card sent to them the previous January, and a special reminder, accompanied by the list of members recommended for election on the council, is posted, not the day before, but eight days before the meeting.

2nd. You base your assumption that the general body of members are apathetic on the subject of the election upon the small number of balloting papers "deposited in the sacred urn" on the evening of the election; but I can assure you that the "innocent young men," and the "case-hardened old ones," to whom you allude form but a mere fraction of the whole body who exercise their right to vote upon the occasion, the "sacred urn" being usually nearly full of voting papers which have been previously sent in by post or by hand.—

Yours, &c., F. H. WEBB, Secretary.

London, Dec. 1st, 1885.

ELECTRIC MOTOR ON THE NEW YORK ELEVATED RAILROAD.

Preliminary trials of a Daft electric motor, the Ben Franklin, have been in progress for some time past on a portion of the Ninth Avenue Elevated Railroad of this city, extending from 14th to 52nd Streets. The dimensions of the principal parts of this motor are as follow:—Driving wheels, 48in. diameter; trail wheels, 36in. diameter; length over all, 14ft. 6in.; spread of wheels, 5ft. 6in.; diameter of armature, 25in.; weight of armature, complete with shaft, 850lb. Total weight of motor, 8¾ tons. Ratio of armature revolutions to drivers, 1 : 5·5. Ratio of peripheral speeds of armature and drivers, 1 : 2·8 +. The reversing arrangements consist of four brushes attached, with compound levers and so connected that the direction of rotation must necessarily be that best suited to the proper contact and wear of the brushes. There is also abundant provision made for varying the points of contact in proportion to the load, speed, &c. The regulating switch consists of a sliding plate having metallic contacts arranged on its surface in such a manner that a number of spring contacts effect changes in the internal resistance of the machine, so as to regulate the speed without the use of idle resistances, none of which are employed; the highest economy is therefore obtained with light as with heavy loads. The electric brakes are of the pendulum type, which were first used on the Mount M'Gregor motor in 1883, and are connected with a switch conveniently arranged to vary their power by variation of internal resistances. The mechanical brake consists of a compound lever attachment operated by a screw shaft through a thoggle mounted nut. Contact with the third rail, placed between the main rails, is effected by means of a phosphor-bronze wheel attached to a movable framework, which can be raised and lowered, as occasion requires, by means of the lever shown in the side elevation, Fig. 1.

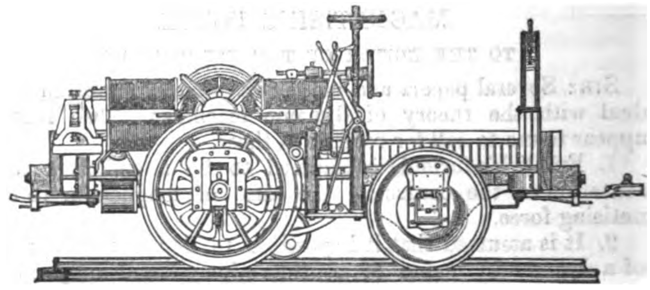

FIG. 1.—Side Elevation of the Electric Motor.

Upon each end of the armature shaft is a small wheel, formed with corrugations on its face which fit in corresponding corrugations on the face of a larger wheel mounted at each end of the driving-wheel axle. As will be seen by reference to the drawings, Figs. 1 and 2, the electro-dynamic machine is pivoted at one end in resilient bearings and attached to a vertical screw shaft at the other end, so as to enable the operator to vary the frictional contact between the friction gearing at will, and also affording an easy and convenient means for raising the whole machine to effect a change of armatures.

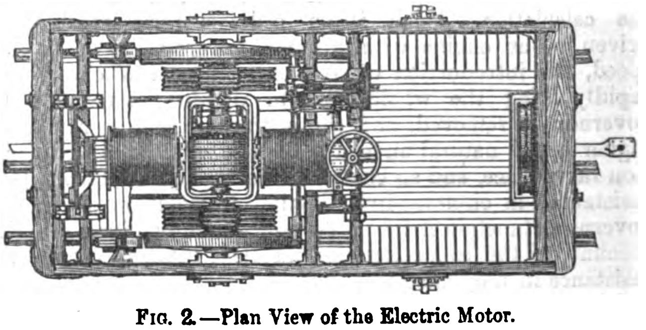

FIG. 2.—Plan View of the Electric Motor.

In order to avoid damage to the gearing and other parts of the electro-dynamic machine from shock, the whole machine is maintained in about equal resilience by means of alternating laminæ of iron and india rubber placed over the bearings of the drivers in lieu of the ordinary springs, and again in the pedestals at either end of the electro-dynamic machine. The object of using these laminated cushions is to avoid the too considerable motion which would result from the use of the ordinary springs, and at the same time provide a degree of resilience which enables the machine to run over very rough roads without the least derangement of parts.

The cab contains also a voltmeter, which shows the engineer the difference of potential on the track, just as the ordinary pressure gauge now indicates the pressure in a boiler.

Digitized by Google

The rails are the ordinary 56lb. steel rail, insulated by means of the Daft insulator, which consists of an umbrella of cast iron, with head so formed as to readily admit of locking the base of the rail by means of two cap screws and washers. The standard is formed of any suitable insulating material; the standard now in use on the elevated road consists merely of baked hard wood saturated with asphaltum, which has so far been found to afford ample insulation for all practical purposes—the leakage with four miles of track now involved (two miles of double track), plus the switches, being inconsiderable. The joints are made by drilling holes in the web of the rails, and riveting strips of copper from one to the other; this method has been found entirely satisfactory both here and on the road now in operation in Baltimore—the resistance being thus reduced to nearly the calculated line resistance.

No difficulty has been experienced in making the switches, though in some instances a considerable interval has to be bridged by momentum alone, due to the necessity for leaving out the third rail in order to permit the passage of the ordinary steam locomotives; this difficulty would of course be removed in the event of the entire road being operated electrically. The maximum gradient is one of 105ft. per mile between 23rd and 34th Streets. This has been surmounted with ease with fairly well loaded trains, and on several occasions an average speed of 20 miles an hour has been attained.

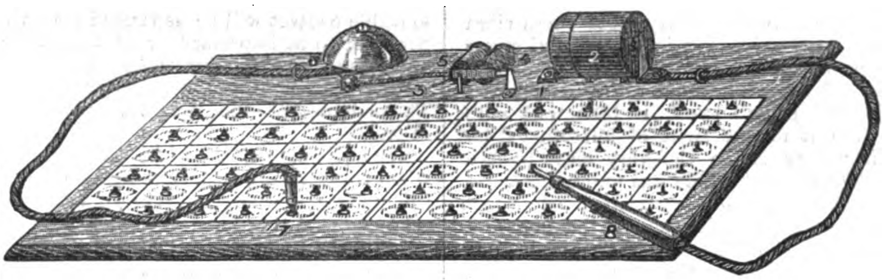
The track is vitalised by dynamos situated at the main station on 15th Street, about 200 yards from the track, it having been considered desirable to place the vitalising machines as near one end of the track as possible, so as to show the influence of distance in lowering the potential.

The effect of these two miles is, therefore, rendered equal to four miles where the station is centrally placed, and the loss of energy at the extreme end is barely observable. The vitalising system at the station consists of three No. 5 Daft dynamos, actuated by a Wright automatic cut-off steam engine, having a cylinder 18 × 42in., and a flywheel 16ft. by 26in. There is, in addition, a small arc-light Daft dynamo used for lighting the station and boiler room. The machines are connected with a switch-board, so that they can be placed in "parallel" or "series," as may be desired, and there is in addition an automatic cut-off, which operates in the event of a short circuit on the track, so as to open the circuit at a fixed point, and at the same time give the engineer notice by ringing an alarm. There is also an attachment to indicate when the short circuit is removed. The machines are connected to the track by means of 0000 copper wire, with Underwriter's line insulation suspended upon poles.

The motor has already run several hundred miles on the short track at 14th Street, making many hundred stops and starts, involving much severe work, hauling four cars for a considerable portion of the time, and also a two car train, for the purpose of making close observations as to the difference in consumption of fuel. With regard to this all-important question, the tests are as yet necessarily incomplete; but so far as they have gone, the indications are claimed to be eminently satisfactory. The extraordinary adhesive properties of a locomotive operated in this manner are evident. This feature is well illustrated on the line in Baltimore, which at one point has a curve of 75ft. radius on a gradient of 353ft., and yet no difficulty has been experienced by the motor in ascending this grade with a loaded train. So successful has been the working of the Baltimore road that two more motors have been ordered, making a total of four.—*Scientific American.*

A CHRISTMAS BOX.

The Electrical Apparatus Company has just introduced an electric toy which will be found very suitable for a Christmas



Box to children. Santa Claus is still expected to shower benefits on children at Christmas time.

The toy consists of electric bell circuits below a board. The circuits are left open and can be completed by the child. The contact pieces consist of a number of pins standing out of the board. In order to make the toy interesting a number of questions are printed on the left-hand half of a perforated cardboard, the answers being printed on the right-hand side. The cardboard is placed over the contact pieces, and a contact clip at the end of a flexible wire placed on the wire coming through the square in which the question is which requires an answer. A contact piece at the end of another flexible wire is brought consecutively into contact with the wires coming through the answer part of the card till the bell rings, when the child knows that the answer upon that square is the answer to the question asked. Full directions are issued with each "Automatic Instructor," which, so far as we have tested, acts admirably.

REIS'S ACOUSTICAL TELEPHONE. *(Concluded from page 54.)*

"Fig. 18 illustrates discord (*Dissonanz*). Why discords impress us unpleasantly I will leave my readers to judge at this time, though I may, perhaps, return to the subject subsequently in another paper.

"From the preceding it follows :—

"*First.*—Every tone and every combination of tones, on striking our ear, cause vibrations of the drum of the ear, the succession of which may be represented by a curve.

"*Second.*—The succession of these vibrations alone gives us a conception (*Sensation*) of the tone, and every alteration changes the conception (*Sensation*)."

The terms condensation and rarefaction as applied to sound-waves are entirely relative in their nature. A medium transmitting a sound-wave is rarefied when its density is decreased, and condensed when its density is increased beyond what it originally was, the extent or ratio of the condensations or rarefactions representing the amplitude of the sound-waves. Practically, then, the amplitude represents the amount of energy charged on the medium in order to mould it into waves. In the case of interfering waves, the amount and distribution of the energy in the resulting wave depends on the amount and distribution in the component waves. When the direction in which the energy acts is the same in, say, two waves, the amplitude of the resultant wave is the sum of the amplitudes of the two. If the direction is opposite, the amplitude of the resultant wave is the difference of the two. Two waves may completely obliterate each other, provided they simultaneously affect the same particles of the medium in opposite directions, with equal intensities, and for equal lengths of time; or, as it may be otherwise expressed, if the waves meet in opposite phases, are of equal amplitudes, and are of the same wave lengths.

Considering now the curve shown in the upper part of Fig. 17, as resulting from the simultaneous action of the notes *c*, *e'*, *g*, and

Digitized by Google

c', it will be noticed that the condensation rises while the four notes are simultaneously condensing the air, but begins to fall when part of them are endeavouring to rarefy it as is indicated ; for example, between the third and the sixth abscissa, where a gradual fall is shown, while between the sixth and seventh abscissa, and for some distance beyond, the fall is more sudden. Now, although in a general sense, it is correct to regard the curve between the first and the 7½th abscissa as indicating a condensation of the medium propagating the wave, yet it is equally correct to regard all that part of the curve between the third and 7½th abscissa as representing a rarefaction of the medium, superposed on the condensation, since a decrease of the condensation at any time is practically a rarefaction. Moreover, its effect is practically the same as that of a rarefaction, since if the condensation moves the medium in one direction the rarefaction moves it in the opposite direction.

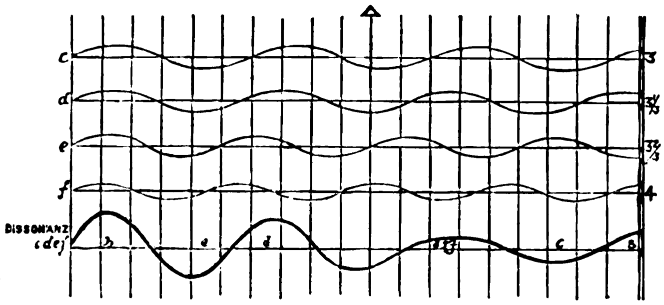


FIG. 18.

Studying Reis's curves in this light, is it not clear that he never could have intended to use the words "make" and "break" in the sense ascribed to him, but that when he spoke of the interruption occurring at every condensation and rarefaction he uses these terms in the sense above indicated? Does not the elastically-supported contact, with its adjusting screw, show that he did not intend the contact to leave the diaphragm completely, but that he wished it to follow its finer motions? Does he not say in the *Jahresbericht* article, "but the quality of the note depends upon the number of variations of amplitude (*Anschwellungen*) occurring in the same time?" "Now, my apparatus gives the number of the vibrations, but with far less strength than the original ones; though also, as I have cause to think, always proportional to one another up to a certain degree. But because the vibrations are throughout smaller, the difference between large and small vibrations is much more difficult to recognise than in the original waves, and the wave is therefore more or less indefinite."

If his apparatus, as he left it, with the elastically-supported contact and its adjustable spring, will speak in 1885, with absolutely nothing added to it, is it in the light of 1876 that it has been made to work? Is it not rather in the very clear light of 1860 and 1861, when the *Jahresbericht* article was published?

There are two other points in the *Jahresbericht* article which throw some light on the meaning which should be given to Reis's use of the words "make" and "break." The first of these is to be found in his description of the action of the core of the magnetising spiral. "The intensity also of this tone is proportional to that of the original one; for, in proportion as this is more intense, the motions of the membrane are greater, the motions of the hammer, also, and finally the time during which the circuit remains opened is greater, and, consequently, up to a certain limit, the motions of the atoms in the reproducing wire are greater, we perceiving them as greater vibrations in just the same way as we would have perceived the original sound-wave." If the "opening" of the circuit here referred to means, as we have suggested, its gradual increase in resistance, while the diaphragm was under the influence of the rarefaction, or while it was moving in a certain direction, then we can understand how the instrument could reproduce variations in the intensity of the transmitted sounds ; but, if it mean a complete break, then, since it is difficult to understand how the circuit, if completely broken, can be anything more than broken, it is equally difficult to see how the duration of the complete break could effect the intensity.

Again, Reis's claims as to the capabilities of his instruments "now in reference to the capabilities of the telephone," . . . "experiments showed that the sounding wire was capable of reproducing complete chords of three tones of the piano;" that is to say, it was capable of transmitting quality which would be clearly impossible if the instrument acted on the "make" and "break" principle in the sense claimed by the advocates of Bell.

If the paragraphs in Reis's article, in which he refers to the "making" and "breaking" of the circuit stood by themselves, then it might be admissible to put the construction on them before referred to; but, taken in connection with the other declarations and explanations of Reis, we do not see that such interpretation stands at all.

If, however, such interpretation be sustained, then it simply amounts to this—viz., that Reis did not understand the theoretical operation of his instrument. But we fail to see how this can injure his position as an inventor. If he produced an instrument whose mechanical structure was such as would permit it to reproduce articulate speech, and properly instructed others how to make and use it, then he is the true inventor of the same, no matter how erroneous his ideas may have been as to its theoretical operation. If, as is undoubtedly the case, scientific opinion of the present day is still uncertain as to what is the exact theory of the action of the articulating telephone, then Reis may justly be excused if he erred in his description of the same. Should Bell's theory of the undulatory character of the transmitted current, in the sense in which he claims it, be fallacious, as is by no means improbable, then are his claims to the modified forms of apparatus that he has produced to be regarded as untenable?

In the Legat description of Reis's apparatus already referred to we note the following in speaking of the movable contact :— "It is advisable to make the arm *c*, *e*, longer than the arm *e*, *d*, in order that the least motion at *c*, may operate with the greatest effect. It is also desirable that the lever itself may be made as light as possible, *that it may follow the movements of the diaphragm* (our italics). Any inaccuracy in the operation of the lever *c*, *d*, in this respect will produce false tones at the receiving station." The necessity for the contact to follow the motions of the diaphragm is precisely what we have insisted on. Legat, for some reason or other, does not appear to have obtained any valuable results with the instruments with which he experimented.

It would appear to be an assumption, bordering on impertinence, to deny to the man whose genius created the most marvellous instrument of modern science, a knowledge of the simplest principles underlying the operation of the instrument he has constructed. It is incredible that he, who modelled his transmitting instrument after the human ear, who explained so thoroughly by curves the peculiarities of the motion of its tympanum, and who wrote, "the function of the organs of hearing, therefore, is to impart faithfully to the auditory nerve every condensation and rarefaction occuring in the surrounding medium ; the function of the auditory nerve is to bring to our consciousness the vibrations of matter resulting at the given time, both according to their number and magnitude," could have so blundered, as to desire to obtain results that he especially designed the mechanical structure of his apparatus to avoid.

Any form of variable contact transmitter will cease to properly operate if spoken to in too loud a tone, since in such a case the movable contact will be separated from the diaphragm too long to permit it to be impressed by all its motions. By the use, however, of the regulating screw the pressure of the elastically-supported contact may be varied, so as to permit a fair use with a loud tone. This is true with the Reis transmitters, and equally true of the others.

We again assert, therefore, that the Reis transmitters operate, when transmitting articulate speech, in precisely the same way as the modern receivers, and presumably in the very way that Reis intended that they should operate, but that, however this may be, even admitting that he so strangely erred in his explanation of the way in which he conceived it to operate, then, nevertheless, if his description of the mechanical structure of his apparatus, and of the manner in which it was intended to be used, is such as to enable a skilled mechanic, with no other knowledge of the art than that imparted to him by Reis's publications and drawings, to make and use the same, then Reis is the first true and only inventor, and to him must be awarded priority of invention over all others.

Since the object of the contact pieces is to vary the electrical resistance of the circuit in which they are placed, by altering the extent of surfaces in contact, they must, of course, have been formed of some electrical conducting substance. Since, if such substance were liable to oxidation, it might, apart from the motions of the diaphragm, thus introduce a varying resistance into the circuit, the substance must not be readily oxidised. Reis employed for his contact pieces metallic platinum. Berliner, Blake, and, indeed, nearly all later inventors have replaced the platinum by hard carbon, since Hughes pointed out its superiority. This material, though perhaps better in degree, does not differ in the manner of its operation, as is indeed shown by the fact that the Berliner or the Blake transmitters will operate satisfactorily when their carbon contacts are replaced by metallic platinum, or that, conversely, the Reis transmitter will operate if furnished with carbon contacts.

In the early history of the Reis-Bell controversy, it was denied by the advocates of Bell that it was possible to make the Reis apparatus talk. When, however, it was proved by the most unquestioned testimony, and by actual demonstrations, that the Reis apparatus could and would talk, instead of fairly according to him the merit of the discovery, they adopted the specious plea that even if the apparatus would talk, it was only in the light of the experience of Bell that it could be made to do so ; that is, that the success of actual use of the Reis apparatus was by the use of the

Digitized by Google

knowledge gained since 1876. Such reasoning would appear too illogical to need refutation. Let us, however, present the same reasoning in another light.

An apparatus, designed by Reis, to transmit articulate speech, made, we will say, in 1861, is left unnoticed in that strange way in which the world has too often failed to accept the gifts of genius, if born out of time. It slumbers amid the dust of age and neglect, while its inventor, unable to convince the world of its great value, at last dies disappointed and heart broken. Temporarily forgotten, it is re-invented by another and accepted by the world as the greatest discovery of modern time, and no honours are deemed too great for its supposed inventor. Again brought to light, the original apparatus is compared with the later alleged invention and found to resemble it in a remarkable manner. Doing absolutely nothing but to remove the accumulated dust of many years, it is placed in circuit with another receiver, or, indeed, even with its own receiver, and lo! it talks. Surprised at this success, the experimenter searches for Reis's description of such apparatus, and finds that he and others claim to have talked through such apparatus long ago. What, then, should be his indignant surprise, as one possessing that true scientific instinct of desiring to know the truth for the truth's sake, to be told that Reis must have falsified his record when he stated that such an apparatus would talk; that had it not been for Bell, the Reis apparatus would never have spoken? If it be a telephone in 1885, why was it not equally a telephone in 1861, especially when it was designed to talk, and when, if the most solemn statements are to be believed, it did talk? It is not, perhaps, saying too much to add that a defence of such a character is open to grave suspicions of insincerity.

And yet, what is the position in which the advocates of Bell insist on placing him, in order to enable them to continue to maintain his patent rights in the United States? Do they not assume for him a declaration that might not unfairly be worded as follows:—"I have made a grand and great discovery of so novel a character that I demand, for its protection, the broadest and most general patent that can be issued. I have discovered that if I use the regulating screw placed by Reis in an apparatus improperly called by him a telephone, and obtain a certain pressure of an elastically-supported contact against a diaphragm, that the apparatus will do what Reis and others claim that it did many years ago, but which I do not believe they ever accomplished. My discovery, therefore, is of so novel a character that I claim in general the use of electricity in the transmission of articulate speech, and consider it a sufficient proof of the infringement of my patent rights if any one hereafter succeeds in actually transmitting speech electrically."

Is Mr. Bell willing to permit others to continue to make such claims for him? We can hardly believe that his known sense of fairness will permit him to continue to do so. The credit that is legitimately due him, and which all are willing to acknowledge, should suffice, without his permitting others to endeavour to appropriate for him that due to Reis.

It has been said, "a century of Reis would not produce a speaking telephone," because Reis did not give the correct explanation of the manner of operation of his instrument. We beg leave to differ entirely from this statement. The apparatus of Reis, so far as its mechanical structure and the way in which it was designed to be used are concrrned, are entirely independent of any theoretical explanations of how such apparatus operated to produce the results for which they were designed. According to such reasoning, a century of Franklin would never produce a lightning rod, since Franklin, although he gave a full and correct description of the construction of his lightning rod, and explained how it was to be placed on the building it was designed to protect, alleged that the manner in which it operated was by drawing a hypothetical electrical fluid from the surcharged cloud and quietly conveying it to the ground. At the present, we do not believe in the fluid theory of electricity; therefore, there never was a lightning rod, and no such instrument can act as a lightning rod until we know the exact manner in which it lowers the higher potential of the cloud to that of the earth. Is not such reasoning nonsensical, and could it not be enlarged indefinitely?

It is an interesting fact that Bell approached the invention of his form of articulating telephone from very nearly the same standpoint as Reis; that is, from a study of the curves resulting from the combination of different tones, with, however, this difference. Reis designed his curves to represent the variations in the amplitude of the sound-waves, or the variations in the movements of the diaphragm of the receiving instrument. Bell, on the contrary, employed his curves to represent electrical undulations. Quoting from the specification of his U. S. Patent, No. 174,465, of March 7, 1876:—

"Electrical undulations, induced by the vibration of a body capable of inductive action, can be represented graphically, without error, by the same sinusoidal curve which expresses the vibration of the inducing body itself, and the effect of its vibration upon the air; for, as above stated, the rate of oscillation in the electrical current corresponds to the rate of vibration of the inducing body; that is, to the pitch of the sound produced. The intensity of the current varies with the amplitude of the vibration—that is, with the loudness of the sound; and the polarity of the current corresponds to the direction of the vibrating body—that is, to the condensations and rarefactions of air produced by the vibration. Hence, the sinusoidal curve, A or B, Fig. 4 (our Fig. 18), represents, graphically, the electrical undulation, induced in a circuit by the vibration of a body capable of inductive action."

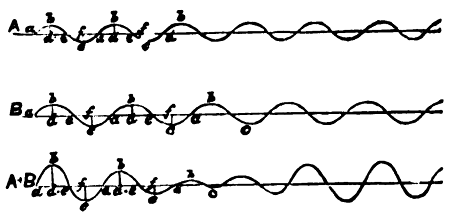

Fig. 18.—Curves Representing Electrical Undulations from Fig. 4, of Bell's U. S. Patent, No. 174,465.

The horizontal line, *a*, *d*, *e*, *f*, &c., represents the zero of current. The elevation, *b*, *b*, *b*, &c., indicates impulses of positive electricity. The depression, *c*, *c*, *c*, &c., show impulses of negative electricity. The vertical distance, *b d*, or *c f*, of any portion of the curve from the zero line expresses the intensity of the positive or negative impulse at the part observed, and the horizontal distance *a a* indicates the duration of the electrical oscillation. The vibrations represented by the sinusoidal curves B and A, Fig. 4, are in the ratio aforesaid of 4 to 5—that is, four oscillations of B, are made in the same time as five oscillations of A.

"The combined effect of A and B, when inducted simultaneously on the same circuit, is expressed by the curves A+B, Fig. 4, which is the algebraical sum of the sinusoidal curves of A and B. This curve, A+B, also indicates the actual motion of the air when the musical notes considered are sounded simultaneously. Thus, where electrical undulations of different rates are simultaneously induced in the same circuit, an effect is produced analogous to that occasioned in the air by the vibration of the inducing bodies."

The difference between Reis and Bell, then, is as follows:—Reis insisted on the necessity of reproducing in the diaphragm of the receiving instrument similar movements to those in the transmitting diaphragm, and endeavoured to obtain this result by an elastically-supported regulable spring, through the action of what he called makes and breaks. Bell also insisted on the reproduction in the receiving diaphragm of the motion of the transmitting diaphragm, but declared that in order to achieve this result exactly similar undulations must be given to the electrical current that traverses the wire between the two stations. Reis, it will be observed, designed his curves to represent electrically the magnetisation of the receiving electro-magnet, which, as Legat describes, "will be magnetised, and demagnetised correspondingly with the condensation and rarefaction of the mass of air," "and the armature belonging to the magnet will be set into vibrations similar to those of the membrane in the transmitting apparatus." Both inventors insisted on the necessity for an undulatory effect. Bell places it in the current as it leaves the transmitter; Reis in the magnetic field of the receiving magnet. Let us see, therefore, which explanation is the more nearly in accord with the facts as they are now generally accepted.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

At the meeting of this Society on Thursday, Nov. 26, Mr. Spagnoletti in the chair, Dr. J. A. Fleming, M.A., read a paper "On the Necessity for a National Standardizing Laboratory for Electrical Instruments." Dr. Fleming began by quoting a passage from the writings of Sir John Herschel with which everybody at this day must agree, namely, that, although formerly in the pursuit of individual research arbitrary standards of measurement were permissible, directly reasearch becomes general there arises the necessity for uniform standards accepted and employed by all. The early pioneers of electrical science, like Cavendish, had to devise standards of their own, which, however, had no universal adaptability. In recent years the theoretical standard had been settled, or, more correctly, an approximate agreement had been arrived at. But its identity in practice was far from complete, and the object of his paper was to suggest a central and recognised institution where the standards commonly in use could be tested, and absolute identity be insured. This had become a matter as much for the public convenience and welfare as the Yard Measure at Greenwich or the Thermometer test at Kew. Electrical industry had

Digitized by Google

immensely increased during the last few years, especially in the field of electric lighting; yet, except at the Cavendish Laboratory, Cambridge, no sort of electrical certification corresponding to the "hall mark" on gold and silver could be obtained anywhere. Great pains, no doubt, are taken by the makers of electrical standards of measurement; but independent views still prevail as to the ampere and the volt that would not be tolerated in the case of eighteen carat gold; and owing also to the unavoidable differences arising out of different makes of instruments a great deal remains to be done before electrical measurement is brought to a condition of certainty like time and mass. No very useful result had followed the labours of the Paris Electrical Congress in this direction, the French standard and the English still maintaining their divergency. After quoting the late Prof. Fleeming Jenkin's opinion with regard to the worthlessness of uncertified copies of measures which themselves are not certified, Dr. Fleming went on to consider his proposition, first, in relation to the requirements of pure science, and then to those of electrical engineering. Unless there is absolute identity of measurement among different observers the published results of their experiments will be misleading; and in the manufacture of electrical appliances the practical inconvenience of varying standards is every day felt to be more and more serious. Everybody must admit that the highest possible uniformity is desirable; the only question was, how is it to be obtained? The establishment of a national standardizing institution would meet this want. Put in relation with such places as Greenwich and Kew, and possessing both the means of independent research and the assistance of experienced persons, such an institution would not only design the best standard instruments, but would be an authority to which all makers would resort to have their work certified. Dr. Fleming described in some detail what such an establishment should be, pointing as an illustration to Lord Rayleigh's laboratory and his methods of work. A moderate fee should be charged, and would not be grudged for certified tests conducted under such high authority. It would then be the vendor's or buyer's own fault if absolute exactness and uniformity did not soon everywhere prevail in this country. Other countries would soon follow our example. Besides this an institute of the kind he contemplated might be used for the testing of electrical materials, which varied with commercial morality as well as commercial ignorance. It would give the direction and impetus to experimental research; and would probably furnish experimental proof of many important theories which are still wanting verification. Quantitative research would not pay as a commercial undertaking, although the case of the French Academy of Science was not altogether discouaging.. This brought him to the question of funds. Many people objected to the endowment of research as generally tending to the research of endowments [laughter]; but our choice lay between private munificence and a public benefaction. There was a public fund which he thought might be appropriately applied to the object he had in view, namely the fees of the Patent Office. Through the recent Patent Act a vast increase had taken place in the number of patents taken out. In 1883 there were about 5,000 only; but in 1884 they had risen to 17,000, of which about 1,400 related to electrical inventions. The revenue from this source was very considerable; and he thought that efforts should be made by such a society as that of the Telegraph-Engineers and Electricians, backed by the Royal Society and British Association, to secure some of this money for the public endowment of an institution, the importance of which to electrical progress was growing more urgent every day. The net outcome of his paper might, in conclusion, be summed up as follows:—First, that unity of operation in this branch of science was desirable; secondly, that the standards recognised as authoritative should be lodged in some one place; thirdly, that this place would preferably be a national standardizing institution; fourthly, that the proper body to initiate the scheme would be the Society of Telegraph-Engineers; and, lastly, that the council be invited to take the matter up with the Royal Society.

Mr. CHANEY, of the Board of Trade, thought that what was needed most was, not new units or new standards, but uniformity of the measures used in the trade, especially for that of electric lighting. He gravely doubted the expediency of mixing up research with a question of this sort, and feared that the one proposal might embarrass the other. The expense of an establishment for standardizing would not be very great, and he saw no insurmountable difficulty in the way of creating and maintaining it. He was sure that the Board of Trade would listen very attentively to a proposition of that kind, and if a legal force were thought necessary to the validity of the certification, it could probably be obtained through an Order in Council.

Mr. WHIPPLE, of the Kew Observatory, agreed with Mr. Chaney in regard to the separation of the two schemes, and pointed to the adaptability of Kew for the particular object aimed at. Funds for similar tests of thermometers, watches, &c., which are certified there have been obtained by grants from the Royal Society.

Mr. JACKSON, of the Patent Office, furnished some particulars as to the number and value of electrical patent fees, which appeared to have been rather over-estimated.

Captain CARDEW thought, for his part, that what was most needed was permanency in the standards; they might be trustworthy to begin with, but the difficulty was to keep them so.

Captain SANKEY and Mr. CROMPTON spoke as to the pressing importance of some recognised standardizing, as did also Mr. PREECE, who stated that the "legal" ohm adopted at Paris having proved to be wrong, like the old standard ohm, had been abandoned by the Postal Telegraphs in this country, and their example would, he believed, be followed in the United States and by Germany.

Profs. FOSTER and ADAMS having also spoken, a resolution, proposed by Mr. C. H. W. BIGGS, calling upon the Society to take the initiative in this matter, was carried unanimously; and after the usual vote of thanks the meeting separated.

The following is the list of Council and Officers proposed to be balloted for at the next meeting of this Society. It will be seen that the Council has adopted the plan of submitting a list to the members, from which they may select their representatives:—

PRESIDENT.

Prof. D. E. Hughes, F.R.S.

VICE-PRESIDENTS.

(Four to be elected.)

Sir Charles Bright, M. Inst. C.E.
Edward Graves.
Colonel Sir Francis Bolton.
J. Hopkinson, M.A., D.Sc., F.R.S.

ORDINARY MEMBERS OF COUNCIL.

(Twelve to be elected.)

William T. Ansell, F.R.G.S.
Prof. W. E. Ayrton, F.R.S.
E. B. Bright, M. Inst. C.E.
R. E. Crompton, M. Inst. C.E.
William Crookes, F.R.S.
Prof. George Forbes, M.A., F.R.S.E.
Alexander Siemens.
Augustus Stroh.
} *Remaining on Council.*

Recommended by Council, and *four* of whom may be selected by running the other four names through with the pen:—

Captain Charles F. C. Beresford, R.E.
Shelford Bidwell, M.A., LL.B.
Captain Phillip Cardew, R.E.
Conrad W. Cooke.
J. A. Fleming, M.A., D.Sc.
Prof. John Perry, F.R.S.
W. H. Stone, M.A., F.R.C.P.
Prof. Silvanus P. Thompson, B.A., D.Sc., F.R.A.S.

ASSOCIATE MEMBERS OF COUNCIL.

Recommended by Council, and *three* of whom may be selected by running the other three names through with the pen:—

(Three to be elected.)

Colin Brodie.
W. Lant Carpenter, B.A., B.Sc.
Gisbert Kapp.
William M. Mordey.
John Munro.
P. W. Willans.

HONORARY TREASURER.

Edward Graves.

HONORARY SECRETARY.

Colonel Sir Francis Bolton.

LIGHTHOUSE ILLUMINANTS.—ELECTRIC LIGHT APPARATUS.

REPORT OF PROF. W. GRYLLS ADAMS, F.R.S., &c.

(Continued from page 60.)

Experiments in the Photometric Gallery.

On September 24th an attempt was made to compare the electric light from large 40 mm. solid carbons with the light from the pentane gas holder, altering the height of the pentane flame so as to balance the light from the electric arc according to Mr. Harcourt's scale for the pentane flame.

The photometric disc was at a distance of 138 ft. from the arc.

The mean of several observations gave the following results:—With an E.M.F. of 45·8 volts and a current of 165·7 amperes (giving 7,593 mean watts) there was a mean illuminating power of 15,300 candles, the machine employed to give the current being the L No. 1 machine. Great difficulty was found in measuring the light in consequence of the difference of colour between it and the standard.

On the evening of September 24th the current from one machine to the "A" tower was 100 amperes, and the electromotive force at the terminals of the machine was 60 volts and at the extremities of the arc on

Digitized by Google

the lower stage was 45 volts, and at the extremities of the arc on the upper stage was 38 volts; thus, with the wires to the lower stage in the "A" tower there was a difference or loss of 15 volts, and with those to the upper stage a difference of 22 volts, wasted on the leads; showing that in the first case, *i.e.*, with the thick leads to the "A" tower the loss was one-fourth of the whole, and with the smaller leads to the "A" tower the loss was $\frac{1}{16}$, or more than one-third of the whole, in consequence of the high resistance of the leads.

On October 17th experiments were made in the photometric gallery. The electromotive force was measured at the extremities of the arc. The current was measured in the photometric gallery by a Siemens electro-dynamometer. During the evening Mr. V. Harcourt was engaged in measuring the intensity of the light by means of his pentane standard flame and the star disc photometer.

The electromotive force and current continued quite steady throughout the evening, giving a mean electromotive force of 35 volts at the extremities of the arc, and a current of 160 amperes, giving 5,550 as the mean watts.

The machines are now shown to be pretty nearly equal in their yield of electrical energy, and to work in an exceedingly satisfactory manner.

When two machines were supplying current to one arc, or even with a single machine, the carbons and the whole lamp became very hot, and had to be very frequently changed. To obviate this, at Dr. Hopkinson's suggestion, a shunt or by-pass was arranged to the lamp so as to carry a large percentage of the current direct to the lower carbon, only allowing a portion of it to go through the lamp sufficient to regulate the carbons, and keep them at their proper distance apart. This shunt is a great improvement, for with it the same lamp may be used without injury throughout a whole evening's experiments.

On October 18 two machines, L No. 1 and L No. 2, were worked together, *without being clutched*, to supply current to an arc in the photometric gallery. At Dr. Hopkinson's suggestion a shunt to the lamp had been arranged, so as to carry more current to the 40 mm. carbons without over-heating the lamp. This arrangement proved very satisfactory, and the current through the arc was much greater than had been possible before, and yet the lamp did not become unduly heated.

The average electromotive force at the terminals of the machines was 46 volts, and the electromotive force at the extremities of the arc was 36 volts, the current through the arc being 278 amperes, giving 10,022 as the watts or energy absorbed per second in the arc.

This is equivalent to 13·4 horse-power.

These experiments were repeated, and some other interesting experiments made, on October 18, when Dr. J. Hopkinson went with me to the South Foreland.

Two machines were started together, but independently, each being driven by its own belt, and they increased their speed in harmony, always going together until they reached their normal speed, when the electromotive force rose to 80 volts. The belt was now thrown off one of the machines, when the electromotive force at the terminals of the driving machine remained at 80 volts. A strap was placed round the pulley of the motor machine, and a weight of 14lb. was hung on the strap; the machines continued to run together, but the electromotive force oscillated from 80 to 78 volts as the weight rose and fell with the pull on the strap, being not heavy enough to give a steady pull. Thus one machine was being driven as a motor by another equal machine, and was doing work which was measured by the friction brake. The pulley was 16 inches in diameter, and the speed 600 revolutions, giving 35,200 foot-pounds per minute, or more than 1 horse power.

On putting on 28lb. on the pulley of the motor, the electromotive force was reduced from 80 volts to 78 volts, and remained steady, and the machines still ran together. On putting 42lb. on the brake on the pulley of the motor, the electromotive force was reduced to 76 volts, and then 56lb. was put on, when the motor continued to run at the same rate as the generator, and the electromotive force was steady at 74 volts.

On account of the heating of the extemporised brake strap, it was not thought advisable to continue the experiments by adding heavier weights, although there seemed to be every probability that the machines would continue to run together at the same speed, the one as generator and the other as motor and doing work. The above experiments show that the work done on the brake was 140,000 foot-pounds per minute, or more than 4 horse-power.

In another experiment the three machines were started together, and run up to their usual speed of 600 revolutions per minute, each machine being driven by its own belt. The belts were then thrown off two of the machines, and they were driven as motors by the current from the third machine, the electromotive force at the terminals of the third machine being the same as when the three were running together in parallel circuit.

On November 10th I again made further experiments with the three De Meritens magneto machines, and made measurements of the light given by the arc worked from the machines separately and combined in parallel circuit.

The resistance of the leads from the engine room to the photometric gallery in which the measurements were made was ·032 ohm (cold), and the leads were heated considerably, and where exposed became quite warm to the touch when carrying the current from two machines or from the three machines.

One machine alone gave a current of 175 amperes, with an electromotive force of 40 volts at the machine terminals, and an electromotive force of 33 volts at the extremities of the arc, giving 5,775 watts expended in the arc and 1,225 watts expended on the leads.

Two machines worked well together, being driven independently, and gave an average current of about 275 amperes, with an electromotive force of 47·5 volts at the machine terminals, and an electromotive force of 35·5 volts at the extremities of the arc, giving 9,750 watts expended in the arc and 3,300 watts expended on the leads.

Another experiment with two machines gave an average current of 278 amperes, with an electromotive force of 48 volts at the machine terminals, and an electromotive force of 36 volts at the extremities of the arc, giving 10,000 watts as the energy per second expended in the arc.

These experements give for

(1.) One machine—
7,000 watts (electrical energy in external circuit);
1,715 watts (electrical energy in internal circuit);
giving 8,715 watts as the total electrical energy per second.

The power absorbed, as shown by indicator diagrams, during this running, was 13·8 horse-power, or 10,295 watts, giving an electrical efficiency of 84 per cent.

(2.) Two machines—
13,300 watts in the external circuit;
1,800 watts in the internal heating of coils;
giving 15,130 watts as the total electrical energy per second.

The power absorbed was 28·53 horse-power, or 21,280 watts, giving an electrical efficiency of 71 per cent.

The electromotive force and current remained as steady as when the two machines had been mechanically connected together by clutches, completely proving that with equal machines such mechanical connections are entirely unnecessary.

This we had also found to be the case in the experiments of October 18th, when experimenting with two machines, and also with the three machines running on the same parallel circuit. The third machine has no mechanical connection with the other two machines, except through the belting, being driven from the same countershaft. When run together, the three machines gave a steady current of 300 amperes through an arc with an electromotive force of 49 volts at the machine terminals, and of 37 volts at the extremities of the arc, giving 11,100 watts expended in the arc.

On account of the high resistance and consequent heating of parts of the lamp, and the irregularity of burning of the 40 millimetre carbons employed, the current from the three machines was only about 25 to 30 amperes greater than the current from the two machines.

In the experiments on November 10th, with the three machines driven independently in parallel circuit, there was considerable variation in the mean electromotive force and in the mean current. The irregularity was due to the very unequal burning of the carbons, which was noticed at the time of the experiments, and not to any irregularity in the working of the three machines; for as the electromotive force increased the current diminished, and there was comparatively little variation in the rate of work done in the arc. In one set of experiments the electromotive force varied from 42 to 32 volts, and the current from 270 to 310 amperes, yet the product remained much more nearly constant, and the average was about 11,000 watts. In another set the electromotive force varied from 41 to 37 volts, and the current from 290 to 316 amperes, giving an average of 11,600 watts in the arc.

The belt was now thrown off the third machine, which still continued at the same uniform speed, being driven as a motor by the current from the other two machines, with the arc still in the external circuit. Thus, of three alternate-current machines arranged in parallel circuit to supply current to an external circuit, one may be run as a motor by the current from the other two, which will continue to supply an arc in the external circuit. The electromotive force at the extremities of the arc and the current through the arc were measured, and experienced wider variations than in the last experiment with three machines parallel, but the power in the arc remained very constant at about 12,000 watts, rather greater than when the three machines were driven directly from the engine. The arc also was observed to be steadier when the third machine was being driven as a motor, as though the motor acted as a governor on the circuit. The electromotive force at the extremities of the arc varied from 52 to 41 volts, with occasional readings outside these limits, and the current varied from 240 to 285 amperes, the electromotive force rising when the current diminished in such a way that the product remained very nearly constant. It would seem from these experiments that the work done in the arc with two machines combined in parallel circuit, without the third machine in the circuit at all, was considerably less than the work done when the two machines were supplying the arc, and at the same time driving the third machine as a motor.

Not only so, but when the machines were all three driven directly from the engine, the work done in the arc was rather less than the work done when the two machines were supplying the arc, and at the same time driving the third machine as a motor. These remarkable results are also borne out by the photometric results obtained during these experiments.

With the kind assistance of Mr. Longford and two of my students, Messrs. Anderson and Wordingham, I was able to measure the current, the electromotive force at the terminals of the machine and at the terminals of the arc, as well as the candle-power throughout the experiments. The photometer employed was Dr. Hopkinson's dispersion photometer, in combination with a star disc and a paraffin lamp with a Methven slit. Ruby glass and ammonia sulphate of copper solution placed before the eye were employed to compare the intensities of red and blue in the two sources of light. By the Hopkinson photometer an illuminating power of 16,000 candles was reduced to six candles within a distance of 100 inches from the arc. The illuminating power given by the arc fed by the current from one machine was measured at a distance of 50 inches from the arc, and was found to be, with red light, 8,000 times, and with blue light, 16,000 times the light of the standard light.

At the same distance, the current from two machines gave 15,000 times the standard, as measured by red light. For these and higher candle-powers it was found convenient to remove the dispersion photometer to a distance of 100 inches from the arc.

The illuminating powers given by the current from two machines were then found to be 13,500 by red light, and 23,200 by blue light.

Digitized by Google

The illuminating powers of the current from three machines driven in parallel circuit were 16,000 by red light, and 31,000 by blue light; and when the two machines fed the arc and drove the third machine as a motor, the illuminating power was 17,300 as measured by red light.

TABULAR STATEMENT OF RESULTS.

—	E.M.F. at the arc.	Current.	Watts in the arc.	Illumination.	
				By red light.	By blue light.
With one machine ...	33	175	5,775	8,000	16,000
With two machines...	35·5	275	9,750	13,500	23,200
	36	278	10,000		
With three machines	37	300	11,100	16,000	31,000
	42 to 32	300	11,000		
	41 to 37	310	11,600		
With two machines driving the third as a motor...............	52 to 41	240 to 285	12,000	17,300	

With the large current of 300 amperes, the difference of electromotive force due to the resistance of the *leads to the photometric gallery* is 12 volts, or one quarter of the whole, and the total power of 14,700 watts is diminished by 3,600 watts from this cause.

October 18th. The 40 mm. carbons employed very soon became red-hot throughout their whole length, when three machines were employed giving a current of 300 amperes, so that it was impossible to continue the experiments long.

The diameter of the crater formed in the carbons was 22 millimetres. The light varied from 14,700 candles to 24,000 candles with two machines to one arc.

The light varied from 16,400 candles to 29,600 candles with three machines supplying the current to a single arc.

During the evening of October 18th, measurements were made by Sir J. Douglass in No. 2 hut.

The single electric light was exhibited in the "A" tower, being supplied from machine L No. 3.

The electromotive force was measured at the same time in the engine room at the machine terminals, and also in the "A" tower at the extremities of the arc. The current was about 100 amperes.

The electromotive force at the machine terminals was 45·5 volts.

The electromotive force at the extremities of the arc was 30·5 volts, showing that only about two-thirds of the available external energy was expended in the arc, one-third of the energy being wasted in the leads from the L No. 3 machine to the "A" tower. This confirms the result observed on September 24th.

On October 25th, as the photometric gallery was occupied by Mr. Harcourt, I was engaged in making measurements to determine the coefficient of self-induction of the three machines.

Taking γ as the coefficient of self-induction and T the periodic time, the value of $\frac{2\pi\gamma}{T}$ for the several machines was determined.

	$\frac{2\pi\gamma}{T}$		Internal Resistance.
For L No. 1 machine	·305 ohm	=	·044
For L No. 2 machine	·2967 ohm	=	·049
For L No. 3 machine	·323 ohm	=	·056

With these high coefficients of self-induction the machines run very steadily and are less affected by variations in the arc, and, with their small internal resistances, are exceedingly well adapted for lighthouse work, where the arc would usually be not far away from the machine; but where used with long leads of considerable resistance, as at the South Foreland experiments, the loss of energy is great in consequence of the small internal resistance of the machines.

November 8th. In the previous determinations of the intensity of the electric light, the light was compared with standards of one or of about three candles, at distances from the arc varying from 140 to 350 feet from the arc.

On November 8th I made some experiments with Hopkinson's dispersion photometer, consisting of a small convex lens of 1·933 inch focal length, fixed in a tube fitted with diaphragms so arranged that a small beam from the arc entering the tube fell upon the lens. This lens brought the light to a focus, which became the source of light for the illumination of the Bunsen disc, and which was compared with the Douglass standard lamp.

The slit was arranged so as to give an illumination of one candle at a distance of one foot. When the lens was placed at a distance of 8 feet 6 inches, or 102 inches from the arc, the dispersive power of the photometer reduced an illuminating power of 16,000 candles to a focus giving an illuminating power of about six candles.

The power of the lens being

$$\left(\frac{f}{u-f}\right)^2 = \left(\frac{1\cdot933}{100}\right)^2 = \cdot0003738, \text{ or } \frac{1}{2,675},$$

or the multiplying factor being 2,675.

(To be continued.)

BRITISH ASSOCIATION.

Report of the Committee, consisting of Prof. G. FORBES, Captain ABNEY, Dr. J. HOPKINSON, Prof. W. G. ADAMS, Prof. G. C. FOSTER, Lord RAYLEIGH, Mr. PREECE, Prof. SCHUSTER, Prof. DEWAR, Mr. A. VERNON HARCOURT, and Prof. AYRTON, appointed for the purpose of reporting on Standards of White Light. Drawn up by Prof. FORBES.

The experimental work of the Committee during the past year has not been extensive, as they had no funds at their disposal for experimental research, and they have been chiefly occupied with reviewing what has been done in the past and laying plans for future operations.

Lord Rayleigh has constructed an instrument which he calls a monochromatic telescope, by means of which the illuminated screens of a photometer may be examined, allowing light only of one definite colour to pass. It was hoped by Lord Rayleigh that experiment might show that, with some suitably chosen colour, this instrument, used with any ordinary photometer, would, in comparing lights of different intensities and temperatures, give to each a candle-power which would be sufficiently accurate to represent for commercial purposes the intensity of the light. The secretary has made some experiments at the Society of Arts, where he was kindly permitted to use the secondary batteries and glow lamps; but the results so far are not definite enough to justify their publication.

Mr. Vernon Harcourt has been engaged on an investigation on the barometrical correction to his pentane standard, and on another concerning the possibility of using lamp shades as a protection from air currents. His researches are communicated independently to the meeting.

Captain Abney and Colonel Festing have continued their observations on the intensity of radiations of different wave-lengths from incandescent carbon and platinum filaments at different temperatures.

Other isolated experiments have been made by members of the committee, which will be published in due course.

Most of the members have examined the experiments of the Trinity Board at the South Foreland.

Existing Standards.

A consideration of existing standards convinces the Committee that the standard candle, as defined by Act of Parliament, is not in any sense of the word a standard. The French "bec Carcel" is also liable to variations; and with regard to the molten platinum standard of Violle, it seems that the difficulty of applying it is so great as to render its general adoption almost impossible.

With regard to the so-called standard candle, the spermaceti employed is not a definite chemical substance, and is mixed with other materials, and the constitution of the wick is not sufficiently well defined. Hence it is notorious that interested parties may prepare candles conforming to the definitions of the Act which shall favour either the producer or consumer to a serious extent. In view of these defects of the standard candle, it is a matter of great importance that a standard of light should be chosen which is more certain in its indications.

The Committee have looked into the merits of different proposed standards, and the majority feel satisfied that, for all the present commercial requirements, the pentane standard of Mr. Vernon Harcourt—since it has no wick and consumes a material of definite chemical composition—when properly defined, is an accurate and convenient standard, and gives more accurately than the so-called standard candle an illumination equal to that which was intended when the Act was framed.

Yet the Committee, while desiring to impress the Board of Trade and the public with these views, do not feel inclined at present to recommend the adoption of any standard for universal adoption until, further information on radiation having been obtained from experiment, they may learn whether or not it may be possible to propose an absolute standard, founded, like electrical and other standards, on fundamental units of measurement—a standard which, for these reasons, would be acceptable to all civilised nations. They are, however, inclined to look upon the pentane lamp as an accurate means of obtaining an illumination to replace the so-called standard candle.

Proposed Experimental Researches.

Radiation is measured as a rate of doing work, and consequently radiation might be measured in watts. The illumination (or luminous effect of radiation) depends partly upon the eye, and is a certain function of the total radiation. This function depends upon the wave-length of the radiation, or on the different wave-lengths of which the radiation, if it be compound, is composed. This function of the radiation perceived by the eye is partly subjective, and varies with radiations of different wave-lengths and with different eyes. Thus the illumination cannot, like the radiation, be expressed directly in absolute measurement. But the connection between the illumination and the radiation can be determined from a large number of experiments with a large number of eyes, so as to get the value of the function for the normal human eye. This function, however, is constant only for one source of light, or, it may be, for sources of light of the same temperature. It appears, then, that, in the first instance at least, a standard should be defined as being made of a definite material at a special temperature.

The energy required to produce a certain radiation in the case of a thin filament of carbon or platinum-iridium heated by the passage of an electric current can be easily measured by the ordinary electric methods, and the radiation may be measured by a thermopile or a bolometer, which itself can be standardised by measuring the radiation from a definite surface at 100° C., compared with the same at 0° C. The electric method measures the absorption of energy; the thermopile measures the total radiation. These two are identical if no energy is wasted in convection within the glass bulb of the lamp, by reflection and absorption of the glass, and by conduction from the terminals of the filament. Captain Abney and Colonel Festing have come to the conclusion that there is no sensible loss

Digitized by Google

from these causes. The committee propose to investigate this further. This constitutes a first research.

No research is necessary to prove that with a constant temperature of a given filament the luminosity is proportional to the radiation, because each of these depends only upon the amount of surface of the radiating filament. It will be necessary, however, to examine whether with different filaments it be possible to maintain them at such temperatures as shall make the illumination of each proportional to the radiation. This will be the case if spectrum curves, giving the intensity of radiation in terms of the wave-length when made out for the different sources of light, are of the same form. Thus a second research must be undertaken to discover whether the infinite number of spectrum radiation curves, which can be obtained from a carbon filament by varying the current, are identical in form when the filament is changed, but the material remains so far as possible of constant composition.

It will be an object for a later research to determine whether, when the radiation spectrum curve of any source of light has been mapped, a similar curve can be found among the infinite number of curves which can be obtained from a single filament.

The next step proposed is to examine a large number of carbon or of platinum-iridium filaments, and to find whether the radiation spectrum curve of different specimens of the same material is identical when the resistance is changed in all to x times the resistance at 0° C. If this law be true a measurement of the resistance of the filament would be a convenient statement of the nature of the radiation curve. If, then, a number of filaments were thus tested to give the same radiation spectrum curve, their luminosities would in all cases be proportional to their radiations, or (if there be no loss in convection, conduction, absorption, and reflection) proportional to the electrical energies consumed.

Thus it might be hoped to establish a standard of white light, and to define it somewhat in the following manner :—*A unit of light is obtained from a straight carbon filament, in the direction at right angles to the middle of the filament, when the resistance of the filament is one half of its resistance at 0° C, and when it consumes 10^9 C.G.S. units of electrical energy per second.*

Since Mr. Swan has taught us how to make carbon filaments of constant section by passing the material of which they are composed through a die, it is conceivable that another absolute standard should be possible—viz., a carbon filament of circular section, with a surface, say, $\frac{1}{100}$ square centimetre, and consuming, say, 10^9 C.G.S. units of energy per second.

Whether such standards are possible or not depends upon the experiments of the committee. The probability of success is sufficient to render these experiments desirable.

Proposed Later Experimental Researches.

Should these hopes be realised, and an absolute standard of white light thus obtained of a character which would commend it to the civilised world, it would then become an object of the committee to find the ratio of luminosity when the radiation spectrum curve of the standard filament is varied by varying the current, and consequently the resistance of the filament.

Thus, by a large number of subjective experiments on human eyes, a multiplier would be found to express the illumination from the standard lamp, with each degree of resistance of the filament.

A research, previously hinted at, would then be undertaken—viz., to find whether the radiation spectrum curves of all sources of illumination agree with one or other of the curves of the standard filament. It is not improbable that this should be the case except for the high temperature of the electric arc.

Should this be found to be true, then photometry would be very accurate, and the process would be as follows :—*Adjust the standard filament until its radiation spectrum curve is similar to that of the light to be compared.* (This would probably be best done by observing the wave-length of the maximum radiation, or by observing equal altitudes on either side of the maximum, the instruments used being a spectroscope and a line thermopile or a bolometer). The total radiation of each is then measured at equal distances by the thermopile. The resistance of the filament is measured, and its intensity in terms of the unit of white light obtained therefrom by the previous research. The luminosity of the compared source of light is then obtained directly.

The committee desire to be reappointed, and to enable them to carry out the researches indicated they ask for a grant of £30.

LEGAL.

Alleged Infringement of Edison's Patent.

In the Chancery Division, yesterday, before Mr. Justice Kay, an interlocutory application was made by the United Telephone Company against Mr. A. F. St. George, for an injunction to restrain the manufacture and sale of an instrument alleged to be an infringement of the plaintiff's patent of a telephone. Mr. Aston, Q.C., and Mr. Micklem were for the plaintiffs; Mr. G. Hastings, Q.C., and Mr. Bousfield for the defendant. At the close of the arguments,

The JUDGE said Edison's patent had been the subject of a great deal of litigation. It had been supported in its present form in an action in this country, and it had been construed in the plaintiff's favour in proceedings in Scotland. The validity of the patent was not now in question, but the owners of it sought to restrain an alleged infringement. The learned Judge described the operation of Edison's tension regulator, and quoted the remarks of Lord Justice Fry in respect to it, when he was a judge of first instance. That learned Judge decided that Edison's patent of regulator was not confined to a particular form. In the present case, instead of having a substance in itself compressible brought in contact with the diaphragm, or an incompressible substance applied to the diaphragm by means of a spring, they had applied to the diaphragm an incompressible substance, by its being placed in such a position that the effect of gravity brought it and kept it in contact with the diaphragm. The question he had to determine was whether that was substantially the same thing as Edison's patent. In the case in Scotland, what was determined to be an infringement was a diaphragm to the underside of which were attached two little rolls of carbon, against which lay the tension regulator in the form of other pieces of carbon hung up by bits of string, so that the effect of gravity was to bring them in contact. That was as nearly as possible identical with the defendant's arrangement, only in the latter case, instead of there being little rolls of carbon brought into contact with two scrolls attached to the diaphragm, there was a carbonised diaphragm, and in combination with it a little ball of carbon hung in such a way that, by the action of gravitation, it lay against the diaphragm. It had been decided by the authority in Scotland, from which he could not very readily dissent, if he did not agree with it, but with which he entirely agreed, that the form he had described was to all intents and purposes identical with, and was not substantially different from, Edison's invention. The defendant said while his instrument was in operation there was a make and brake of contact, but he did not say that by means of this make and break there was a transmission of vocal sound. On the contrary, Sir William Thomson, Mr. Imrie, and Prof. Hopkinson, stated in the affidavits that the transmission of intelligible speech was impossible while there was such make and break of electric continuity, and Mr. Hills stated that there was sometimes a blurring and buzzing sound in the instrument, but when the voice was clear and distinct there were no sparks, consequently no make and break. Where a patent had been established it was a great injury to a patentee to have people infringing his patent, and saying, "We will go on infringing the patent until the trial of the action." To his (the Judge's) mind there was no substantial question in this action for trial. On the evidence before him the conclusion was absolutely irresistible that this was a plain infringement of the plaintiff's patent. Accordingly he felt bound to grant an injunction to restrain the manufacture and sale of any more of the defendant's instruments between the present time and the trial of the action.

Mr. ASTON asked that the defendant might be restrained from advertising that he could sell.

The JUDGE said that was another matter, and was not now before him.

Provincial Brush Electric Light and Power Company v. Shillingford and Company.

In the Queen's Bench Division, yesterday, before Mr. Justice Field, an action was brought against a firm of brewers at Witney, Oxfordshire, for £53. 17s. 2d., being the balance of an account for the installation of the electric light at the brewery.

Mr. CUNNINGHAM was for the plaintiffs, and he put in the correspondence with a view to establish a contract between the parties.

The JUDGE said there was no contract disclosed in the correspondence, and the action would resolve itself into one for work done and goods supplied. The phrases occurred in the correspondence :—"We are quite willing to guarantee that the light shall be a success;" and "in guaranteeing a successful installation," &c. The plaintiffs therefore had to make out a successful installation.

Mr. J. ROSE said the plaintiffs were not to be paid unless the installation was successful, and the defendants made the following charges against it :—That the brushes and filaments wore out too rapidly; and the connection between the lamps was insufficient, and the lamps were faulty in construction. When complaint was made of the lamps, another set was supplied; and while the first set, giving a fair light, had too short a life, the next set had a longer life, but gave a very poor light. The erection of the fuses for the automatic cut-outs was careless, so that the batteries had been too highly charged and too rapidly discharged. Also the accumulators were insufficient for the current and the number of lights.

Mr. CUNNINGHAM said he admitted that at one period the lighting was not satisfactory.

The JUDGE said that being so, the question remaining to be solved was, whether the installation had been defective, or there had been a mis-user of it by the defendants.

The case was not completed at the rising of the Court.

The Maxim-Weston Electric Co. v. Thomas.

In the Queen's Bench Division, on Monday and Tuesday last, before the Lord Chief Justice and a Special Jury, a claim was made by the Maxim-Weston Company against the lessee of Covent Garden Theatre. The parties entered into a contract in July, 1884, for the lighting of the Floral Hall by 20 large arc lamps of 1,400 candle-power and 360 incandescent lamps during the continuance of the promenade concerts of 1884, for which £30 a week was to be paid. It was found that the light was insufficient, and subsequently seven additional arc lights were supplied, for which the plaintiffs now sought for payment. When the agreement was prepared the defendants asked that a guarantee should be inserted in it that the plaintiffs should give a good and efficient light, but the plaintiffs refused to sign the contract with that guarantee.

Mr. H. Watt, the plaintiff's manager, said within a week of the opening of the hall they were called upon to supply first four, and afterwards three additional arc lights, which they did, and the cost of them to the company was between £3 and £4 per week. They charged the defendant for these extra lights at the rate of £5 per week for the season of between fifteen and sixteen weeks.

Digitized by Google

Mr. WILLIS said the question was whether the extra lights were ordered under such circumstances as to make the defendant liable.

Witness said the understanding was that if the plaintiffs would make the lighting satisfactory Mr. Thomas would pay.

Correspondence was put in, which showed that the defendant repudiated having ordered extra lamps, but claimed that the original contract was that the Floral Hall should be properly lighted, and all he did was to suggest how this might be done.

At the close of the plaintiffs' case Mr. WILLIS addressed the jury for the defendant. He said differences arose between the parties about the terms of the advertisement, and ultimately they stood thus:—"The Floral Hall, the coolest and best-lighted place of amusement in Europe, illuminated by the Maxim-Weston Electric Company." The defendant wrote that it was far from being what was described. The plaintiffs wrote that the installation cost a great deal of labour, and would not pay them at a less charge than £50 a week. The defendant replied that it was idle to ask him to pay extra for what the plaintiffs contracted to do, and that he did not care what kind of lamp was employed so long as he got a proper light and was able to save gas.

The JUDGE, in the summing up, pointed out that the agreement contemplated the electric light not being sufficient, because if it had to be supplemented by gas the plaintiffs were to pay for the gas; but nothing was said in the agreement about additional electric lamps beyond the twenty arcs specified. In his opinion the defendant was not entitled to go behind the agreement of July 21st, by which both parties must be bound. He would ask the jury to answer two questions:—First, was there ever in fact an agreement between the parties that four lights beyond the twenty should be put up by the plaintiffs free of cost? And, secondly, was it ever agreed that three lights beyond the four extra should be supplied by the plaintiffs free of cost? Did the correspondence show that there ever was an independent contract or understanding that, as regarded any arcs, except those specified in the agreement, they should be included in the £30 a week?

The Jury found for the plaintiffs for £80, having answered both the questions in the negative.

Counsel asked for a stay of execution, but the Judge said there was no reason for such a step, and he gave judgment in accordance with the verdict.

Wheatley v. The Consolidated Electric Light Co.

In the Chancery Division of the High Court of Justice on Monday and Tuesday last, the hearing of this case was resumed. It was an action to restrain a nuisance of noise and oscillation occasioned by the working of the defendants' machinery upon premises separated only by a party wall from the dining room of the Three Compasses, Cow Cross-street, Smithfield.

Mr. Ingram, a consulting engineer, of Queen Victoria-street, said he visited the premises on the 23rd November, and by tests ascertained that the oscillation in the dining room corresponded with the beating of the machinery on the adjoining premises. He heard three distinct noises. The vibration was communicated to the party wall by means of the iron girders which supported the shafting. In cross-examination witness said the erection of a separate wall, as had been suggested, would diminish the area of the defendants' premises, but it would not necessitate the moving of the machinery, as the bands could be shortened.

Mr. MILLAR, for the defendants, contended that the plaintiff's business was itself a noisy one, and carried on in perhaps the noisiest spot in London. There was also noise from the neighbouring railway line, along which heavy luggage trains were constantly passing. The plaintiff went to the noises; they were not brought to him. If the noise had slightly increased, Wheatley was not the man to complain, as he was only a weekly tenant at £5 a week, the tenancy being terminable at a month's notice. He paid nothing for the goodwill, and neither the leaseholder nor the freeholder interfered in the matter. The previous tenant paid £500 a year, and died insolvent; the business was therefore derelict when the plaintiff took it, and the further falling off in the profits was due to the stagnation of trade. The machinery ran only three hours a day. He (Mr. Millar) did not deny the existence of noise, but it was not such a noise as entitled the plaintiff to damages.

Mr. G. Forbes, civil engineer, Westminster, said he visited the premises at the request of the defendants in February of this year, and found that the noise in Cow Cross street was greater than that made by the machinery. The vibration was imperceptible, except when the hand was placed upon the party wall. The plaintiff's dining room was a remarkably quiet room when no traffic was passing, and a whisper could be heard distinctly from one end of the room to the other.

Mr. Ashby, builder, said it was possible to erect a separate wall, but it was scarcely practicable, and would be very inconvenient. The walls throughout would have to be altered, and the girders would have to be cut.

The JUDGE: A gentleman told me yesterday that the noise could be stopped with eiderdown.

Witness: Possibly, but I would not use that material.

Mr. G. Offor, the manager of the defendant company, said he accompanied the directors on their visit to the plaintiff's premises, and they came to the conclusion that their was no ground whatever for the complaint.

Several other witnesses gave evidence to the same effect—that there was no nuisance whatever.

After counsel on both sides had addressed the Court,

The learned VICE-CHANCELLOR said the plaintiff had fully made out his case, that a nuisance was occasioned by the defendants' engines and dynamos. It was admitted by both sides that the traffic in Cow Cross-street and the passing trains made some noise but that was no reason why the defendants should go there and make more noise, which was heard above the neighbouring noises. It was proved by the defendants' own witnesses that the working of the machinery had created noise and vibration. The mischief could, moreover, be remedied in a few hours, if the defendants were willing to do so. There must be an injunction.

By arranyement between the parties, the order was suspended for a month.

United Telephone Company v. Townson and Mercer.

On the 27th ult., in the High Court of Justice, Chancery Division, before Vice-Chancellor BACON, Mr. ASTON, Q.C., applied for an interim injunction, on the ground that the defendants had sold a Bell telephone in separate parts, which, however, anybody could put together at any time. To sell a telephone in separate pieces was substantially to sell the patentee's telephone. A correspondence had taken place between the parties, and the defendants' solicitors had written that they would consent to the injunction, and had instructed counsel to consent also to damages, subject to a settlement being arrived at in regard to them. One of the essential clauses in the arrangement of such cases was that the costs incurred by the plaintiff up to the time of the settlement, should be paid on the scale of costs between solicitor and client. This was what he (Mr. Aston) asked in the present case.

Mr. WILKINSON, for the defendants, said he would agree to the injunction being made perpetual, but the question of costs was left by the Act in the discretion of the Judge; and he urged that the defendants should only be called upon to pay the costs between party and party. He made this offer last week, when the plaintiffs refused it, and costs had since been incurred quite unnecessarily.

The VICE-CHANCELLOR, in granting a perpetual injunction, said the policy of the Act was that if a patentee was put to the trouble of bringing more than one action, after he had established his right, the infringer should pay the solicitors' and clients' costs. That must be the order in this case.

NOTES.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 4th December amounted to £3,376.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending November 30th amounted to £3,775.

ENGLAND AND BURMAH.—Advices from Thyetmyo, dated December 9th, state that telegraph communication with the frontier will probably be restored within four or five days.

EASTERN EXTENSION TELEGRAPH COMPANY.—An interim dividend for the quarter ended September 30th of 2s. 6d. per share has been declared by this company, payable on the 15th prox.

ITALY AND THE RED SEA.—It is announced that a contract has been signed between the Italian Government and Pirelli and Co., of Milan, for laying down a cable between Massowah and Perim.

HEALTH AND THE ELECTRIC LIGHT.—Under the above title a lecture was delivered last night (Thursday) by Mr. Eric S. Bruce at the Parkes Museum of Hygiene, Margaret-street, Regent-street, W.

AT THE NEW CIRQUE.—The installation of the new Cirque Dela Rue Saint-Honoré, Paris, is being rapidly pushed forward. During the last eight days work has been carried on at night, thanks to the Edison light.

AT THE OPERA.—On Saturday last at the Paris Opera House the *loggia* was electrically lighted for the first time. The large vestibule which gives access to the grand staircase is illuminated by 10 Pieper arc lamps.

BRUSSELS.—The Special Commission deputed to examine the different systems of lighting proposed for the new council room of the Belgian Chamber of Representatives at Brussels have decided to adopt the incandescent light.

TELEGRAPH LEARNERS.—The Civil Service Commissioners notify that an examination for the Telegraph Service of the General Post Office will shortly take place, applications to be received not later than 28th inst. Age, 14 to 18.

THE ELECTRIC LIGHT AND THE NEW PARLIAMENT.—The *Standard* states that among the minor legislative proposals which have been under the consideration of the Government is one dealing with the subject of the Electric Lighting Act.

THE TELEGRAPH BATTALION.—On Wednesday evening Lieutenant F. G. Bowles, Royal Engineers, and six clerks of the Second Telegraph Battalion, received orders at Aldershot to hold themselves in readiness to proceed on service to Egypt.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 4th December were £2,576, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for November were £22,800. In the period from 1st January to 30th November the receipts were £264,440; against, in the corresponding months of 1884 and 1883, £257,480, and £236,480 respectively.

AN ELECTRIC LAUNCH FOR ITALY.—Messrs. Yarrow and Co., of Poplar, have received an order from the Italian Government for a launch, to be propelled by electricity, for Spezia Dockyard, where it will be tested specially with a view to determine the merits of this system of propulsion for torpedo boats.

ELECTRIC SIGNALLING FROM BALLOONS.—We are informed that Mr. Eric S. Bruce, whose experiments in electric signalling from balloons have been noticed in our columns, is now supplying balloon apparatus to the Government, his method having been favourably reported upon by the officials deputed to examine it.

A CORRECTION.—We learn that the information published in our last issue respecting the total destruction of the Simplex Company's works by fire is incorrect. The fire was fortunately confined to the store rooms and office; and although it has caused temporary inconvenience, will not interfere with the business the company has in hand.

VIOLENT STORM IN GENEVA.—A telegram from Geneva, dated Tuesday night, announces that a thunderstorm of remarkable violence raged there on Monday evening, accompanied by a hurricane and a deluge of rain. The lightning was magnificent, and the thunder like the discharge of a park of artillery. Considerable damage has been done by the storm.

H.M.S. "INFLEXIBLE."—A few months since a scheme for the illumination of the turret ship "Inflexible" by electricity was forwarded to the Admiralty. The plans have now been returned as rejected, owing to the unsatisfactory disposition of the searchlights and projectors. It is not suggested that any improvement to the scheme of internal lighting will be required.

PERSONAL.—We regret to notice amongst the names of the old members of Parliament who have lost their seats in this election that of Mr. John Pender, who has been defeated for the Wick Burghs by a small majority.—Capt. M. H. G. Goldie, R.E., has been appointed Instructor in Army Signalling and Telegraphy to the Sappers and Miners in the Bombay Presidency.

A NEW PRIMARY BATTERY COMPANY.—According to the prospectus of the Chemical Electric Light and Power Company, of Boston, Mass., their cells, measured after six hours' work on closed circuit, give the following results: Electromotive force = 1·6 volt, current = $5\frac{1}{2}$ amperes, internal resistance = $\frac{7}{100}$ ohms. We are not acquainted with the nature of the solution.

HURRICANE ON THE COAST OF PANAMA.—Telegrams from Panama report a serious hurricane off the coast of Aspinall. Several vessels have been wrecked, and the railroad has been damaged. Telegraphic communication is also interrupted, delaying the despatch of more precise information as to the extent of the damage. It is feared that many lives have been lost at Colon.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—We are informed that the directors of this company declared on the 9th inst. an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended 30th September last, and payable on the 24th inst. The books of this company will be closed from the 17th to 23rd inst., both days inclusive.

THE ELECTRIC LIGHT IN THE MIDLANDS.—The adoption of the electric light for the illumination of works is extending in the Midlands. Messrs. John Lysaght, Wolverhampton, have just had the whole of their extensive Swan Garden Works fitted up upon the incandescent system. Messrs. Elwell and Parker, Wolverhampton, have supplied two dynamo machines, each capable of supplying 200 lamps, of 20 candle-power.

TELEPHONE POLES WANTED.—The directors of the Lancashire and Cheshire Telephonic Exchange Company are prepared to receive tenders for the supply of larch and creosoted poles during the year ending 31st December, 1886. Forms of tender may be obtained upon application at the head office,

Digitized by Google

Manchester, and all tenders must be sent in not later than Tuesday morning, 15th inst.

BLACKPOOL.—At a recent meeting of the Blackpool Town Council the Highways Committee recommended that the Promenade be lighted by the electric light from the 24th inst. inclusive, for the succeeding ten days. The recommendation was adopted. Mr. J. Wolstenholme, borough surveyor, was formally appointed engineer of the Corporation, of and for the Blackpool Corporation Tramways, in place of Mr. T. Sunderland.

THE TELEPHONE AND RADIANT HEAT.—In a note recently presented to the Académie des Sciences, M. Mercadier submitted the results of his experiments with the action of radiant heat upon an elastic body, under the conditions of rythmic intermittence. He has ascertained that in such cases the heat rays have a sensible effect upon the diaphragms of the telephone and microphone, causing the latter to give out audible sounds.

A RAMPANT ACCUMULATOR.—In its issue of the 3rd inst. *The Times*, speaking of unelected former members of Parliament, says: "Indeed it is somewhat terrifying to think of all this power let loose from the restraining bounds of the House on it and on the community. The effect may be like the despatch of a vast dynamo accumulator, silenced by its neighbours in one quarter, to run wild about the town." This is, to say the least of it, vague.

SOCIETE BELGE D'ELECTRICIENS.—The annual general meeting of this society took place on the 1st instant, when M. Delarge, *ingénieur en chef directeur des télégraphes*, was unanimously elected president in the room of M. Rousseau. After the secretary, M. Charles Mourlon, had reported upon the proceedings of the society during the current year, the following gentlemen were elected members of council:—MM. Bède, Collard, De Cazenave, Bouquié, Lebègue, Northomb, Rousseau, Van der Mensbrugghe and Wybauw. The number of members of the society is now 253.

INGREY, POORE AND LATHAM (LIMITED).—This is the conversion to a company of the business of electric engineers, agents, and merchants, and electric light apparatus contractors, carried on by Charles Ingrey and Graydon Poore, at 49, Queen Victoria-street. It was registered on the 20th ult., with a capital of £4,000 in £10 shares, with power to increase. An agreement of the 17th ult. regulates the purchase, the consideration being £2,500 in fully paid shares and a sum in cash not exceeding £150 in payment of debts due by the vendors up to the 1st October. Registered without special articles.

THE EASTERN TELEGRAPH COMPANY.—This company announce the payment on 14th January next of interest at the rate of 3s. per share on the preference shares of the company, less income-tax, for the quarter ending 31st December, 1885; and that on the same day an interim dividend will be paid of 2s. 6d. per share in respect of profits for the quarter ended 30th September, 1885, with a bonus of 1s. per share for the half year ending at that date, on the ordinary shares of the company, both free of income-tax. The register of transfers will be closed from the 6th to the 14th January, 1886, both days inclusive.

POST OFFICE ORPHAN HOME.—The annual concert in aid of the funds of this deserving institution will take place tomorrow evening, in St. James's Hall, under the conductorship of Signor Alberto Randegger. The entertainment, which is of such an ample description that it is announced to commence at a quarter to eight, is under the patronage of the Dukes of Edinburgh, Cambridge, Teck, Norfolk, and Bedford, the Earl of Derby, the Postmaster-General, the Lord Mayor, and a number of the officials of the Post Office. Tickets (by which alone admission can be secured) are to be obtained of the secretary, Mr. J. Avery, E.C.D.O., General Post Office, and from members of the institute. The manager is Mr. W. Henfrey, Post Office, Vere-street, W.

BOOKS RECEIVED.—"Inventions and How to Patent Them: A Practical Guide to Patentees." By T. Eustace Smith. London: W. H. Kelly. The object of this book is to place clearly before an inventor all the information that is necessary to protect his invention and to become his own patent agent. "Calvert's Mechanics' Almanack and Workshop Companion for 1886." London: John Heywood. Contains, in addition to the usual matter of an almanack, practical, technical, an industrial information especially instructive and entertaining to artisans and handicraftsmen and those generally engaged in mechanical, engineering, building, and constructive trades, &c. The almanack is well illustrated, and will be found to be a handy little work.

THE TELEPHONE IN MINES.—The Northern District Telephone Company of Sunderland have issued a circular in which they say:—"This company, taking into consideration the great number of collieries situated in the district for which they hold their license, and feeling the great importance of efficient telephonic communication in mines, have decided to supply instruments for this purpose at exceptionally low rates. The great utility of these instruments in cases of accidents has been amply demonstrated at Usworth Colliery, and during the flooding of the Margaret Pit. The value of instantaneous communication between, for instance, the manager's house and the colliery office, and from the colliery office to the bottom of the shaft and the various parts of the workings can hardly be over-estimated."

THE ELECTRICAL CONDITION OF THE HUMAN BODY.—M. Wolff, who has recently published in the *Deutsche Médicinische Wochenschrift* an article upon a new application of electricity to the diagnosis of certain diseases, concludes that the presence of a quantity of liquid in the human body has a very sensible effect upon its resistance. He cites the case of a person suffering from pleurisy in its most violent form. The side affected gave a much larger deflection, or in other words had a lesser resistance than the other. Another observation of M. Wolff's which is not without its value is that, of all parts of the body, the cheeks are the best conductors of electricity, and that the palms of the hands and the soles of the feet are greatly inferior to them in conductive value. It would be interesting to learn the conditions under which M. Wolff made his observations.

INDIGNANT.—Our excellent contemporary, *Electricité*, feels that we are neglecting M. Marcel Deprez. It says:—"The brothers Rothschild are about to make arrangements for the exploitation of the wonderful discoveries of M. Deprez. *The obscure and envious electricians* who for a long time past have been attempting to negative the importance of the experiments at Creil, and who have declared their realisation impossible, must now admit that the transmission of force is a *fait accompli.*" The daily papers also state that Messrs. Rothschild Brothers have officially notified to the French Syndicate of Electricity that they have resolved to form a company for working the newly invented system of transporting force by electricity. The success of the recent experiments between Creil and Paris has, it is understood by our contemporaries, led to this resolution.

SIMULTANEOUS TELEGRAPHY AND TELEPHONY IN FRANCE. The telephonic service between Paris and Rheims was opened, as before announced, on the 1st inst. The lines which are connected with the telegraphs are two in number, permitting of two distinct and simultaneous telephonic communications. At Paris offices other than that at the Bourse are not yet established, but at Rheims communication is maintained from ten different places. One of the telephone circuits is composed of two aerial lines of a diameter 4mm., and of 8 kilometres (4·96 miles) of cable; the other circuit consists of two aerial lines 5mm. diameter, and a cable of the same length as before. The length of the aerial lines is 172 kilometres (106·64 miles) of wire; the cable carries the line to an effective distance of 217 kilometres (134·54 miles), so that in the circuit there is a total of 434 kilometres (269·08 miles) of line. The Van Rysselberghe system is employed.

EARTHQUAKES.—Earthquake shocks were felt on the night of the 3rd inst. and early on the morning of the 4th inst. in Algeria, the direction of the oscillations being from north to south. Light at Algiers and on the coast, the movement became more pronounced in the interior of the country, particularly at Blidah, Menerville, Aumale, Boghara, and Boussada. At the two last-named places several houses were wrecked. At Medeah the shocks, which were very violent, lasted some time. Thirty-two persons were killed by the fall of houses at Msilah, and the residence of the chief official at Bordi-Serpant was wrecked, burying several Europeans under its ruins. Again, on Saturday, five distinct shocks of earthquake occurred at Boussada, destroying the Presbyterian Church and seventy-one dwellings. Two persons were killed, and two others received injuries. Advices from Paris state that four new shocks of earthquake were felt on Wednesday at Msilah, in Algeria, the town which suffered so severely from the same cause last week.

NEW YORK UNDERGROUND WIRE COMMISSION.—In view, says an American contemporary, of the many complaints that are being made of the dilatoriness of the commissioners appointed to enforce the Underground Wire law, the Mayor recently wrote to the Corporation counsel, asking if, in his opinion, the amendments passed by the last Legislature extended the time for putting the wires underground, and also whether the city authorities had any power to act in the matter. It will be remembered that by the original Act all electric wires were to be placed underground by 1st November last. The Corporation counsel thinks it very doubtful whether it was the intention to extend the time fixed by the original Act. He says:—"This statute will undoubtedly have to be construed by the Courts," and adds that the city authorities are relieved from all responsibility of enforcing the Act. The appointment of commissioners entirely unfitted for the work before them is a misfortune to the public, to say the least, and it is still more unfortunate that there is no authority to whom these men are immediately accountable.

THE ELECTRIC LIGHT FOR LANTERNS.—An incandescent electric light, worked by a battery possessing a reasonable degree of portability, has been successfully applied to lantern illumination. At a recent meeting of the Camera Club, the hon. secretary exhibited an application of the electric light which, in that particular respect, has been frequently attempted before, but never successfully so. The batteries occupied a box, rather under 2ft. in length and half that width, upon which a pair of lanterns was erected. This box protected two cells, and in these were immersed a number of plates of zinc and carbon, the mechanical arrangement being such as to provide for their being lifted quite out of the fluid and again immersed at pleasure. Each lantern was fitted with a somewhat small incandescent lamp, and when, upon pressing a button, the circuit was completed, the carbon filament enclosed instantly responded by emitting a powerful light. This light, while inferior to that produced by oxyhydrogen, was of sufficient intensity to serve every requirement in parlour demonstration; and although its exhibition partook of a tentative character, yet were the results of an exceedingly satisfactory nature.

ROYAL INSTITUTION.—At the general monthly meeting of the members, held on Monday, the following lecture arrangements were announced:—Six lectures (adapted to a juvenile auditory) by Prof. Dewar on "The Story of a Meteorite;" three lectures by Professor Ball on "The Astronomical Theory of the Great Ice Age;" three lectures by Mr. R. Stuart Poole on "Naucratis;" three lectures by Mr. C. T. Newton on "The Unexhibited Portion of the Greek and Roman Sculptures in the British Museum;" six lectures by Prof. Gamgee on "The Function of Circulation;" four lectures by Prof. Roberts-Austen on "Metals, as Affected by Small Quantities of Impurity;" four lectures by Prof. Boyd Dawkins on "The Ancient Geography of Britain;" four lectures by Prof. Tyndall on "Light;" four lectures by Mr. A. Geikie on "The History of Volcanic Action in the British Isles;" two lectures by the Rev. C. Taylor on "The History of Geometry;" two lectures by Mr. E. B. Poulton on "The Nature and Protective Use of Colour in Caterpillars;" two lectures by Mr. H. Grubb on "The Astronomical Telescope;" and two lectures by Prof. Oliver Lodge on "Fuel and Smoke."

A HIGH-SPEED ENGINE.—During the last year or two it has come to be generally understood that large machines, driven at a comparatively low speed, were the best for electric lighting purposes; but the lighting at the Lincoln's Inn Dining Hall and Library must be considered as an exception to this rule. The dynamo here is driven, at no less than 12,000 revolutions per minute, by a Parsons high-speed engine, which justifies its title by running at the same rate. It requires some mental effort to take a statement of this kind seriously; yet there is no reason to regard the Parsons motor as a toy. It was shown in action at the Inventions Exhibition, running with unimpaired steadiness from the commencement to the close of the show. It is, in reality, a combination of turbines driven by steam, and consists of two series of parallel flow turbines to the right and left of a central steam inlet; the steam exhausting directly from the first turbine into the second, from the second into the third, and so on through twenty turbines in each series. The steam parts with a portion of its energy in each turbine, and finally escapes at a pressure not much above that of the atmosphere. It is claimed that this is the first motor that has ever been made to work at the actual velocity of the steam as it escapes from the boiler.

THE WIRT BATTERY.—The Wirt cell is a modification of the Daniell. It is so constructed that the fluids cannot become disturbed or mixed through any slight jarring, and consists of three square bottles, 1¼ square inch by 4½in. high, with a neck ⅝in. in diameter by 1in. long, securely clamped together at the top and bottom. In the upper part of the adjoining sides of bottles I. and II. is drilled a small hole ⅜in. in diameter, and in the lower part of the adjoining sides of bottles II. and III. are similar holes, all arranged to correspond with each other. A soft rubber washer separates the bottles at the holes, making a water-tight joint, and also acting as a support to hold in place a thin film of goldbeater's skin, through which

Digitized by Google

the liquids must pass, by the process of endosmose and exosmose, from one bottle to the other. All of the bottles are filled with a dilute solution of sulphate of zinc; within bottle I. is placed a piece of sulphate of copper about the size of a pea, which changes the solution to a blue colour; the copper electrode at the bottom is connected by an insulated wire, which passes through the cork. At the bottom of bottle II. is a small piece of zinc which collects any deposit of sulphate, should any pass through from bottle 1. In the top of bottle III. is suspended the zinc electrode, which measures about 1⅛in. long by ¾ wide and ⅛ thick. This arrangement is supposed to give a very constant battery which cannot polarise, as each electrode is completely isolated, and the separation of the bottles with the goldbeater's skin also prevents an easy mixture of the solutions.

Soudan Medals.—The medals awarded to the Grenadier Guards and the Army Postal and Telegraph Corps, attached to the 24th Middlesex (Post Office) Rifle Volunteers, for service in the late campaign in the Soudan were presented a few days ago to the officers, non-commissioned officers, and men entitled to the honour, on the parade ground of Wellington Barracks, in the presence of a full attendance of both regiments and a large number of spectators. The 3rd Battalion of Grenadier Guards, under the command of Colonel Thynne, C.B., and the Post Office Rifles, under Colonel Du Plat Taylor, were formed up in column, and, prior to the presentation, were addressed by Colonel Philip Smith, who, in a few appropriate words, congratulated first of all the Grenadiers on the opportunity which had been afforded them of serving their country in war and gaining distinctions denied to older soldiers. Addressing the detachment of volunteers, Colonel P. Smith expressed the gratification he felt in welcoming back Major Sturgeon and the non-commissioned officers and men who had formed part of the Postal and Telegraph Corps, and had rendered the State a most important and valuable service. There was nothing more benefiting to the soldier in time of war than prompt and correct telegrams and the anxiously anticipated letters from home, the duties with regard to which were so admirably carried out by the men who had volunteered, and throughout the campaign had performed in Her Majesty's service a most important duty. The medals were then distributed, after which the parade was dismissed.

Old Students' Association.—On Tuesday, the 1st inst., the second general meeting of the City and Guilds of London Finsbury Technical College Old Students' Association took place at the Finsbury College. The proceedings of this association (which has for its object the promotion of social intercourse among its members, and the encouragement of their interest in the welfare of the college) consisted of a presidential address by Mr. H. Newman Lawrence, a late student, and the reading of a paper on "Opacity," by Prof. Silvanus Thompson, B.A., D.Sc., the Principal of the College The President, in an interesting address, pointed out a few of the lines on which the attainment of the objects might be arrived at. He volunteered to keep a register of technically educated students requiring suitable employment, and of employers of scientific labour requiring assistants, &c.; he also proposed to establish a system of correspondence between members desiring to obtain and those willing to give information on special subjects; he also suggested that the usual monthly meetings should not only consist of the the hearing and discussing of technical papers, but should be varied with concerts and even dances, and thus produce real, social intercourse. He, in the finish of his address, said that he was quite confident that though the present association only consisted of about seventy members and had to borrow rooms for its meetings, it would in a short time have its own rooms, laboratories, and library, as well as a recognised position among the older scientific societies. Prof. Thompson, in his paper on "Opacity," dealt with the electro-magnetic theory of light, and exhibited his collection of tourmalines, the electrical and optical properties of which stones are well known. He also showed an artificial tourmaline of his own design, constructed of layers of glass and wire gauze, having all the electrical and optical properties of the real stone. The proceedings terminated with an announcement of a concert, to take place early in January.

The Telephone and the Opera.—There is some talk, says the *Daily News*, of a new telephonic enterprise which will far surpass all we have lately heard from Rheims. Wires are to be laid on at the Opera, and the music brought, not exactly into our houses, but into a public hall, where the passer-by may take a shillingsworth of Covent Garden just for curiosity. There is warrant for it; during the Electrical Exhibition in Paris the Palais de l'Industrie was connected with the Grand Opera in this way. A room was filled with telephonic ear trumpets, and the crowd was so great that every tube holder had to be limited to the short lease of ten minutes. Something was heard, and heard fairly well, when the orchestra was in full blast; but in the vocal parts all but the soprani came out a mere subterranean rumble. It was chronicled at the time as prima donna by telephone, and it served to make money, which will probably be the only purpose of any new scheme of the kind. Writing to a contemporary upon this subject, the general manager of the National Telephone Company says:—"It may be of interest to learn that the 'new' telephonic enterprise projected at Rheims has been an accomplished fact in Scotland for at least two years past. Subscribers to this company's Dundee, Broughty Ferry, Newport, Perth, Forfar, and Arbroath Exchanges are, on demand, switched on to the Dundee Theatre Royal while a performance is proceeding, and, by means of transmitters fixed near the orchestra, are enabled to hear the music, dialogue, applause, &c., in their own offices or homes. The privilege is very frequently taken advantage of. The general public are not excluded. Any person, by going to one of the company's call-offices in any of the above-named towns, and paying the usual small fee, may enjoy the distant performance equally with subscribers. This comprises all that is proposed to be done in France, so the claim to novelty is certainly (if not without Rheims) without reason. Similar arrangements could be made in Edinburgh, or any other town where the company possesses an exchange, if the subscribers wished and the theatre lessee were willing."

Secondary Battery Litigation.—The decision given some time ago by the Examiners-in-Chief of the United States Patent Office in the case of Sellon *v.* Hochhausen has been appealed against. The application of J. S. Sellon was filed July 14, 1883, and the application of W. Hochhausen on June 21, 1883. Haid, who was a third party to this interference, dropped out of the case, and was not a party to this appeal. The decision was as follows:—"In interference proceedings, where neither applicant files a preliminary statement, the senior applicant will, under Rule 111, be *presumed* the first inventor, and priority awarded him. In such cases where the invention in controversy is disclosed in the application of the senior applicant priority cannot be awarded the junior applicant, even though such senior applicant expressly disclaims, for the present, any claim to a patent for such disputed invention. In such interference cases priority must also be awarded such

Digitized by Google

senior applicant, notwithstanding the oath of the junior applicant discloses the fact that he has received British patent for his invention which antedates the time of the filing of either application." In summing up the case the Commissioner of Patents said :—" It might be admitted for the purpose of this controversy that Sellon actually had an English patent which antedated the filing of Hochhausen's application, and it could make no difference with the award in this case. If it were admitted that Sellon's English patent issued and bore date three months anterior to the filing of Hochhauson's application, still that would come far short of proving that Sellon was the inventor of the thing which he patented in England. The issue of an English patent is by no means evidence that the patentee is the inventor, as in that country patents are issued not only to inventors but to importers of inventions. Independent of this, however, I have no hesitation in declaring that priority must be awarded upon this record to Hochhausen. The argument of counsel for Sellon was ingenious and exhaustive. Upon reflection, however, there is nothing else to do but to affirm the decision of the Board. It is perhaps to be regretted that a case of this kind should be permitted to go off upon such a question. If Sellon really has a meritorious claim to be regarded as the first inventor, it is to be regretted that he has not attempted to show it by his proof. It is sufficient for me, however, that he has not done so, and I must dispose of the case as it comes to me."

Small Installations in Somersetshire.—The large Reading Room of Horsington, Somersetshire, was lit up for three nights last week by ten Woodhouse and Rawson 20 candle-power lamps at a *conversazione* and exhibition held there, the current being obtained from a battery of accumulators 160 yards off, at the residence of the Rev. J. D. C. Wickham, and conducted by a bare copper cable hung on insulators, an iron water-pipe being used for the return lead. The lights were perfectly steady, and showed off the various exhibits, especially the pictures, to great advantage, besides being very convenient for the purposes of such an entertainment, owing to their capability of being lowered or put out as occasion required. Other uses of electricity were also exemplified by an arc lamp, used in a magic lantern, and supplied by a Griscom motor, which also worked a sewing machine ; by an induction coil, which illuminated vacuum tubes; by Edison's electric pen, which was exhibited during a short lecture upon his life by a gentleman present; and by a tone telephone, which conveyed music into the room from a distant and invisible source. This was kindly lent by Messrs. Paterson and Cooper, of London. The Rev. J. D C. Wickham, under whose directions the installation was put down, has lit his house completely with Swan 10 candle-power lamps for some time past. Accumulators supply the current, and have hitherto served him well, increasing rather than deteriorating in efficiency. He has two batteries, one of E.P.S. Co.'s cells, the other of Messrs. Elwell and Parker, capable of working independently when each lights a moiety of the lamps; or of being combined in series for charging, or when a higher E.M.F. is required, as, for instance, for experimental work. The main leads from the battery are carried to terminal screws upon a board in the hall, to which the branch wires are also led. The lamps have mostly their separate switches coated with luminous paint, so as to be easily found in the dark. Cardew's voltmeter and Ayrton and Perry's spring ammeter are used as measuring instruments, and are found very reliable. In spite of some difficulties, such as, for instance, the adjustment of the brushes of the dynamo, and the determination of the amount of charge in the accumulators, Mr. Wickham finds the work of domestic electric lighting fairly within the capabilities of an amateur, and though the first cost has been considerable, and the attention necessary rather irksome, this is made up for by the cheerfulness, beauty, and convenience of the light, and by the unfailing interest which the supervision of his small installation affords.

City and Guilds of London Institute.—At the quarterly meeting of the council the Earl of Selborne, chairman of the council, made an appeal to the City and Livery Companies of London to subscribe the necessary funds to complete the work of organising a national system of technical education, on the success of which, he said, the commercial prosperity of the country so greatly depended. He referred to the large sums of money which the companies had already contributed, but at the same time he compared the smallness of the whole amount asked for by the Institute with the total corporate income of the companies, and pointed out that by liberally subscribing the funds now needed, the City Guilds would deserve, and he hoped obtain, the permanent gratitude of the nation. On Wednesday night a presentation of prizes and certificates took place in the Salters' Hall, St. Swithin's-lane, City. The Lord Mayor presided, supported by Alderman Sir Robert N. Fowler, Bart, M.P. ; Mr. John Watney, Mr. Owen Roberts, honorary secretaries ; and Mr. Philip Magnus, director and secretary of the institute ; the masters of several of the livery companies, Profs. Armstrong, Ayrton, Henrici, Unwin (of the Central Institution), S. P. Thompson, Perry, Meldola, and Mr. Brophy, of Finsbury Technical College ; Mr. Sparkes, of the South London School of Technical Art ; Colonel Donelly, R.E., of the Science and Art Department ; Mr. L. L. Cohen, M.P.; Sir George Young, Bart. ; Captain Galton, Professor Leone Levi, and Sir Sherston Baker. The reports were read by Mr. John Watney and Mr. Owen Roberts (hon. secretaries), of the Central Institution, Exhibition road, South Kensington ; the Finsbury Technical College, and the South London School of Technical Act. These documents showed a general increase in the number of students under instruction. A report as to the technological classes stated that the total number of students in attendance at them was 6,396, as compared with 5,874 in the year previous ; and there were 7,600 students preparing for the examinations in May next, or 552 more than in the previous year. These numbers did not include those at the institute or technical colleges, nor students of university rank. Nothing, perhaps, better indicated the spread of the influence of the institute than the fact that at the present time there were 321 classes in 162 different centres in the United Kingdom. At intervals between the reports being read the successful students, amongst whom were not a few ladies, were presented with their prizes and certificates by Sir Robert N. Fowler, Bart, M.P. The following were the principal prize-takers :—The Albany Scholarships of £50, given by the Corporation of London in memory of the late Duke of Albany, won by A. E. Rossiter and M. H. Crompton ; the Siemens Memorial Scholarship of £50, founded by Lady Siemens in memory of the late Sir William Siemens, C. Priest; the Mitchell Scholarship of £30, given by the Mitchell Trustees, A. Chatterton and W. Heller; the Clothworkers' Company Exhibition of £60, tenable for a period of the full curriculum of three years, W. E. Sumpner. The foregoing relate to the Central Institution ; the following to the Finsbury College :—The Mitchell Scholarship, J. E. Kupli ; the Saddlers' students were W. B. Clarke, J. W. Jones, A. E. Richardson, and J. R. S. Court, and the Holl scholar was J. M. Smith. An address by Sir Robert Fowler, Bart., M.P., concluded the proceedings.

[ERRATA IN LAST.—Line 25th, *for* three *read* six. Formula (111); multiply the left member by 4π. Also, cancel (112), and substitute

$$\left.\begin{aligned} 8\pi(\mathrm{U}-\mathrm{T}) &= \Sigma(\mathrm{E}c\mathrm{E}-\mathrm{H}\mu\mathrm{H}), \text{ through volume,} \\ &= \Sigma\mathrm{N}(\mathrm{VEH}'-\mathrm{VE'H}) \text{ over surface.} \end{aligned}\right\} \quad (112)$$

the accent denoting differentiation to n. Test by the convergence theorem.]

Remarks on Normal Electromagnetic Systems. Conditions of Possibility of Oscillatory Subsidence. Equal Roots, and their Effects.

In the last section I omitted to define the three symbols, U_{rr}, T_{rr}, and Q_{rr}, except by implication. They express the *doubles* of the potential energy, kinetic energy, and dissipativity of the rth normal system E_r, H_r; being quantities formed in the same manner as Q_{12}, U_{12}, and T_{12}, defined just after equation (105).

As a preparation for what follows it will be useful to bear in mind the general character of the subsidence to equilibrium of a displaced elastic body, which, for our purpose, may be simply a stretched elastic thin wire fixed at its ends. Let it be bent into the form of the arc of a bow, or, more accurately, into the form of the sinusoidal curve, and then be left to itself. If there be no resistance the wire will go on vibrating for ever with uniform frequency, always preserving the sinusoidal form. But if there be resistance to its motion, proportional at every moment to its speed, its amplitude of vibration will continuously decrease, although the frequency (lowered) will be still uniform. By a sufficient increase in the coefficient of resistance (say, by motion in a viscous fluid), we shall ultimately stop the vibrations, the displaced wire returning to, but never crossing its equilibrium position. The displacement at time t in the original frictionless vibration was represented by

$$(a_1 \sin + b_1 \cos)\, c_1 t.$$

Friction makes it

$$\epsilon^{-c_2 t}(a_2 \sin + b_2 \cos) c_3\, t,$$

showing the oscillatory subsidence to equilibrium. When, by sufficient increase of resistance, the oscillations are just stopped, it is

$$\epsilon^{-c_4 t}(a_3 + b_3 t)$$

and finally, further increase makes it

$$a_4 \epsilon^{-c_5 t} + b_4 \epsilon^{-c_6 t}$$

the sum of two independent non-oscillatory subsidences.

In general, if inertia be altogether negligible, but not elastic yielding, or the friction, there can be no oscillations. Similarly, if the elastic yielding be negligible, but not inertia and friction, there can be no oscillations. To have oscillations we require both inertia and elastic yielding; besides that the resistance must not be too great.

Coming now to the electro-magnetic applications, we shall expect the subsidence of normal systems to come under these four types. If there be no elastic displacement, and therefore no potential energy, the subsidence of a normal system must be non-oscillatory; and it must be real subsidence, not indefinite increase according to the same law. Similarly, if there be no inertia ($\mu = 0$, no magnetic induction, no magnetic or kinetic energy), the subsidence must also be real and non-oscillatory. But if neither elastic displacement nor inertia be negligible, there will be either non-oscillatory or oscillatory real subsidence, according to the relative importance of the resistance. In these three cases there is supposed to be always resistance. But if there be none, but only elasticity and inertia to consider, the normal systems will be simple harmonic with respect to the time, and go on vibrating for ever. Cases in which two of the three quantities c, k, and μ are non-existent, scarcely belong to the present subject. And the fourth case above (vibrations in dielectric media, with *no* dissipativity) does not occur in ordinary problems, as it requires unrealisable conditions.

Now, the equation of activity of a normal system is

$$2n(\mathrm{U}+\mathrm{T}) + \mathrm{Q} = 0,$$

where $\mathrm{U} = \Sigma\mathrm{E}c\mathrm{E}/8\pi$, $\mathrm{T} = \Sigma\mathrm{H}\mu\mathrm{H}/8\pi$, $\mathrm{Q} = \Sigma\mathrm{E}k\mathrm{E}$. Here E and H constitute a normal system, E being a solution of (110) and H derived from it by the second of (109); or else H being a solution of the H equation corresponding to (110), and E derived from it by the first of (109). [If there be no inertia, the electric force is polar. Then the single scalar, the electric potential, will serve for variable.]

If n be real, the normal functions E and H are real, or may be so chosen as to be real. Then also Q, U, and T are real. Further, it is necessary in the electro-magnetic applications that they cannot be negative. This is secured by the angle between a force and a flux being less than 90° at the most.

[$c = 0$.] First, ignore elastic displacement. Then $c = 0$, U is non-existent, and

$$2n\mathrm{T} + \mathrm{Q} = 0.$$

We see at once that if n be real, it must be negative. If then we show that it cannot be imaginary, we prove that all the n's are real and negative, when c vanishes, but not μ and k. Thus, if i stand for $(-1)^{\frac{1}{2}}$, let

$$n_1 = a + bi, \qquad n_2 = a - bi,$$

be a pair of imaginaries. They turn H into $\mathrm{L} + \mathrm{M}i$ and $\mathrm{L} - \mathrm{M}i$ respectively, and E into $\mathrm{L}_1 + \mathrm{M}_1 i$ and $\mathrm{L}_1 - \mathrm{M}_1 i$ respectively, L, M, &c., being real. Using n_1, the expressions for T and Q become

$$\left.\begin{aligned} \mathrm{T} &= \Sigma\,(\mathrm{L}\mu\mathrm{L} - \mathrm{M}\mu\mathrm{M} + 2i\mathrm{L}\mu\mathrm{M})/8\pi \\ \mathrm{Q} &= \Sigma\,(\mathrm{L}_1 k\mathrm{L}_1 - \mathrm{M}_1 k\mathrm{M}_1 + 2i\mathrm{L}_1 k\mathrm{M}_1) \end{aligned}\right\}$$

Using these in the equation of activity, with $n = n_1$, and separating the real from the imaginary parts, we get

$$0 = \Sigma\{2a(\mathrm{L}\mu\mathrm{L} - \mathrm{M}\mu\mathrm{M}) - 4b\mathrm{L}\mu\mathrm{M} + 8\pi(\mathrm{L}_1 k\mathrm{L}_1 - \mathrm{M}_1 k\mathrm{M}_1)\}$$
$$0 = \Sigma\{2b(\mathrm{L}\mu\mathrm{L} - \mathrm{M}\mu\mathrm{M}) + 4a\mathrm{L}\mu\mathrm{M} + 16\pi\mathrm{L}_1\mu\mathrm{M}_1\}$$

But also, by the conjugate properties in $(108)_1$, we have the mutual T and Q of the two systems n_1 and n_2 both zero;

or $\qquad \Sigma(\mathrm{L}\mu\mathrm{L} - \mathrm{M}\mu\mathrm{M}) = 0, \qquad \Sigma(\mathrm{L}_1 k\mathrm{L}_1 - \mathrm{M}_1 k\mathrm{M}_1) = 0$;

the imaginary parts cancelling. These bring the previous equations to

$$b\Sigma\mathrm{L}\mu\mathrm{M} = 0, \qquad a\Sigma\mathrm{L}\mu\mathrm{M}/4\pi + \Sigma\mathrm{L}_1\mu\mathrm{M}_1 = 0.$$

From the first of these we conclude that $b = 0$, unless L and M are the magnetic forces of two normal systems, which is not the case here. The imaginary parts are therefore non-existent, which brings us to

$$n_1 = a, \qquad n_2 = a, \qquad \mathrm{T} = 0, \qquad \mathrm{Q} = 0.$$

What we wanted to show was that imaginaries could not exist. In addition, we show that if there be a pair of *equal* n's, they will make the kinetic energy and the dissipativity of the (equal) normal systems both zero. The only way this can happen, T and Q being the sum of quantities that cannot be negative, is for each of their elements to vanish, and, therefore, $\mathrm{E} = 0$, $\mathrm{H} = 0$. That is, if n be double (or repeated any number of times), that value of n will make the normal functions vanish over all space.

[$\mu = 0$.] Next, ignore magnetic induction. Then $\mu = 0$, T is non-existent, and

$$2n\mathrm{U} + \mathrm{Q} = 0.$$

We can show that the n's are all real and negative, excluding oscillatory subsidence, and that the first conditions of a repeated n are

$$\mathrm{U} = 0, \qquad \mathrm{Q} = 0.$$

which necessitate the vanishing of the normal functions for that value of n. But, owing to the peculiarities arising from the division of space into conducting and non-conducting regions, the matter cannot be shortly treated, and will be returned to.

[c, k and μ.] Take next the general case of T, U, and Q all existent. Write the activity equation thus,

$$2n^2(\mathrm{U}+\mathrm{T}) + n\mathrm{Q} = 0,$$

Digitized by Google

and solve as a quadratic. Then,

$$n = \{-Q \pm (Q^2 - 4n^2UT)^{\frac{1}{2}}\}/4U,$$
$$n = \{-Q \mp (Q^2 - 4n^2UT)^{\frac{1}{2}}\}/4T,$$

Remembering that if n is real, Q, U, and T are all positive (if not zero), we see that $Q^2 > 4n^2UT$, or $Q^2 > \dot{U}\dot{T}$, or the dissipativity greater than the geometrical mean of the rates of decrease of the potential and kinetic energies, must be true. And n is negative. The limit of reality is reached when $Q^2 = 4n^2UT$; or

$$U = T, \qquad 4nU + Q = 0, \qquad 4nT + Q = 0.$$

Thus $U_{12} = T_{12}$, the general conjugate property of two normal systems (n_1 and n_2) when they are unequal, is also true when they are equal, *i e.*, when n is a double root of the determinantal equation of n. This includes the previous special cases of either $c = 0$, or else $\mu = 0$. Further information regarding imaginary n's may be obtained by separating the real from the imaginary parts in the above.

[$k = 0$.] When we take $k = 0$, in the equation of the normal E functions, we have

$$\text{curl}.\mu^{-1}\text{curl}.E + cn^2E = 0; \quad \mu nH = -\text{curl}.E; \quad . \quad . \quad . \quad (113).$$

If, on the other hand, we take $c = 0$, we have an equation for E of the same form, but containing n instead of n^2. Hence the same normal functions serve in both cases, if $4\pi kn$ and cn^2 be exchanged. Former conclusions regarding n in the case $c = 0$ are therefore now true of n^2. That is, every n^2 is real and negative, making the n's pairs of oppositely signed equal imaginaries, as

$$n_1 = ai, \; n_2 = -ai; \; n_3 = bi; \; n_4 = -bi; \; \&c. \quad . \quad . \quad . \quad (114).$$

where a, b, &c., are real, indicating simple harmonic oscillations without subsidence.

The property $U_{12} = T_{12}$ is true for any two roots, whether naturally associated or not; *i.e.*, for n_1 with respect to all the rest, including its companion n_2, whose square is the same. But also, the second and third conjugate properties (106), keeping in the $(n_1 - n_2)$ factor there omitted, are

$$(n_1^2 - n_2^2)U_{12} = 0; \qquad (n_1^2 - n_2^2)T_{12} = 0;$$

hence $U_{12} = 0 = T_{12}$, except if $n_1^2 = n_2^2$; that is, in case of the naturally paired n's. Also, the equation of activity becomes

$$U + T = 0,$$

for every single root n.

As the first of (113) contains n^2, if we take the E normal functions from it, they will be identical in pairs, $E_1 = E_2$, $E_3 = E_4$, &c., for the roots (114).

But then the second equation (113) shows that the corresponding H functions are the negatives of one another in pairs, thus $H_1 = -H_2$, $H_3 = -H_4$, &c. Thus the expansions of E_0 and H_0, the initial states of electric and magnetic force, become

$$E_0 = (A_1 + A_2)E_1 + (A_3 + A_4)E_3 + . \; . \; . \; ,$$
$$H_0 = (A_1 - A_2)H_1 + (A_3 - A_4)H_3 + \; . \; . \; . \; .$$

The mutual potential energy of any two double normal systems is zero, and the same is true of the mutual kinetic energy. We therefore have

$$\Sigma E_0cE_1 = (A_1 + A_2)\Sigma E_1cE_1,$$
$$\Sigma H_0\mu H_1 = (A_1 - A_2)\Sigma H_1\mu H_1;$$

giving A_1 and A_2 in terms of the initial state E_0, H_0. Using these, and putting the solutions in the appropriate real form, taking $H_1i = M_1$, $H_3i = M_3$, &c, we find that

$$\left.\begin{aligned} E_0 &= \frac{E_1}{\Sigma E_1cE_1}(\Sigma E_0cE_1 . \cos - \Sigma H_0\mu M_1 . \sin)\,at + . \; . \; . \\ H_0 &= \frac{M_1}{\Sigma E_1cE_1}(\Sigma E_0cE_1 . \sin + \Sigma H_0\mu M_1 . \cos)\,at + . \; . \end{aligned}\right\}$$

express the values of E_0 and H_0 at time t later.

The proof that there cannot be any imaginary n^2's requires some modification from the proof of absence of imaginary n's in the case $c = 0$, owing to the changed conjugate properties. It also shows that a repeated n^2 makes the normal functions vanish. [*See* Thomson and Tait on "Cycloidal Motion with no Dissipative Forces.]

[Equal roots.] This remarkable property of the vanishing (with equal roots) of the normal functions in case any one of the three c, k, and μ is zero, is closely connected with another property, viz., that of shutting out the $t\epsilon^{nt}$ term from the solutions. Looking to the formulæ at the commencement of this section, we see that on the boundary between oscillatory and non-oscillatory subsidence we have, instead of the form $a_1\epsilon^{n_1t} + a_2\epsilon^{n_2t}$, that of $(a + bt)\,\epsilon^{nt}$. Also, when by a change in the value of some constant, two roots are made to approach one another, and then again diverge imaginary, between the two states we have a pair of equal roots. If, then, the oscillatory form of solution is possible we have the $t\epsilon^{nt}$ term on the very verge of oscillation. Now, in certain cases we know that oscillations are impossible; they require there to be both kinetic and potential energy concerned; so, if either be absent something must happen to prevent solutions taking the oscillatory form. That something is the vanishing of the normal functions, excluding the $t\epsilon^{nt}$ terms, and making the solution in case of a double root take the form $a\epsilon^{nt}$, the same as if the root were not repeated.

Let n_1 and n_2 be a pair of n's, and write down the corresponding terms of the E_0 expansion. They are

$$\frac{\Sigma(E_0cE_1 - H_0\mu H_1)}{\Sigma(E_1cE_1 - H_1\mu H_1)}E_1\epsilon^{n_1t} + \frac{\Sigma(E_0cE_2 - H_0\mu H_2)}{\Sigma(E_2cE_2 - H_2\mu H_2)}E_2\epsilon^{n_2t}. \; . \; . \; (115)$$

Here there are no restrictions put upon c, k and μ; E_1, H_1, and E_2, H_2, are the normal functions corresponding to n_1 and n_2, and the $U_{12} = T_{12}$ formula has been employed to find A_1 and A_2, the coefficients of E_1 and E_2 (the fractions).

At first glance it might appear that if, by some change in the value of some electrical constant concerned, or generally, by a changed distribution of c, k, μ, the roots n_1 and n_2 are made to approach and finally reach equality, making E_1 and H_1 also approach to and finally be the same as E_2 and H_2, their coefficients A_1 and A_2 will also approach and ultimately be equal. But, in general, nothing could be further from the truth, and instead of equality, we shall have infinite inequality, on account of the denominators approaching zero from opposite sides, sending one A up to positive and the other down to negative infinity. For if $n_1 = n + h$, and $n_2 = n - h$, where h is very small, we shall have

$$E_1 = E + hE', \qquad H_1 = H + hH',$$
$$E_2 = E - hE', \qquad H_2 = H - hH',$$

if the accent denote differentiation to n, provided the functions E, H, and their differential coefficients do not vanish. These make

$$\Sigma(E_1cE_1 - H_1\mu H_1) = 2h\Sigma(EcE' - H\mu H').$$

This is the value of the denominator of A_1 in (115), and that of A_2 is the same taken negatively, thus showing the infinite divergence of the A's.

The two terms, when united, and h made to vanish, give rise to a solution of the form

$$C_1F\epsilon^{nt} + C_2Et\epsilon^{nt},$$

where C_1 and C_2 are new constants, E is the old E, and F is a new function derived from E. From this we see that when the repeated n makes the normal functions vanish, as when any one of c, k, μ is zero, the second term goes out altogether.

The double root solution in these cases of vanishing E and H is

$$\frac{\Sigma(E_0cE' - H_0\mu H')}{\Sigma(E'cE' - H'\mu H')}E'\epsilon^{nt}, \quad . \quad . \quad . \quad . \quad (116)$$

differing from the original form only in this, that instead of the normal functions E and H we take their differential coefficients with respect to n. This single term takes the place of the former two terms.

If the root n be triple, E' and H' will also vanish. Then take E'' and H'' instead; and similarly go on to further differentiations in case of further repetitions of n.

If $N = 0$ be the determinantal equation of the n's, the function $U - T$ of a normal system contains N', the differential coefficient of N with respect to n, as a factor. $N' = 0$, in addition to $N = 0$, is the condition that n is a double root. Similarly, the function $U - T$, not of E and H, but of E' and

Digitized by Google

H′, contains N″, the second differential coefficient of N, as a factor, and so on.

Before leaving this curious subject of the effect of equal rates of subsidence, we should notice that when the duplicity of an n, making the conjugate properties of unequal n's hold good for two of the same value, necessitates the simultaneous vanishing of the normal functions, it does so in virtue of the positivity of Q, U, T, as before mentioned. But should they be allowed to be negative, although, for example, in the case $c=0$, we still have $T=0$, $Q=0$, when an n is double, there is no longer any necessity for E and H to simultaneously vanish. Then we have the $t\epsilon^{nt}$ term, and the $t^2\epsilon^{nt}$ term if a triple root, and so on. The vanishing of T will then depend on its expression containing N, for the special value of n, as a factor. As our expressions for Q, U, and T are in the form of the sum of scalar products, we can only make any one of them negative by allowing that the force and the flux, in some parts of space at least, can make an obtuse angle with one another; that is, be opposed, which is a contradiction to common sense. In special applications, involving only a limited number of degrees of freedom, the positivity of U, T, and Q will require that certain functions of the electrical constants, usually determinants, cannot be negative for any values of the electric variables.

(To be continued.)

THE MANUFACTURE OF THE CRUTO INCANDESCENT LAMP.*

The well-known and frequently-described Cruto lamp has attracted attention at exhibitions at Munich, Vienna, Turin, and Paris. According to published measurements made, the energy absorbed in these lamps is 3·4 volt-amperes per standard candle. The process of making the carbons may be described:—(1) Formation of the carbon filament. (2) The fitting of the latter to the platinum. (3) Sealing into the globe. (4) Exhaustion of the lamp. (5) Testing the finished lamp. (6) Accessory fittings.

In the case of the Cruto lamp carbon, which is obtained by a deposition of carbon on platinum after the manner of Wollaston's process, the employment of furnaces and moulds is unnecessary, and the resistance of the filament can be easily regulated during the course of manufacture.

The apparatus used for the depositing is simply a long glass vessel filled with a gaseous hydro-carbon, in which is suspended a platinum wire maintained at a dull heat by means of a current of electricity. By contact with the heated wire the gas is decomposed, producing a deposit of carbon upon it. The layers of carbon so obtained now take part in the incandescence, producing a further decomposition, and thus rendering the process continuous.

The gas generally used for the operation is ethylene (C_2H_4), generated in large receivers from a mixture of one part of ethylenic alcohol and two of pure sulphuric acid. Before the gas is allowed to enter the gasometer it is washed several times with pure water, or water containing calcium chloride and sulphuric acid, in order to purify it from the different compounds formed simultaneously with itself, such as ether, carbon dioxide, sulphuric acid, &c. On leaving the gasometer the gas is further dried with calcium chloride and Nordhausen sulphuric acid.

The platinum wire itself is made by the Wollaston process. A metal wire is drawn out to a very small sectional area, and then coated with silver. The wire is then drawn still further till its whole diameter is $\frac{1}{40}$th of a millimetre, and that of the platinum alone $\frac{1}{100}$th of a millimetre.

In the Cruto lamp the length of wire depends on the type of lamp required. The wire is bent into the shape of a U, while its extremities are firmly held in clamps. The silver is dissolved with dilute nitric acid, and the wire suspended in the apparatus.

These different operations are conducted by women, who do their work well and accurately.

* From *Zeitschrift für Electrotechnik.*

All the carbon depositing vessels are connected in parallel with the terminals of a Gramme machine in series with a semicircular rheostat of 200 ohms, subdivided in portions of 10 ohms each, with an additional resistance of 30 ohms, composed of two groups of 5 ohms, five of 2, and ten of 1.

The resistance of the filament is so high that an electromotive force of 180 volts only gives a weak current. However, in order still further to reduce the current, a movable arm can be used as a shunt. The long glass vessels already mentioned are arranged in two rows on either side of the table, all connected by a central wire with the positive pole of the machine. The current passes from this wire through the rheostat, then through the glass vessels, and then through a switch back to the negative terminal. Shunt circuits are brought into use by two wires joining the negative pole of the dynamo with all the movable arms.

If we follow the change of resistance in the wire, and construct a curve representing its values at intervals of 10 ohms, we find that the resistance of the platinum wire at first decreases, and then rapidly reaches a value higher than that with which it started. An explanation suggested is that the platinum wire melts at a particular moment, and leaves the carbon alone, or that a *quasi* compound of platinum and carbon is formed. After this the resistance steadily falls, while the curve becomes more regular. In order to prevent interruption of the decomposition of the gas, the wire must be maintained at a high temperature. At the commencement of the operation a very small current is sufficient for this purpose. The rheostat, which admits of any necessary variation, allows the current from the dynamo to be reduced to the amount required. The resistances being so adjusted as to maintain the filament at a constant temperature, the strength of current passing through the wire is gradually increased as it grows in thickness. A simple contrivance, due to M. Thibaudeau, allows the resistance of the filament used to be gradually adjusted with sufficient accuracy, the operation being stopped when the necessary value has been obtained.

A special arrangement insures that the measurement is taken with the filament at a constant temperature. The standard resistance of the apparatus, equal to that of a sample filament in course of construction, is fixed, once for all, in a Wheatstone bridge. The operator has only to press a key to see whether the corresponding filament is finished or not—that is to say, whether its resistance has reached the necessary value.

At the commencement of their formation the passage of a current through such fine and flexible conductors puts them under the influence of the magnetic action of the earth. They must therefore be placed on a plane at right angles to the needle of an inclination compass in the magnetic meridian. The support of the apparatus is therefore made movable to admit of adjustment in any desired position. But besides this magnetic action there is the mutual repulsion of two parallel currents flowing in opposite directions, tending to separate the two halves of the loop. The horseshoe begins to bulge, and the wire will acquire a clumsy appearance if care is not taken, as soon as the filament begins to get solid, to reverse the direction of the current by a suitable switch. The wire then shows a tendency to take a spiral form, the two portions of the loop draw together, and the horseshoe form is obtained. The current is now restored to its original direction. If the change is made too suddenly the wire twists into the shape of an 8 with its upper half broken—thus, 8. The bending over of the upper part and the excessive strength of the current destroy the wire at the instant when the two loops come in contact with each other. With the aid of a magnet it is easy to move a filament in various ways, and this method is employed in practice to correct distortions which have occurred in the process of manufacture.

The action which takes place in the process of deposition of the carbon is, from a chemical point of view, somewhat difficult to explain. It can, however, be modified by the presence of gaseous compounds of alcohol or ether, in which case water also makes its appearance; care is therefore taken to remove these bodies by washing the gas. As regards the decomposition of the pure gas, there is nothing to go by except the works of Berthelot, who, however, has not published a

Digitized by Google

complete explanation of the reaction. It may, however, be observed that the apparatus used for the manufacture of the filament could be advantageously applied to the study of the decomposition of ethylene. If the deposit takes place gradually, and with uniformity, the result is a correspondingly compact whole. If, however, from one cause or another this fails to happen, the wire appears as though composed of a number of tubes one within the other. The filaments are then useless, as they either break or scale off at the first passage of the current. But such accidents rarely occur in practice. The production of the carbon filaments by electro-chemical deposition of carbon occupies on an average about two hours and a half.

When the carbon filaments are equal in length and resistance they are of the same thickness. This is claimed as a great advancement on other methods of manufacture in which these three values, length, sectional area, and resistance are not so easily regulated. The filament has to be fixed to the extremity of the platinum wires fused into the glass as contacts. These platinum wires are made tubular at their ends, and the filaments are fixed into the tubes so formed by a deposit of carbon. The filament, fixed in a holder of the shape of an inverted U, is held in position by clamps. On the same surface, but separately insulated, the two tubular ends of platinum are held by a second pair of clamps. Between the four clamps the deposit is formed.

This method may be safely preferred to all methods now in use, even to the copper depositing process, and that of mounting with porous carbon points.

This part of the process relating to blowing the bulb and inserting the carbon calls for no special mention, differing little from the method adopted with other lamps.

The most difficult operation in the manufacture of the incandescent lamp is the exhaustion of the air. This is effected by means of a Sprengel pump, the general arrangement of which is well known. The branch tube by which the exhaustion is conducted has an enlargement on its upper portion containing some active hygroscopic substance such as sulphuric acid or phosphoric anhydride. The lamp to be exhausted is attached to a tube sealed into this enlargement. The completion of the exhaustion is indicated by the dull, unmusical fall of the drops of mercury in the pump. The filament of the lamp to be exhausted is connected in series with a rheostat in the circuit of a dynamo; when the globe is sufficiently exhausted, a current, weak at first, is allowed to pass, causing a far more rapid evolution of the rarefied gases, the mercury often falling quite silently. The current is gradually brought up to the normal strength used in the ordinary work of the lamp, and cut off as soon as the mercury appears to carry no more bubbles down with it. The lamp is then sealed up, and is ready for testing.

The management of the Sprengel pump requires excessive care. The mercury, for instance, must be dry and free from impurities. It is also necessary to keep it always pure. For this purpose it is washed with sulphuric acid, and passed before entering the pump through an atmosphere dried with calcium chloride, and a second bath of sulphuric acid. The lamps are also dried before being attached to the pump by a current of perfectly dry air.

Testing the Finished Lamp.—The finished lamps are brought into the test room to have their candle-power and efficiency tested by the eye, careful precautions being observed which allow of these operations being conducted with speed and accuracy. The amount of current used in a standard lamp of the same illuminating power is noted down on the lamp under test, which is then replaced by another. The same is done with the electromotive force. This classification is carried out very rapidly, and requires on the part of the operator only practice in observation. When greater accuracy of measurement is desired, the Bunsen photometer is observed simultaneously by two persons on opposite sides, and instruments, such as voltmeters and ammeters are used. In this case the photometric observations are repeated with a photometer with two screens. In this way the difference in tint of the two light spots thus placed side by side may be more easily estimated. These two methods, which are easily carried out simultaneously, are thus made to check each other. Besides these electrical and photometric measurements, further observations are made to determine the life of the lamp under normal conditions of use. The lamps are connected to a dynamo machine, with a single rheostat for each lamp, and another for the total current. A special contrivance allows the energy consumed by each lamp to be frequently increased without interrupting the current. In this way the changes in the resistance of the filament can be easily followed, and compared with the illuminating power obtained. A numerical result is thus reached for the best working conditions for the lamp.

Mounting the Lamp.—The mounting of the Cruto lamp calls for no special mention. All known systems have their good and bad points, and the method here adopted is certainly one

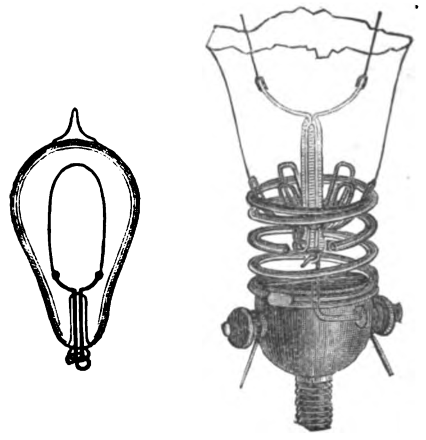

Fig. 1.

of the best (Fig. 1). The numerical constants of the different types of lamps are given below.

Type.	Candle-power.	E.M.F. in volts.	Current in amperes.
—	32	100	1·05
*A	20	100	·60
B	10	50	·60
C	16	50	1·05
D	8	25	1·05
E	50	50	2·30
*F	100	90	2·25

* These are double carbon lamps.

Small lamps of four to 20 volts are also manufactured for use with batteries, and are so efficient as to yield more than one candle per volt of electromotive force.

A Standard Cell.—M. Gaiffe remarked, as long ago as 1862, that the strength of the solution in chloride of silver batteries influenced their electromotive force, a stronger solution giving a smaller electromotive force. Upon this principle he has constructed a cell with a solution containing 5 per cent. of chloride of zinc, which gives an electromotive force of 1·02 B.A. volts, or 1·01 C.G.S. volts. It is necessary to employ pure materials, in order to keep the electromotive force of the standard cell constant. The temperature ought also to be kept constant during the time of observation, and to be the same degree in the various observations. Working with well-amalgamated zinc, pure melted chloride of silver, limpid solutions of pure chloride of zinc as neutral as possible and at the temperature of 18 deg. C., M. Gaiffe finds that the same solution always gives the same electromotive force. The liquor marked 107 by the densimetre appears to give the legal volt. In using the cell, resistances of at least 5,000 ohms should be used to prevent polarisation, as in the case of the ordinary chloride of silver element.

THE ROYAL SOCIETY AND PROF. HUGHES.

Not long after the discovery of the microphone, the Royal Society publicly recognised the value of Prof. Hughes's achievement by electing him a member of that distinguished body. More than seven years have elapsed since that discovery, and in the interval Prof. Hughes has added many claims to the gratitude of the scientific world by his unceasing industry in a field of electrical and magnetic research which, until he entered upon it, was extremely obscure, but which is now, thanks to him alone, becoming clearer and more intelligible every day. In recognition of these further obligations the Royal Society has this year conferred upon him the Royal Medal; and we are glad to notice that in another quarter Prof. Hughes's claims have been acknowledged in the highest manner practicable, the Society of Telegraph-Engineers and Electricians having elected him President for the ensuing year. Honours such as these, besides reflecting credit on those who bestow them, are always welcome even to the most modest of men; and in the present instance, if we may say so without impertinence, they are probably accepted with especial gratitude, seeing that they are virtually the only kind of reward the recipient has sought or obtained for his labours. In the very first number of *The Electrician*, where the preliminary experiments of the microphone were described in some detail, it was stated that "Prof. Hughes has declined to patent his inventions, but gives them, with whatever value they possess, to the world;" and we believe he has followed this magnanimous rule in respect to his subsequent inventions in the same field of discovery.

Considering the enormous sums of money that have been made, and will continue to be made, by the adaptation of the microphone to telephonic purposes, if any man may be pardoned for regretting a generous impulse that man is Prof. Hughes. We do not assert that but for his discovery the magneto telephone of Graham Bell would have been greatly restricted in its area of usefulness. It is possible that the ingenious contrivances of Edison, which came very near to Hughes's discovery both in time and character, might have ultimately given to the telephone the powers it needed as a practical appliance for public use; but, as a fact, Hughes's inventions were not only first but best, though not designed with the special object of serving the telephone; and to this day, amongst numberless competitors, nothing has yet supplanted the simple microphonic arrangement which Prof. Hughes originally erected with the help of the telephone. Without the telephone of Prof. Graham Bell microphonic phenomena never would have been studied; without the aid of the English microphone the American invention might have been impaired in usefulness or greatly delayed in its general application. Money has been made with the patented instrument, and vast fortunes reaped from both instruments in combination, but none, that we ever heard of, with the unpatented instrument alone.

It has long been a complaint against the telephone that it is not serviceable for long distances; but with characteristic forgetfulness the public have lost sight of the fact that the distances which the telephone now traverses, and which are now very considerable, we owe entirely to the microphone. Magnetic variations obtainable from the telephone, with or without battery power, are so slight that, though excellent as far as they go, they go a very little way. With the help of microphonic combinations this drawback has been considerably abated already, and if the problem of long distance telephony is to be solved it will probably be in the same direction. The sound actually given off by the best of telephonic combinations is but the faintest fraction of the originating sound. It is audible, and it seems as loud, or nearly as loud, at the end of the journey as at the beginning, because it is confined within a small space and brought close to the ear. That the diaphragm reproduces sounds with fidelity in such minute facsimile is, perhaps, the most wonderful feature of the string telephone, as well as of the magneto telephone; but the sound is not the same sound either in its nature or volume, any more than the magnified image of some remote star as revealed by the telescope is the star itself. The daily newspapers in discussing the prospects and shortcomings of the telephone are, of course, all abroad on these nice points; but not the newspapers alone. Some attempts that have been made to accomplish long distance telephony in quarters that ought to have known better betray almost equal ignorance of the true nature of the difficulties to be overcome.

Perhaps the most hopeful direction in which to look for a removal of these difficulties is one of which we were again reminded in Prof. Hughes's speech before the Royal Society last Monday week. "A loose electrical contact will repeat in sound any variation of current passing through it; consequently, we may speak to one loose contact and listen to a second, when every word spoken to the first will be clearly heard." This is only a repetition of what was stated seven years

Digitized by Google

ago, and verified many times since then. Telephones made of loose contacts for receiving as well as transmitting have been patented in considerable numbers; but generally, we believe, with the object of avoiding the patent rights of the magneto-telephone. If the same amount of ingenuity had been spent upon increasing the power of the transmitter and enlarging the mechanical effects on the receiver, telephony over longer distances than can at present be accomplished might have been practicable. But be this as it may, Prof. Hughes's microphone has already achieved a fame that will be immortal. His subsequent inventions arising out of it, the Induction Balance and Electric Sonometer, have a future before them hardly less important in the sphere of experimental and applied science; and the curious light which by their means already he himself has thrown upon magnetic phenomena promises to illuminate one of the darkest corners of natural physics. Talents such as those which invented the Type Printing Telegraph and discovered the Microphone are seldom combined in one person; and learned Societies may rejoice when so fitting an object can be found for the honours which are annually at their disposal.

CORRESPONDENCE.

THE INDIAN TELEGRAPH SERVICE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We beg to thank you most sincerely for the very able article in your issue of the 9th ult., in which you notice the grievances of the officers of the Indian Telegraph Department, and accord a body of hardly dealt with public servants your powerful support.

With regard to the third paragraph of the article, in which you specify two weak points in our memorandum, we would submit the following remarks:—

1. The memorandum, which was originally dated 1st April, 1885, was drawn up for private circulation amongst members of the department and their influential friends, and as there was no chance of them attaching the idea of "unseemly asperity" to any part of it, words here and there are doubtless not so carefully chosen as they would have been, had it been necessary to guard against the possibility of misconstruction. That it was thoroughly understood that no attack on the interests of "the men who create the block" was intended is proved by the fact that they have nearly all cordially joined the movement.

2. The subsequent more extensive circulation of the memorandum was an afterthought. We hoped to get it circulated before the close of the last Parliamentary Session, and, being pressed for time, we did not think it necessary to re-write it, for it never occurred to us that phrases perfectly intelligible to the original small circle of readers might be misconstrued by readers unacquainted with the fact that there is no antagonism whatever between the men appointed prior to 1868 and those more recently appointed.

3. We may be guilty of "special pleading," for we are pleading our own cause, and, such being the case, it is almost impossible we should not lay ourselves open in some respect to the charge, though we honestly believe we have exaggerated nothing.

4. The memorandum does not propose either compulsory retirements, or compulsory transfers, and we have good ground for believing that, if fairly generous terms are offered, there will be sufficient voluntary retirements to relieve the block in promotion.

5. We fully realise that to retire seniors only would be to shift the block, not to remove it; we therefore urge that inducements to retire be offered to all men of over 15 years' service in India, and we know that if reasonable inducements are held out the voluntary retirements will not be confined to seniors.

The suggestion to remove the block in promotion by increasing the number of appointments, is not likely to find acceptance with the Government of India, whose proposals for the reorganisation of the Departments provide for a decrease in the "superior" establishment (salaries Rs.250 to Rs.3,000 per mens), and a corresponding increase in the "upper subordinate" establishment (salaries Rs.250 to Rs.350 per mens).

This also is a change quite in accordance with the views of the executive officers of the Departments, who believe that from 25 to 30 of themselves may safely be retired without any need for filling the vacancies thus created, provided the number of "upper subordinates" be increased, and work be more equally distributed than it is at present.—Yours, &c.,

HONORARY SECRETARY (Indian) Telegraph
Engineers' Defence Committee.

Calcutta, 16th Nov., 1885.

HIGH-SPEED ENGINES AT THE INVENTORIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to a letter from a "Puzzled Student"—who seems to be very easily puzzled—the explanation he requires is as follows:—The machine described in detail in *The Engineer* of June 26th was one of two machines sent to Buckingham Palace, which, on test, gave 110 volts at 440 revs., whereas the machines doing the work at the Inventories, although of practically the same design, were of smaller dimensions, and were differently wound. They were designed to meet the Admiralty requirements of 80 volts at 400 revs., but, when tested at our works, they gave 80 volts at 370 revs., or 30 revs. below the specified speed. For the lighting of Old London, however, it was necessary to supply an E.M.F. of 120 volts at the terminals of the machines, and your "Student" will readily see for himself that the increased speed of 550 revs. was necessary to obtain these volts.

The mistake made by the writer in *The Engineer* is a very small one. He has simply given the dimensions of the Buckingham Palace machine twice over, instead of in the first instance describing the machine actually exhibited. No doubt the reason of this was that we supplied full and complete drawings as well as a photograph of the Buckingham Palace machine, whereas we were not able to supply detailed particulars of the machines exhibited. At any rate, we did not think such a slight error required correction. We quite agree with your correspondent that manufacturers of dynamos are proud of their slow-speeds, and probably we ourselves have gone as far in this direction as any one. Our letter, however, was not to enlarge on slow speed dynamos, but to call attention to the fact that thoroughly trustworthy, economical engines could be obtained to run at what we consider the high speed of 550 revs. per minute.—Yours, &c.,

R. E. CROMPTON AND CO.

Mansion House-buildings, London, E.C.,
December 1, 1885.

THE RECENT INCANDESCENT LAMP TESTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It was not our intention to take any notice of the published results of the Franklin Institute tests on incandescent lamps, as, considering the very strong comments that had been made on the subject in the various electrical papers, we thought it most unlikely that any one would be misled by them. We have, however, been advised that unscrupulous persons—more especially on the Continent—have been taking advantage of these tests to disparage our lamps. We shall therefore be glad if you will allow us the opportunity of emphatically denying that any reliance is to be placed in them, and of placing the following facts before your readers.

Digitized by Google

We were advised by our agent in America to have nothing to do with the tests, as they would not be reliable, the Swan, Maxim, and other makers of incandescent lamps having refused to allow their lamps to be entered. We therefore decided not to compete. Lamps, however, stated to be ours were entered without our knowledge or consent, half being actually supplied by the Edison Company, the chief competitors, and the rest being obtained from another electric lighting firm. Whilst being admittedly run at five volts above what they were labelled, giving out up to 40 per cent. or 50 per cent. above the proper candle-power, they were placed in competition with lamps evidently most carefully made and tested beforehand.

As an example of the way in which the electrical press have treated the tests, we may call attention to the *Electrical Review* of America, dated June 13th, in which are given verbatim reports of interviews with the president and secretary of the Institute, the latter stating that he refused to have anything to do with the incandescent lamp tests, because he did not believe in them. Another official of the Institute stated some three months ago that it was very doubtful if the tests could be seen by outsiders, as the tests themselves did not agree.

Whilst in many instances disagreeing with the methods adopted in the actual tests, we refrain from criticising them, as we are well aware of the many difficulties that have to be contended with. We merely add that we think that the Institute ought to have seen that we were properly protected and advised of what was going on.

We are glad to hear that there is some chance of complete tests being made in this country, when every precaution will be taken to ensure their being properly made.—Yours, &c.,

WOODHOUSE AND RAWSON.

ELECTRIC HAULAGE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed in your issue of December 4th a letter, signed "H. S.," which is conspicuous for the spirit of carping criticism shown throughout. It is a well-known fact that immediately an inventor steps out of the beaten track to accomplish something which has proved a failure in other hands, there are plenty of so-called scientists ready with a perfect avalanche of figures to hurl upon his invention, and effect its total demolition. Such logicians of the schools, however, prove, day by day, that it is easier to demolish than to erect, and if by any chance they ever attempt a practical test of their own figures, they find to their cost how fallacious are their arguments. "H. S." measures the friction in the gearing of my locomotive by some magnifying standard of his own invention, without going into details. I will simply give an instance in our actual experience to illustrate the errror he has permitted himself to publish. In the presence of Mr. Adamson, general manager of the North Metropolitan Tramway Company, and several other gentlemen, I placed a locomotive upon the line, with a small motor connected according to my patents; the weight of the machinery and accumulators was 4 tons 17 cwt. I attached three empty cars to the locomotive, and with 1·5 mechanical horse-power upon my *motor spindle* I drew these three cars, weighing 7½ tons (in all about 12 tons), at a speed of about 2½ miles. If, then, according to the statement of "H. S.," I lose 1·3 horse-power in friction, there only remained 0·2 horse-power for the propulsion of 12 tons at a speed of 220ft. per minute. If I could, indeed, accomplish such a feat, I should be more deserving of the attainments of Hercules than of Archimedes I wish to state, finally, that I cannot in the future reply to carping letters like that of "H. S.," as I consider my time to be better occupied in proving by practical demonstration the success of my principle than in wandering over a dreary waste of useless figures at the will of every person who wishes to air his knowledge at the expense of the space of a scientific journal.

Should "H. S." or any of his collaborateurs desire to go into the details of my locomotive I would advise them to pay it a visit at the North Metropolitan Tramway Company's depôt at Stratford, where I shall be happy to show them practical work if they will apply previously to myself or the secretary of the company.—Yours, &c., C. P. ELIESON.

THE SOCIETY OF TELEGRAPH-ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your remarks as to the proceedings of the Society of Telegraph (?) Engineers and Electricians were very proper. I received my ballot paper a few days ago, and thoroughly disgusted with it I was. Amongst the nominees for places of honour I could not observe—except in one or two instances, where the "big ones" are again patted on the back—the single name of a gentleman practically connected with telegraphy proper; nor could I see the name of one man from the Provinces. London men divide all the honours amongst themselves, and we country supporters will soon have to ask ourselves whether the thing is worth the money. "The Society of Electric Light Engineers and Electricians" would be a more correct name than the present one, seeing that of all our highly-respected railway telegraph engineers and also telephone engineers not one of them is considered good enough to be placed on the Council, forsooth. I believe Mr. Spagnoletti was the first railway man to be elected President —a burning shame—and if he had not been a Londoner, goodness only knows when he would have received an invitation. Telegraph matters are now considered by the Council as of secondary importance, and telegraph men will soon begin to drop off the subscription list.—I enclose my card, and remain, yours, &c., BATTERY BOX.

RECKENZAUN'S ELECTRIC LAUNCHES.

When, last summer, the Duke of Bedford had a cruise in the electric launch "Australia" in company with Lord Sudeley and the designer of the yacht, Mr. Reckenzaun, his Grace recognised the usefulness of such a boat on board a steam yacht, and ordered a similar one, which he intended should be used both as a launch and an auxiliary for lighting his yacht by means of the accumulators.

This launch was tried last week at Westminster. It is 3ft. longer than the "Australia," but the internal arrangements are similar. Twenty-nine E. P. S. cells are placed in the centre under a board, which also forms a seat. The battery actuates a Reckenzaun motor, to which is coupled the shaft and propeller. The launch can run at the rate of six knots per hour, each charge supplying power at this rate of four hours and a half.

When suspended in the davits the accumulators in the boat can be used for lighting the yacht, and the charging of the cells is obtained from the dynamo that lights the yacht "Northumbria."

The charging of the cells is effected by the same dynamo that lights the ship, so that no special apparatus is necessary. The boat has been fitted throughout by the Electrical Power Storage Company, and contains several improvements in the manipulation and reversing gear on those previously made by this company.

There were present at the trial (which was most satisfactory) Lord Sudeley, Mr. White (Director of Naval Construction), and Major-General Webber, C.B., and the Storage Company was represented by Mr. J. Irving Courtenay, Mr. Bernard Drake, and Mr. J. W. Gorham.

We are informed that Mr. Reckenzaun has at this moment several designs in progress which will embody further substantial improvements in the electric launch. One of these designs is being executed to the order of the Italian Government, and is adapted for naval purposes; another is being executed to the order of an Indian prince. The latter is a pleasure boat, luxuriantly arranged with saloon and magnificent furniture. It is splendidly illuminated by means of incandescent lamps, and the ventilating fans are actuated also by electrical apparatus.

LITERATURE.

Lectures on Heat, Sound, and Light. An Elementary Text Book for Students. By Richard Wormell, D.Sc., M.A. [Thomas Murby, 3, Ludgate-circus-buildings, E.C.]

Chemical Student's Manual, for the Lecture Room and the Laboratory. Embracing Non-Metals, the Analysis of Simple Salts, &c. By Herbert L. Buckeridge, F.C.S. [Thomas Murby, 3, Ludgate-circus-buildings, E.C.]

Dr. Wormell has long been recognised as an earnest teacher. He possesses a wide knowledge of the subjects upon which he writes, and, what is quite as important, great experience in teaching. We have read through many of the lectures or lessons in this book, and find the subject matter correct, well put, the illustrations apt, and to the point. The idea is to provide a progressive course for school work, extending over a period of about a year and a half or two years. At the end of each section a series of notes upon laboratory practice is given, and at the end a number of examination questions. If we ventured upon a suggestion, it would be to eliminate from a new edition all such paragraphs as "How to Make a Thermometer." No class of students at so early a stage in their scientific training could be expected to follow the directions given. Probably, Dr. Wormell in these paragraphs has not followed his own experience, but has given way to the foolish cry that students should make most of their own tools, and that by so doing the cost of teaching science would be lessened. With this exception we have nothing but praise for Dr. Wormell's work.

The second book mentioned above is of a different character altogether, and partakes more of the student's note book than of his text book. No doubt such books are of great service when used properly, but condensation does not always lead to information. As a *memoria technica* to a good course of lectures or exhaustive text books this work seems well adapted. The facts are well arranged and clearly stated.

SUBMARINE CABLES IN WAR.

In January, 1850, the French Government conceded to an English company the right to establish telegraph communication across the Channel by a submarine cable. Not till August, 1857, however, was the first attempt made to bridge the Atlantic, when the old "Agamemnon," since replaced, and the United States frigate "Niagara" started from Valentia Island with a cable which broke at the three hundredth mile, thus bringing the venture to an untimely end. Since that time, all the difficulties of cable manufacture have been overcome. Cables can be laid with certainty and rapidity, so that the world has been gradually girdled with the slender cords which annihilate space, and we in London to-day are able to speak to Australia as surely and in less time than was needed 100 years ago to communicate with Oxford. From Valentia Island, Falmouth, and Brest a belt of ten cables traverses the Atlantic, and strikes the opposite shores at St. John's, Newfoundland, and at Sydney, Cape Canso, and Torbay, Nova Scotia. Thence land lines cross North America to San Francisco, and trend north through British Columbia to remote Alaska. From Falmouth again, through Lisbon, Madeira, and St. Vincent, two cables slant down across the Atlantic to Pernambuco, in Brazil, whence one coast line leads northwards to Para, at the southern mouth of the Amazon, while another, bending south to the mouth of the Parana, connects with the land line crossing the Argentine Republic and Chili to Valparaiso, thence communicating with another coasting cable girdling the eastern shores of the Pacific through Callao and Panama to Tehuantepec. From Panama, a line crosses the isthmus to Colon and links with a cable which, passing north under the Caribbean Sea, unites at Kingston, Jamaica, with another line starting from Florida, and, running along the great chain of the West India Islands, ends at Georgetown, in British Guiana. Still another Atlantic cable leaves Lisbon and passes through the Canaries to Senegal. Eastwards from England, cables run down the Mediterranean from Gibraltar, Marseilles, Otranto, and Trieste to Alexandria, where one branch leads north east through Cyprus to Latakieh, and, connecting with overhead wires stretching down the valley of the Euphrates to the Persian Gulf, links with a cable landing ultimately at Kurrachee. Three cables pass down the Red Sea, of which one branches off from Aden through Zanzibar to Port Natal, thence communicating overland with the Cape; while the others continue their course to Bombay and couple up with land lines crossing Hindostan to Madras. From Madras, a cable leads south-east through Penang, Singapore, and the eastern angle of Java to Port Darwin, linking to the long land line which bestrides Australia to Port Augusta, and thence communicates, *vià* Melbourne, with Tasmania and, *vià* Sydney, with New Zealand. Branching off from this main line at Singapore, a cable leads to Saigon, and, passing up the China Sea to Hong Kong, skirts the coast to Shanghai, and crosses the Yellow Sea to Nagasaki, ending at Vladivostock, where it joins the great Russian land line, which completes the circuit back to Europe. Quite recently an independent line has been laid, coupling Hong Kong with Port Hamilton, near the southern point of the Corean Peninsula.

This vast system, which places London within a few hours of Alaska, the Cape of Good Hope, New Zealand, and the Okhotsk Sea, has grown up for the most part on no principles except those dictated by trade requirements, is under no sort of international protection in war time, has no defined *status* in international law. Strategically speaking, it is, from an English point of view, manifestly defective. The only communication with the important naval fortress of Hong Kong passes through Saigon, a French station. All communication with Gibraltar and Malta traverses French, Spanish, or Portuguese territory. The important stations of Sierra Leone and St. Helena are at present inaccessible, while Mauritius lies isolated in the Indian Ocean and Bermuda in the Atlantic. Along the Suez Canal route to India, cable communication is very complete, but would be somewhat precarious in war time. The long sea route, however, the great alternative on which alone England can securely reckon, is without any communication with the exception of the unreliable line *vià* Zanzibar to the Cape. The position of all the cable lines of the world is known with tolerable accuracy, and their destructibility varies practically with the depth of sea-bottom. It would probably be a long task to grapple for the North American lines in mid-ocean, considering that five weeks have been needed to find the line between Colon and Jamaica; but the shallow sea and the coasting lines would not be difficult to discover and to cut, while shore ends must, in many instances, be specially vulnerable. Thus, in a large number of cases, the possibility of preserving telegraph communication during war must depend mainly on naval activity. The Russians were reported to have made arrangement for cutting cables had war broken out this year, and it is evident that, if vessels specially equipped for the purpose can succeed in keeping the sea for any length of time, the amount of injury which could be effected would be very serious. Given speed, coal-endurance, and daring, this new method of damaging an enemy offers chances which are too well realised to be thrown away. The advantage of uninterrupted telegraph communication between a Minister of War and the headquarters of an army in the field is highly questionable, and a great general would probably find means to cut his cable upon occasion; but the strategic importance to England of maintaining telegraphic touch of her foreign stations can hardly be overrated. War ships are now dependent on the coaling stations, which give them the means of movement, and communication with these stations confers the power of naval concentration, and renders naval strategy possible in the higher sense, while it secures the timely warning which may mean safety. England has important stations which might be attacked in force long before the news of a declaration of war could reach them.

Broadly speaking, the danger to cables would be greatest at the outset of hostilities. As soon as England had definitely embarked on a great war, and had more time to develop her naval strength, and make her supremacy felt on the high seas, that danger would sensibly diminish. Cables can be repaired

Digitized by Google

almost as easily as cut, since the main difficulty in either case is to find them. New lines can be rapidly laid. Ordinary foresight would, therefore, indicate that certain stations should always contain a large reserve of cable ready for emergencies, and that properly equipped laying and repairing ships should be available. The adoption of such an obvious measure of precaution might be taken for granted were it not that other vitally important measures have been openly neglected; while for years we have rested content with a scarecrow defence for the coaling stations on which the Empire may any day depend.

It is doubtful to-day if half the members of the House of Commons could give their mere names, so superior are the fascinations of parochial matters to those of high Imperial affairs. Complex and conflicting interests have grown up around the giant cable system of the world, some of which are worth noticing. Assuming that France, during a war with England, were to cut the Mediterranean or Red Sea cables, she would deprive herself of all possible telegraphic touch with her Indo-Chinese possessions; since messages even if sent across Asiatic Russia to Vladivostock would be liable to interception at Hong Kong before reaching Saigon.

Moreover, to cut these cables would not deprive England of communication *viâ* Constantinople and the Persian land lines with India, and thence with Singapore, Australia, and New Zealand. England would have lost touch of the Cape, but could still speak to Aden *viâ* Bombay. On the other hand, since France could in no case feel assured of communication with Saigon and Tonquin—messages for either having to pass through Hong Kong or Singapore—the supposed measure might not only recommend itself, but might perhaps be supplemented by an effort to cut the Persian Gulf line to Kurrachee, the Aden-Bombay, the Madras-Penang, and the Rangoon-Penang lines, the total effect of which would be to telegraphically isolate England from India and India from Penang and Singapore, with the incidental result of seriously interfering with Dutch interests in Java, Spanish interests in the Phillippines, and possibly German interests at Zanzibar.

Supposing, however, that it was open to England to communicate *viâ* Russia and Vladivostock, a further cable cutting in the Yellow Sea or at Foochow and Amoy would be needed to isolate Hong Kong. The North American cables might remain intact, since they deeply affect American interests, while they are relatively less vulnerable on account of their multiplicity and great depth. Again, to cut the West Indian cable would be to interrupt communication with the French islands; but, since all messages pass through Jamaica, France might elect to cut the line between Kingston and Santiago, Cuba, ignoring the interests of the owners of islands to the westwards, but would have further to cut the Colon-Kingston line to isolate Jamaica. England, on her part, might attempt to cut the Brest cables, thus concentrating all communication with North America at Falmouth and Valentia; while she would probably cut the Senegal line between the Canaries and St. Louis.

The two cables from Marseilles to Algiers and from Marseilles to Bona might similarly be threatened by England, but the military advantages of cutting an enemy's communications diminish with their length, and the operation would not be particularly valuable.

Russia could hope for little from cables in a war with England, and all her own communications being interior land lines, she might elect to cut cables freely with the certainty of injuring English interests. While, however, she might seek to isolate Hong Kong and the Australian colonies, she could not interfere with the lines west of Singapore without touching French interests in Cochin-China and Tonquin, while eventually German interests may come to be involved in the cable to Zanzibar.

Thus, putting the North American lines out of consideration for the reasons above stated, it might be anticipated that Russia would seek to effect interruption north of Saigon, between Java and Port Darwin, and between Mozambique and Port Natal, with a view to isolate Hong Kong, the Australian colonies and New Zealand, and the Cape respectively. Mediterranean communications would, perhaps, not be threatened, and even if an interruption of the Persian land lines could be arranged, touch with India would probably be maintained.

Spain might conceivably seek to sever England's touch with Gibraltar, Italy to isolate Malta, England retaliating by cutting the Otranta line to Alexandria; but in this case many other interests would be affected and considerable inconvenience would be inflicted on neutrals without any great military advantage being gained by either side.

Combinations of Powers might have been assumed, but enough has been said to show how involved are the interests concerned and how conflicting the advantages to be reaped by cable-cutting. This alone will probably prove some safeguard to cables, and will at least serve to prevent mere random destruction. On the other hand, it is evident that of all Powers England has most to lose by the interruption of telegraph communication, while by retaliation she has little to gain. Thus far it has been assumed that the cutting of cables will play an important part in war, and that, as a weapon against England, it may be employed in spite of the commercial and other injury entailed upon neutrals. The whole question of cable-cutting is, however, one of which we as yet have no experience, and while it may be safely assumed that the rights, real and asserted, of weak neutrals will receive scant recognition, cases may occur in which the international aspects of cables cannot be lightly put aside.

International law is a vague term requiring much qualification. Great Powers agree formally that certain conditions shall be observed by them in war, or, by long observance, certain unformulated conditions win the sanctity of custom. This practically means merely that neither of two belligerents will go so far in contravention of this so-called law as to bring a powerful neutral into the field, and that neither is likely to commit any act which would bring upon it such a measure of moral opprobrium as might count as an adverse factor in its subsequent dealings with other nations. Weak Powers, unprovided with a strong backer, and semi-civilised Powers have reaped little benefit during war from international law in the past, and are unlikely to be able to calculate with certainty on its provisions in future. *Force majeure* can be advanced in justification of most questionable acts. When, in 1807, England suddenly seized the Danish fleet the act was probably indefensible under international law, while certain of the recent French proceedings at Foochow would tax the ingenuity of an advocate. While, however, international law has attempted to formulate regulations more or less definite with respect to such matters as contraband of war, submarine cables—either because their existence is too recent or because the questions relating to them are too complex and delicate—have not been brought within the scope of any understanding, formal or otherwise. It is true that the protection which an international agreement would promise could hardly be relied upon with any degree of certainty. Anchors might innocently foul important cables, and in weighing them it is only natural that the cables might be broken, just as no neutralisation of the Suez Canal will ever prevent vessels from accidentally sinking across it at critical periods. The grave inconvenience to neutrals which cable-cutting on a large scale would entail might, however, at least have led to an attempt to arrive at some sort of mutual understanding. It is worth while to consider a few of the questions which may any day present themselves. Despatches conveyed to a neutral by a belligerent are, of course, contraband of war. Are telegraph messages contraband, and may such messages, ocean borne, pass through a neutral station? Supposing France and Russia to be at war, can the Russians claim that no messages shall be sent over a British owned cable to Saigon? It is clear that such messages might possess military importance, while to stop them would practically mean that no telegraph messages could pass from Singapore to Saigon.

Even then sham messages, ostensibly for Hong Kong, might be read off at Saigon and might tell all that was needed. Have the Russians the right to cut the cable between Singapore and Hong Kong? This would compel all messages from England

Digitized by Google

for Hong Kong to pass through Vladivostock, an arrangement for which England might not greatly care. England and France are at war. Despatches for Halifax and Jamica are contraband. Has France the right—assuming that she has the power—to cut the Atlantic cables? To do so would be an almost intolerable nuisance to the United States, and would paralyse the business of New York. Again, how far does the ownership of cable lines affect the right to cut them, and could an American-owned line claim an immunity in this case which a British cable did not possess? France and the United States are the belligerents—are the British-owned cables liable to be cut on account of the value they would unquestionably possess for the United States? It might be argued that in mid-ocean they were the property of a neutral, but that within the territorial three miles of the American coast they were as destructible as a British-owned land line on belligerent soil. The above are only specimens of the class of questions which it is more easy to propound than to answer. Such questions may any day arise in the conflict of interests involved in cables in the capacity of transmitters of information of direct and indirect military importance, and in their civil capacity as international channels of communication by which the whole machinery of the vast commercial system of the world is moved.

Only last year the protection of cables in peace time formed the subject of an international conference. A series of measures were agreed upon and now form a part of international law under which wilful or culpable damage to a cable is punishable in Consular Courts. It is remarkable that not only was no attempt made to exchange views on the far more important question of the position which cables are to occupy in time of war, but a clause was adopted which seems capable of being construed into an invitation to cut cables ruthlessly.

By Article XV. it is provided that "the stipulations of the present Convention do not in any way restrict the freedom of action of belligerents." The Belgian representatives alone appear to have grasped the absurdity of this clause, and have placed on record their view that Article XV. is "absolument inutile aux yeux du Gouvernement Belge." Of all powers England is most interested in securing the sanctity of cables. Having little to gain by cutting them, she has much to lose as a neutral and as a belligerent by having them cut by other people. Guileless of any special qualification for dealing with such a question, and, as usual in such cases, unprovided with naval or military advisers, the British representative adopted, if he did not frame, a clause which will at least serve to render future negotiations more difficult. The clause is "absolutely useless," as the Belgians point out; this much will be generally conceded. The fact remains that the British Government, or its representative, was unable to see that anything which makes for the education of international opinion as to the neutralisation of cables makes for the interests of England, and was anxious to claim for her a freedom of action which, in default of all existing restrictions, no Power requires, and which she in particular does not really want. Of the 25 Governments represented at Paris some at least would probably have welcomed any proposal which tended towards the preservation of cable communications in war. If cable-cutting came into fashion and were elevated, or reduced, to a science, the position of neutral Powers would be lamentable, and it is even conceivable that the first military Power of the age would have been found willing to further the cause of civilisation by any measure directed towards the neutralisation of cables. It is useless to blind ourselves to possibilities we may have to face, and a cool consideration of these possibilities can do no harm. England being neutral, the seizure of a British ship by a belligerent would, under certain circumstances, constitute an act of war. The actual injury inflicted would be the merest trifle in comparison with that entailed by the cutting of certain cables. Is it permissible under any circumstances for a belligerent to cut those cables; or is England prepared to make the cutting of them a *casus belli* and to proclaim her intention in advance? On this point it is as well that we should make up our minds.—*The Times.*

ELECTRIC LIGHT LICENSE.

The following is a verbatim copy of one of the licenses issued by the Board of Trade, which can thus be used as a reference in the future by all interested in the subject:—

DALTON-IN-FURNESS ELECTRIC LIGHTING.

License authorising the Local Board for the District of Dalton-in-Furness, in the County of Lancaster, to erect and maintain Electric Lines and Works, and to supply Electricity, within the District of the said Local Board.

Preliminary.

1. This License may be cited as "The Dalton in-Furness Electric Lighting License, 1885."

2. This License is to be read and construed subject in all respects to the provisions of the Electric Lighting Act, 1882, and of any other Acts or parts of Acts incorporated therewith, which said Act and Acts and parts of Acts are in this License collectively referred to as "the principal Act;" and the several words, terms, and expressions to which by the Electric Lighting Act, 1882, meanings are assinged shall have in this License the same respective meanings, provided that in this License—

The expression "main" shall mean any continuous metallic conductor which may be laid down by the Undertakers in any street or public place, and through which electricity may be supplied or intended to be supplied by the Undertakers for the purposes of general supply:

The expression "distributing main" shall mean the portion of any main which is used for the purpose of giving origin to any service line for the purposes of general supply.

The expression "service line" shall mean any continuous metallic conductor used or intended to be used by the Undertakers for the supply of electricity to any particular consumer, either from any main or directly from the premises of the Undertakers.

The expression "general supply" shall mean the supply of electricity to ordinary consumers, and, unless otherwise specially approved of by the Board of Trade either generally or in respect of individual cases, to the public lamps, but shall not include the supply of electricity to any one or more particular consumers under special agreement.

The expression "the area of supply" shall mean the area within which the Undertakers are for the time being authorised to supply electricity under the provisions of this License:

The expression "The District" shall mean the Local Government District of Dalton-in-Furness as the same is constituted at the date of the commencement of this License:

The expression "The Local Board" shall mean the Local Board for the District:

The expressions "Schedule A." and "Schedule B." shall mean the Schedules A. and B. to this License annexed respectively.

3. This License shall come into force and have effect upon the first day of December, 1885, which date is in this License referred to as "the commencement of this License," and shall continue in force for a period of seven years from the commencement thereof, which period is in this License referred to as "the term of this License."

Description of the Undertakers.

4. The Undertakers for the purposes of this License shall be the Local Board: Provided that if the Local Board transfer all the powers, duties, and liabilities by this License conferred or imposed on them with reference to the supply of electricity in the district or any part thereof to any other body or person under the provisions of this License, such body or person shall be the Undertakers for the purposes of this License in respect of such area, as from the date of such transfer.

Area and Mode of Supply.

5. Subject to the provisions of this License and of the principal Act, the Undertakers may supply electricity within the district for all public and private purposes as defined by the said Act, provided that such electricity shall be supplied only by means of some system which may have been approved of by the Board of Trade either for general or special use, and subject to such regulations and conditions for securing the safety of the public, and for ensuring a proper and sufficient supply of electricity as the Board of Trade may from time to time impose, and that under no such system shall the Undertakers permit any part of any circuit to be connected with earth, except as so far as may be necessary for carrying out the provisions of any such regulations or conditions as aforesaid unless such connection is hereafter approved of by the Board of Trade, with the concurrence of the Postmaster-General.

Lands.

6. Subject to the provisions of this License and the principal Act, the Undertakers may from time to time, by agreement, purchase or take on lease any lands for the purposes of this License, and may use such lands, and any other lands which may for the time being belong to or be vested in or leased by them and may not be dedicated to the public as a park or recreation ground or be appropriated as a cemetery for the purposes aforesaid, and may from time to time dispose of any lands acquired by them under the provisions of this section which may not for the time be required for the purposes of this License: Provided that the amount of land so used by them shall not at any one time exceed in the whole five acres, except with the consent of the Board of Trade.

Digitized by Google

Works.

7. Subject to the provisions of this License and the principal Act, the Undertakers may from time to time exercise all or any of the powers conferred on them by this License and the principal Act, and may break up or otherwise interfere with so much of the railway and tramways specified in Schedule B. to this License as may for the time being be included within the area of supply, so far as the same may be or be upon any land dedicated to public use, and they may from time to time construct distributing boxes in any street for the purpose of supplying electricity.

Every such distributing box shall be for the exclusive use of the Undertakers and under their sole control, except so far as the Board of Trade may otherwise order, and shall be used by the Undertakers only for the purpose of leading off service lines and other distributing conductors, or for examining, testing, regulating, measuring, directing, or controlling the supply of electricity, or for examining or testing the condition of the mains or other portions of the electric lines or works, or for other like purposes connected with the undertaking, and the Undertakers may place therein meters, switches, and any other suitable and proper apparatus for any of the above purposes, and may maintain and use the same.

8. Where the exercise of any of the powers of the Undertakers in relation to the execution of any works (including the construction of distributing boxes) will involve the placing of any works in, over, along, or across any street or public bridge, the following provisions shall have effect:—

(*a.*) One month before commencing the execution of such works (not being repairs, renewals, or amendments of existing works of which the character and position are not altered), the Undertakers shall serve a notice upon the Postmaster-General, describing the proposed works, together with a plan of the works showing the mode and position in which such works are intended to be executed and placed, and shall, upon being required to do so by the Postmaster-General, from time to time give him any such further information in relation thereto as he may desire.

(*b.*) The Postmaster-General may in his discretion approve of any such works or plan, with or without any amendment or alteration, or disapprove of the same, and may give notice of such approval or disapproval to the Undertakers.

(*c.*) Where the Postmaster-General disapproves of any such works or plan the Undertakers may appeal to the Board of Trade against such disapproval, and the Board of Trade may inquire into the matter, and may allow or disallow such appeal, and approve of any such works or plan, with or without any amendment or alteration, or disapprove of the same:

(*d.*) If the Postmaster-General fail to give any such notice of approval or disapproval to the Undertakers within three weeks after the service of the notice upon him, he shall be deemed to have approved of such works or plan.

(*e.*) Notwithstanding anything in this License, or the principal Act, the Undertakers shall not be entitled to execute any such works as above specified, except so far as the same may be of a description and in accordance with a plan which has been approved of or is to be deemed to have been approved of by the Postmaster-General, or by the Board of Trade as above mentioned under this License; but where any such works and such plan are so approved of or to be deemed to be approved of, the Undertakers may cause such works to be executed in accordance with such plan, subject in all respects to the provisions of this License and of the principal Act.

(*f.*) If the Undertakers make default in complying with any of the requirements or restrictions of this section they shall (in addition to any other compensation which they may be liable to make under the provisions of this License or the principal Act) make full compensation to the Postmaster-General for any loss or damage which he may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding ten pounds for every such default, and in case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such default continues; provided that the Undertakers shall not be subject to any such penalties as aforesaid if the Court having cognisance of the case are of opinion that the case was one of emergency, and that the Undertakers complied with the requirements of this section so far as was reasonable under the circumstances.

9. Where the exercise of the powers of the Undertakers in relation to the execution of any works will involve the placing of any works in, over, along, or across any street or part of a street, not repairable by the local authority, or any railway, tramway, or canal, the following provisions shall have effect unless otherwise agreed between the parties interested:—

(*a.*) One month before commencing the execution of any such works (not being the repairs, renewals or amendments of existing works, of which the character and position are not altered), the Undertakers shall, in addition to any other notices which they may be required to give under this License or the principal Act, serve a notice upon the body or person liable to repair such street or part of a street, or the body or person for the time being entitled to work such railway or tramway, or the owners of such canal, as the case may be (in this section referred to as "the owners"), describing the proposed works, and stating the amount of compensation proposed to be made in respect thereof, and the manner in which such compensation is proposed to be paid or secured, together with a plan of the works showing the mode and position in which such works are intended to be executed and placed, and shall, upon being required to do so by any such owners as aforesaid, from time to time give them any such further information in relation thereto as they may desire.

(*b.*) Every such notice shall contain a reference to this section, and direct the attention of the owners to whom it is given to the provisions thereof.

(*c.*) Within three weeks after the service of any such notice and plan upon any owners, such owners may, if they think fit, serve a requisition upon the Undertakers requiring that any question in relation to such works and any other question arising on any such notice or plan as aforesaid shall be settled by arbitration; and thereupon such question shall be settled by arbitration accordingly.

(*d.*) In settling any question under this section an arbitrator shall have regard to any duties or obligations which the owners may be under in respect of such street or part of a street, railway, tramway, or canal, and may, if he thinks fit, require the Undertakers to execute any temporary or other works so as to avoid interference with any traffic so far as may be possible.

(*e.*) Where no such requisition as in this section mentioned is served upon the Undertakers, or where, after any such requisition has been served upon them, any question required to be settled by arbitration has been so settled, the Undertakers, upon paying or securing any compensation which they may be required to pay or secure in the manner proposed by them or settled by arbitration as aforesaid, may cause the works specified in such notice and plan as aforesaid to be executed, and may from time to time repair, renew, and amend the same (provided that their character and position are not altered), but subject in all respects to the provisions of this License and the principal Act, and only in accordance with the notice and plan so served by them as aforesaid or such modifications thereof respectively as may have been settled by arbitration as hereinbefore mentioned, or as may be agreed upon between the parties.

(*f.*) If the Undertakers make default in complying with any of the requirements or restrictions of this section they shall (in addition to any other compensation which they may be liable to make under the provisions of this License or the principal Act) make full compensation to the owners affected thereby for any loss or damage which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding ten pounds for every such default, and in case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such default continues; provided that the Undertakers shall not be subject to any such penalties as aforesaid if the Court having cognizance of the case are of opinion that the case was one of emergency, and that the Undertakers complied with the requirements of this section so far as was reasonable under the circumstances.

10. Any body or person for the time being liable to repair any street or part of a street or entitled to work any railway or tramway which the Undertakers may be empowered to break up for the purposes of this License, if they think fit, may from time to time serve a notice upon the Undertakers stating that they desire to exercise or discharge all or any part of any of the powers or duties of the Undertakers as therein specified in relation to the breaking up, filling in, reinstating, or making good any such street or part of a street, railway or tramway (as the case may be), and may from time to time amend or revoke any such notice by another notice similarly served.

Where any such body or person as aforesaid (in this section referred to as "the givers of the notice") have given notice that they desire to exercise or discharge any such specified powers or duties of the Undertakers, then so long as such notice remains in force the following provisions shall have effect unless otherwise agreed between the parties interested:—

(*a.*) The Undertakers shall not be entitled to proceed themselves to exercise or discharge any such specified powers or duties as aforesaid, except where they shall have required the givers of the notice to exercise or discharge such powers or duties, and the givers of the notice have refused or neglected to comply with such requisition, as hereinafter provided, or in case of emergency.

(*b.*) In addition to any other notices which they may be required to give under the provisions of this License or the principal Act, the Undertakers shall, not more than forty-eight hours and not less than twenty-four hours before the exercise or discharge of any powers or duties so specified as aforesaid is required to be commenced, serve a requisition upon the givers of the notice stating the time when such exercise or discharge is required to be commenced and the manner in which any such powers or duties are required to be exercised or discharged.

(*c.*) Upon receipt of any such requisition as last aforesaid, the givers of the notice may proceed to exercise or discharge any such powers or duties as required by the Undertakers, subject to the like restrictions and conditions as the Undertakers would themselves be subject to in such exercise or discharge so far as the same may be applicable.

(*d.*) If the givers of the notice decline, or for twenty-four hours after the time when any such exercise or discharge of any powers or duties is by any requisition required to be commenced neglect, to comply with such requisition, the Undertakers may themselves proceed to exercise or discharge the powers or duties therein specified in like manner as they might have done if such notice as aforesaid had not been given to them by the givers of the notice.

(*e.*) In any case of emergency the Undertakers may themselves proceed to at once exercise or discharge so much of any such specified powers or duties as aforesaid as may be necessary for the actual remedying of any defect from which the emergency arises without serving any requisition on the givers of the notice.

(*f.*) If the Undertakers exercise or discharge any such specified powers or duties as aforesaid otherwise than in accordance with the provisions of this section, they shall be liable to a penalty not exceeding ten pounds for every such offence, and in the case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such offence continues.

(*g.*) All expenses properly incurred by the givers of the notice in complying with any requisition of the Undertakers under this section shall be repaid to them by the Undertakers.

Digitized by Google

(*h*.) The givers of the notice may from time to time, if they think fit, require the Undertakers to give them such security for the repayment to them of any expenses to be incurred by them under this section as may be agreed upon between them and the Undertakers, or in default of agreement as may be determined by arbitration. If the Undertakers fail to give any such security within seven days after being required to do so or in case of difference after the delivery of the arbitrator's award, they shall not be entitled to serve any further requisition upon the givers of the notice requiring them to exercise or discharge any powers or duties under this section, until such security has been duly given.

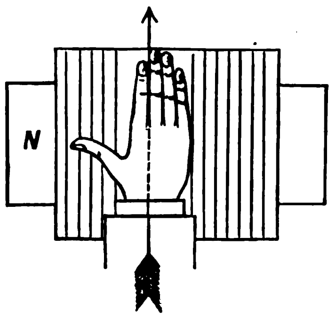
Provided that nothing in this or the last preceding section shall in any way affect the rights of the Undertakers to exercise or discharge any powers or duties conferred or imposed upon them by this License or the principal Act, in relation to the execution of any works beyond the actual breaking up, filling in, reinstating, or making good any such street or part of a street, or any such railway or tramway, as in this section mentioned.

(*To be continued.*)

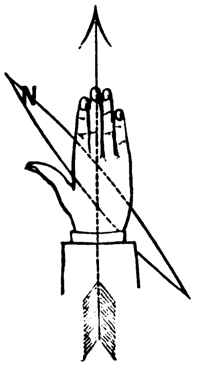
RULE OF THUMB FOR FINDING DIRECTION OF CURRENT AND NORTH POLE OF MAGNETS.

BY J. D. F. ANDREWS.

Knowing the direction of current in the wire of an electro-magnet, then the thumb of the right hand will point to the N. pole when the palm of the hand is placed on the coil, with the fingers parallel to the wires, and pointing in the direction of the current.



Knowing the N. pole of a magnet, then the fingers will point in the direction of the current when placed parallel with the wires, with the palm of the hand on the coil and the thumb pointing to the N. pole.



The N. pole of a magnetic needle will deflect towards the thumb of the right hand when the palm is placed on the wire, with the fingers parallel to it pointing with the direction of the current producing the deflection. Conversely, if a magnetic needle deflects towards the thumb of the right hand, with the palm on a wire over the needle and the fingers parallel with the wire, then the fingers will point with the direction of the current. The above rules are exceedingly handy in the construction of dynamos, and are easily remembered by workmen who have to connect up the coils, &c.

ELECTRICAL SAPONIFICATION.—Professor Rotondi has recently completed his experiments upon the application of electricity to the decomposition of concentrated salt solution into caustic soda and chlorine gas for commercial purposes. He has found that with a dynamo and diaphragms the process of saponification is easily effected by means of common salt and fat. The separation of the resultant products, glycerine, soap, and chlorine gas is a matter of no difficulty. No caustic soda is necessary for saponification.

LIGHTHOUSE ILLUMINANTS.—ELECTRIC LIGHT APPARATUS.

REPORT OF PROF. W. GRYLLS ADAMS, F.R.S., &c.

(*Continued from page 78.*)

According to Fresnel's formula the reflection of light from the surfaces of this lens amounts to 8·3 per cent. of the whole; hence in using this photometer the illuminating power of the arc may be determined within a distance of 5 feet from the arc, and 8·3 per cent. must be added on to the results obtained to allow for the light reflected from the surfaces of the glass.

In order to test the accuracy of the method, measurements of the light were taken with the lens at different distances from the arc, thus introducing a different multiplying factor for each case.

Thus, with the lens at a distance of 100 inches from the arc, the value $\left(\frac{u-f}{f}\right)^2 = 2,607$, several series of observations were made for intensity of illumination. The difference of colour of the lights was got rid of by observing through ruby glass and also through the blue solution of ammonia sulphate of copper.

The following were the results :—

For red light, 16,440 candles.
For blue light, 35,660 candles.

Another set of observations was made with the lens at a distance of 73 inches from the arc.

The multiplying factor in this case was 1,354.

The following were the results :—

For red light, 15,934 candles.
For blue light, 36,030 candles.

Observations were also made with an orange glass, which gave an illumination of 19,900 candles.

For the sake of comparison with these measurements, a series of measurements was also made with the pentane gas flame and the shadow photometer, making observations of the shadows by looking through the same red glass and ammonia sulphate of copper solution to see when the shadows were of equal intensity.

The observations were made in the photometric gallery at a distance of 140 feet from the arc, and the mean results arrived at were :—

For red light, 12,300 candles.
For blue light, 20,580 candles.

On the same day Sir J. Douglass compared his standard light with the catoptric light from a 21 inch reflector and double-wick Douglass oil burner, and found the catoptric light to be 6,130 candles.

He then compared directly the catoptric light with the electric light by means of Bunsen's photometer, and this gave an illumination of very nearly 18,390 candles for the light of the electric arc.

During these experiments the average E.M.F. at the extremities of the arc was 35 volts, and the average current 180 amperes from machine L No. 2, giving 6,300 as the average power in watts.

Measurements in the Photometric Gallery.

On November 10th measurements were again made to test the efficiency of the machines and the power employed in driving them when supplying an arc in the photometric gallery. Three separate determinations showed that 13·8 h.p. was consumed in producing 170 amperes of current with an electromotive force of 43 volts at the terminals of the machines, giving the average power of 7,300 watts.

This gave an electromotive force of 35·5 volts at the extremities of the arc, making the average power consumed in the arc about 6,030 watts. The light given in this case, as measured by red light, was 8,230 candles, and by blue light 18,600 candles.

Two machines were then employed to supply one arc in the photometric gallery, when there was a consumption of 28·5 h.p., giving a current of 286 amperes, with an electromotive force of 46 volts, giving an average of 13,150 watts in the external circuit.

This gave an electromotive force of 34 volts at the extremities of the arc, making the average power consumed in the arc in the photometric gallery about 9,720 watts.

The light given in this case, as measured by red light, was 16,000 candles, and by blue light was 23,000 candles.

The single engine which was used for these experiments was not found to be powerful enough to drive the three machines at full power.

On December 18th, when employing the three machines in parallel circuit to send a current through one arc in the photometric gallery, the power expended (as deduced from indicator diagrams taken on the engine) was 40·5 h.p. (nett), which gave an E.M.F. of 55 volts and a current of 333 1 amperes, or 18,320 watts, *i.e.*, 24·56 h.p., giving an electrical efficiency of 61 per cent. in the external circuit.

When the two machines, L No. 1 and L No. 2, were worked together under the same conditions as in the previous case, the power expended by the engine was 28·44 h.p., which gave an E.M.F. of 50 volts and a current of 285 amperes, or on an average 14,250 watts, *i.e.*, 19·1 h.p., giving an electrical efficiency of 67·2 per cent. in the external circuit.

This confirms the results obtained under the same circumstances on November 10th.

The efficiency of the single machines was not tried on this occasion.

In measuring the intensities of light in the photometric gallery on December 18th during these experiments, the Douglass standard (1 candle) and the Bunsen or star disc were joined together, and the slit of the Douglass was one foot from the disc. This standard was afterwards measured by the pentane standard, and was found to be 1,093 candles.

A copper ruby glass was made use of in these experiments to compare the electric light with the yellow light of the Douglass burner.

Digitized by Google

With the current from three machines two sets of observations were made at two different distances, *i.e.*, 100 inches and 84 inches from the arc with the Hopkinson photometer; the two values obtained from the mean of these sets were 11,956 and 11,913 candles.

With the current from two machines several distinct sets of observations were made with the Hopkinson photometer, looking at the disc through ruby glass to compare the two lights.

The values obtained were 7,197, 9,183, 8,496, 6,273, and 8,590 candles.

The mean of all these results gives 7,948, or about 7,950 candles by red light.

Engine Room Experiments.

The arc lamp was now transferred to the engine room in order to determine the efficiency of the machines when supplying the electric current to the single arc without having external resistance in the leads.

This will give the efficiency of the machines when worksd as they are intended to be in lighthouses, where the lamp and the magneto machine should be placed not far apart from one another.

An expenditure of 14·2 h.p. gave an electromotive force of 43 volts and a current of 221 amperes, making an average of 9,500 watts, as compared with 170 amperes and 7,300 watts, when the arc was in the photometric gallery.

In this case the electrical energy in the external circuit is equivalent to from 12·25 to 12·75 h.p., and the efficiency is about from 86 per cent. to 88 per cent. (externel efficiency).

A similar experiment was now made with two machines supplying the electric current to one arc in the engine room. The horse-power expended was now found to be 28 45 h.p., giving an electromotive force of 41 volts and an average current of 410 amperes, making an average of 16,810 watts, equivalent to 22·54 h.p., as compared with 43 volts and 285 amperes, or 13,150 watts for the same h.p., expended by the engine when the arc was in the photometric gallery.

In this case, working two machines on one arc, the external efficiency is 79 2 per cent.

These experiments show the great advantage to be derived from placing magneto machines for lighthouse work as near as possible to the electric amp as to make the resistance of the connecting wires as small as possible.

On trying the three machines cn one arc it was found that the engine was not powerful enough to keep the three machines at full power.

On January 24, 1885, experiments were made with the arc lamp in the engine room, and an attempt made to measure the light given out as well as the current and electromotive force.

(1.) With one machine.

The electromotive force, as well as the current, was slightly lower than on December 18th last, the E.M.F. being about 37 volts and the current 222 amperes from one machine, when the light given by the arc was 14,730 candles or 13,450 candles.

Another series of experiments gave an electromotive force of 33·5 volts and a current of 227·5 amperes, giving as the average value 7,620 watts. During this series of experiments the light varied between 13,000 and 17,350 candles, the mean value being 14,000 candles.

(2.) With two machines supplying current to one arc, using the Siemens Berlin core 40 mm. carbons, two distinct sets of experiments were made, first with the Douglass standard candle (1·093 candles according to the Harcourt pentane flame standard), and afterwards with the full opening, giving 4·2 candles.

The first set of observations gave an illuminating power of 32,670 candles, and a second set of experiments gave a mean value of 24,710 candles.

The mean electromotive force was 41 volts, and the current varied from 378 to 414 amperes, the mean current being 395 amperes, giving the average power 15,960 watts expended in the arc.

Some new De Meritens solid 50 mm. carbons were now placed in the lamp, instead of the Siemens 40 mm. Berlin core carbons, with the following results:—

The average E.M.F. for 15 minutes previous with the Berlin core carbons was 39 volts, and the current 404 amperes, and the average light was 24,850 candles. But with the De Meritens carbons the average E.M.F. was 34 volts and the current 420 amperes, the average light being 17,420 candles. The De Meritens carbons did not give as good a light as the Berlin core 40 mm. carbons.

Experiments of February 28th and March 7th in the Engine Room.

In these experiments measurements were made of the electromotive force and current with a single machine and with two machines supplying the electric current to a single arc, and the intensity of the illumination was measured by means of the Hopkinson photometer, making use of the Douglass standard at a distance of 32 feet from the arc. Red and green glasses and a blue solution (ammonia sulphate of copper) were employed to compare the light of different colours given by the electric light and by the standard.

Taking 4·2 as the value of the Douglass standard throughout these experiments, the following are the values of the light given in the experiments:—

On February 28th, with one machine, the following values were obtained:—

E.M.F.	Current.	Light.	Colour.	Means.		
				E.M.F.	Current.	Light.
40	213	7,240	Red	—	—	—
35·3	225	13,980	Green	37	221	13,000
35	225·7	17,950	Blue	—	—	—

On March 7th, under the same circumstances, with one machine, the values were:—

E.M.F.	Current.	Light.	Colour.	Means.		
				E.M.F.	Current.	Light.
42	202	8,230	Red			
40	203·5	12,880	Green	40·2	204·2	12,650
38·7	207	16,830	Blue			
40	203·8	7,230	Red			
37	207·5	17,250	Green	38	206·6	15,960
37	208·5	23,410	Blue			

With two machines, the following series of values were obtained:—

—	E.M.F.	Current.	Light.	Colour.	Means.		
					E.M.F.	Current.	Light.
	46·6	377·7	14,340	Red			
Feb.28	47·5	376·6	32,280	Green	47·8	371·6	30,470
	49·3	360·5	44,790	Blue			
	51·6	354·5	13,080	Red			
	53·6	342·5	27,670	Green	52·2	350·7	29,620
	51·5	355	48,120	Blue			
	50	361	15,320	Red	—	—	—
	50·5	370	15,920	Red			
	52·7	361	24,860	Green	52·5	358·5	28,860
	54·3	344·5	45,800	Blue			
	62	303	13,770	Red			
	50	379	28,320	Green	55·3	343	29,170
	54	350	45,410	Blue			

It will be seen that usually the arithmetic mean of the observations for red, green, and blue light gives a result somewhat less refrangible than green, *i e*, between the yellow and the green in the spectrum.

An attempt was made to estimate the value of the light by direct comparison with the standard without any coloured medium, but it was more difficult to estimate the equality of the lights differing so much in colour.

The values obtained in the observations with two machines arranged for quantity were:—

—::—	E.M.F.	Current.	Light.
February 28...............	48·3	372	27,450
March 7	60	325	18,400
	55	341·4	21,870

There were very considerable variations of the light, depending on the variations of electromotive force and current. It will be seen that as the E.M.F. is diminished, the current increases, and as the current increases the light also seems to increase.

(To be continued.)

PHYSICAL SOCIETY—November 28th, 1885.

Mr. T. H. Blakesley was elected a member of the Society.

The following communications were read—"On the Calibration of Galvanometers by a Constant Current," by Mr. T. Mather. A current is passed through the coils of a galvanometer, which may be of any form; the galvanometer is turned in a horizontal plane through any angle, which need not be recorded, and the deflection θ of the needle noted. The current is then broken, and the needle swings back, taking up its position in the magnetic meridian; the angle through which it turns to do this is also noted, δ. This is repeated with the galvanometer in various positions, and with the same current, and a curve is drawn showing the relation between the values of $\frac{\sin\theta}{\sin\delta}$ and corresponding values of θ. When the instrument is now used in its normal position, it is readily seen that a current producing a deflection, θ, of the needle is proportional to the value of $\frac{\sin\theta}{\sin\delta}$ corresponding to θ obtained in the calibration experiment which may be read off at once from the curve.

"On a Machine for the Solution of Cubic Equations," by Mr. H. H. Cunyngham. This machine the author believes to be the only one hitherto constructed that gives the imaginary as well as the real roots of a cubic equation. A cubical parabola is drawn upon paper the ordinates being the cube roots of the corresponding abscissæ. To find the roots of a cubic, first reduce it by Cardan's rule to the form $x^3 - Ax - B = 0$. Then measure off along ox a distance equal to B, and from this point, T, draw a line, making an angle equal to $\cot^{-1}$ A with ox. The ordinates of the points where this line cuts the curve are the roots of the equation. To find the imaginary roots when they exist, first find the real root, as before; from this point draw a tangent to the branch of the curve the other side of oy, then if this line cut the axis of x at a point Q, and α be the real root, the two imaginary roots are

$$\frac{\alpha}{2} \pm 2\sqrt{\frac{QT}{\alpha}}$$

Digitized by Google

Instead of actually going through the construction as above, the operation is preferably performed by applying a protractor with a tangent scale to the curve with its centre at T, setting it, and leading off the point of the curve cut by its edge.

"On a Machine for the Solution of Equations," by Mr. C. V. Boys. After mentioning Mr. Hinton's apparatus, lately shown to the society, and briefly describing Mr. Kempe's equation machine, Mr. Boys explained a machine he had constructed, consisting of a system of beams, each provided with a pair of pans, and working upon a fulcrum at the middle. The pans of the first beam are marked $+a$ and $-a$, those of the second $-b$ and $+b$, the next $+c$ and $-c$, and so on. Into these, weights equal in value to the coefficients a, b, c, &c., of an equation $a+bx+cx^2+\ldots\ldots=0$ are to be placed. A sliding joint is arranged to connect a point opposite the positive pan of each beam with a rib at the back of the next lower one. Alternate beams are placed opposite one another, and each set can be slid past the other, the peculiar connecting joints being able to slide past the fulcra and the pans on each beam. To solve an equation the coefficient weights are placed in their pans, and the two sets of beams are made to slide past one another. At certain positions the beams change the direction of inclination. These positions of balance are noted on a scale, the readings of which are roots of the equation. When there are not more than two impossible roots the machine will find them; for this purpose the real roots are first found and divided out, the resulting quadrate being placed on the machine. Instead of a change of inclination of the beams a maximum or minimum of pressure is observed by a spring balance. The reading of the scale is then the real part of the root, and the square root of the pressure the impossible part.

Mr. A. Hilger exhibited and described a new driving clockwork of isochronous motion, regulated by a fan-governor, and a new direct vision spectroscope.

LEGAL.

The Provincial (Brush) Electric Light and Power Company v. Shillingford and Bateman.

This case was continued on Friday last, and at its conclusion the learned judge said that the question he was asked to determine was so novel that he would take time to consider it. The action was to enforce the payment of a sum of £53 odd, which the plaintiffs alleged was due to them as the balance of their account with the defendants under a contract between them and the defendants for the installation of the electric light at the defendants' brewery, at Whitney, in Oxfordshire. The defendants, who had paid the plaintiffs £100 of their account, defended the action on the ground that in the contract the plaintiffs had guaranteed their light would be a success, whereas, it was alleged, it had resulted in a complete failure. They also counter-claimed to have £50 of the £100 already paid to the defendants returned, on the ground that it was money paid by mistake of fact, viz., under the belief that the light would ultimately succeed; and they also claimed a sum of £50 as damages for the loss of the expected advantages of the electric light. The plaintiffs admitted that, as a fact, the light had failed, but pleaded that the failure was due to the defendants' own engineer.

Mr. F. King, the acting engineer to the plaintiffs, stated that on examination he found the dynamos in all their parts perfectly satisfactory. The accumulators, he admitted were standing upon iron rods; but that, in his opinion, did not matter, and would not cause leakage of the acid, as had been suggested, because the jars were of stoneware, and the wooden separators having been boiled in paraffin wax, no capilliary attraction could take place. In his opinion the filaments of the lamps were broken by too strong a current, which might be the result of over running, or of running the engine at the same time as the accumulators were being charged. This was shown, he said, by the discoloration of the glass of the lamps in question. The glass would not blacken if the filaments had broken through faulty construction. It was stated that King and Thomson had instructed the defendants' man Baker, who, it was admitted, knew little or nothing of electricity, how to conduct the lighting, and that he was never to permit a greater current than 25 amperes, which the ammeter would show him. It was suggested by the plaintiffs that Baker had neglected these instructions, but no direct evidence of this could be adduced, and the plaintiffs based their contention on the facts, viz., broken filaments with blackening of the glass, frequent melting of the safety fuses and rapid wearing away of the brushes, together with damage to the dynamo. Baker, on the other hand, was called, and produced his instructions, which he swore he had invariably adhered to. It was admitted by the plaintiffs that they had guaranteed a success, which they alleged they had effected so far as they were concerned, and in support of this contention they referred to the lengthy correspondence in the case, commenting on the fact that from the time when the defendants took over the installation, about the end of Sept., 1884, down to Oct. 20, no complaint had been made; and further, that in a letter of Oct. 16 the defendants had said that the light was working fairly well, and on Oct. 20, "Not so good as when started." On Nov. 3 the plaintiffs had sent in their account, viz., £145 odd. This correspondence, however, it should be mentioned, showed that during all this time there were frequent little details going wrong. In answer to the plaintiffs' account, the defendants on Nov. 10 wrote that they would send a cheque as soon as the light worked satisfactorily; and on Dec. 16 the defendants sent the plaintiffs a cheque for £100. This fact was urged by the plaintiffs as an admission that the lighting had succeeded when coupled with their (the defendants') letter of Nov. 10. The dynamo was returned for repair to the plaintiffs on Feb. 6, and shortly after that the whole thing was given up, and in the result the present action was brought, as the defendants refused to pay anything further in respect of the installation. The defendants' case was that from first to last the light had been a failure, for they had understood, it was stated, that the system of storage would have given them a constant light for 10 lamps all night, whereas their manager, who was called, stated that with only 6 lamps running, the light would only last 4 or 5 hours, and with more not 4 hours. He also stated that they (the defendants) had been obliged to supplement the electric light with gas, and that at 6 a.m., when brewing, the light had never been available, and often began to fail at 9 p.m. They also alleged as regarded the electrical plant that—1st, cells of the accumulators insufficient for holding acid; 2nd, brushes wearing out; 3rd, filaments of bad construction; 4th, insufficient connections between the different lamps; 5th, life of lamps too short; 6th, fuses and cut-outs carelessly adjusted; 7th, accumulators insufficient.

In the end, the learned judge declined to go into a great deal of the scientific evidence, remarking that, as he was not an electrician, it would to him be perplexing, ambiguous, and misleading, and he intended to decide the case upon the broad question, regarded from a common sense point of view. His Lordship deferred judgment.

Electrical Power Storage Company v. Elwell-Parker.

In the Chancery Division, on Friday last, before Vice-Chancellor Bacon, Mr. J. C. Graham appeared in an action for an injunction to restrain the infringement of a patent. The case was mentioned in July by the Attorney-General. Since then the defendant had submitted to an injunction, and he (Mr. Graham) was instructed to move for judgment for an injunction during the continuance of the patent.

Mr. INGLE JOYCE said the defendant consented to an order for an injunction to restrain the infringement of the patent; no costs to be granted on either side.

The VICE-CHANCELLOR made the order asked.

The Hydro-Carbon Syndicate (Limited).

In the Chancery Division, on Saturday last, before Mr. Justice Chitty, Mr. Ince, Q.C., appeared in support of a petition by this company for a voluntary winding up under supervision. The company purchased certain electric patents, which did not turn out well; but in the course of the experiments with those patents they discovered other matters which were valuable. The winding up was with a view of the formation of another company, the present company having spent all its capital, and it had been resolved upon by resolution of a general meeting of the shareholders. There was no opposition.

Counsel for shareholders and creditors stated that they did not oppose the petition.

The JUDGE: Do you say there is a surplus?

Mr. INCE: Oh, yes.

The Judge granted the order asked.

COMPANIES' MEETINGS.

Blackpool Electric Tramway Company.

The first annual meeting of shareholders of this Company was held at the offices, Blundell-street, on Saturday afternoon last, Mr. Alderman Richard Horsfall (Mayor of Halifax), Chairman of the Company, presiding.

The SECRETARY (Mr. R. Handley) read the report of the Directors.

The CHAIRMAN moved the adoption of the report and balance-sheet as circulated.

Mr. BANNISTER (Manchester) seconded.

Dr. KINSBURY said that before the balance-sheet was approved of he and other shareholders would like to have some information on several of the items which he thought required some explanation. Under the head "Capital and Liabilities" he saw that there was owing for cars, balance of contract, £140; he would like to have some little information upon that. The next item read "Travelling, hotel, and other expenses, joiners' work, electrical fittings, &c., £171. 16s. 11d." He thought it only fair to the shareholders that that amount should be differentiated, the different items put separately. Items so heterogeneous as hotel expenses and electrical fittings should not be grouped together. The £888 owing to the Preston Bank he supposed would be only an ordinary overdraft. Then there was a *nota bene* to the effect that there were other liabilities, approximated at £2,000, the amount of which had not yet been eventually settled or ascertained. He considered that very unsatisfactory—they might be owing £15,000 as far as the shareholders were able to say. In the property, assets, and preliminary expenses there were several items which required explanation. The first item was £1,000, on account, to the contractor for building the tram shed. He would like to know what was the balance owing, and who was the contractor. Another item was "architects, £60 on account." Surely, it did not take two architects to construct or plan that shed. How much balance was owing? For generators, motors, £500 had been paid on account. He wanted to know what was still owing, whether the motors were working satisfactorily, or whether any cost would be incurred by the Company in replacing them if they did not. In connection with the

Digitized by Google

centre channel he saw that £4,000 odd had been paid on account for electrical fittings. It was a very large item to pay on account, there might be another £4,000 owing, so that he wanted some information. The contractor had received £600 on account of laying the centre channel—how much more was to pay? The next items was "Mr. M. H. Smith on account of consideration for the assignment of the Corporation concession and patent right for Blackpool, £500; engineer's commission, on account, £400." He supposed the £500 would be under the original agreement, but he could not understand the £400 for engineer's commission. What was the balance due, and under what agreement was the amount paid? Under the head preliminary expenses there was the item "travelling, hotel, and other expenses, £213. 16s. 4d." He wished to know what was the relation between that item and the item of £171 in the capital and liabilities account. He thought the balance-sheet most unsatisfactory—he had never seen a balance-sheet so skilfully designed as to leave the owner of it in a state of ignorance as to the real facts of the case. He would move that it be referred back to the directors in order that it might be so prepared as to show on the face of it in what sum the Company was already indebted.

The CHAIRMAN said thst he was glad that Dr. Kingsbury had taken the interest he had in dissecting the balance-sheet. Of course at a first meeting it was a difficult if not an impossible matter to furnish a true and correct statement of liabilities. He thought the *nota bene* explained itself. In addition to the liabilities shown on the balance-sheet there were others estimated at £2,000. £1,800 had been paid the contractor, Mr. Cardwell, but since the accounts had been prepared the balance had been ascertained to be £348, and he had been paid that sum. They had a contract with Elwell, Parker, and Co. for motors. Some had been supplied and some had not. The earlier ones supplied did not work satisfactorily, but since then alterations had been made, and the motors were now working exceedingly well and most satisfactorily. They had been paid a certain sum on account, and the balance due to them when they had completed their contract would be, he thought, about £700. There was a balance due to Smith, Baker, and Co. for electrical fittings of £400, as near as they could ascertain. On the accounts sent in by Mr. Copley, the contractor, there was a balance due of £210, but that they expected to reduce. The balance due to the engineer was about £100, and instead of being £2,000 as approximated on the balance-sheet he thought their total debts would amount to about £1,700. He thought that statement would explain all questions that Dr. Kingsbury had raised with respect to payments on account.

Mr. R. HANDLEY read the various items which made up the £171 classified as travelling and other expenses. The Directors' expenses out of pocket amounted to £42, and the rest was made up of payments for electrical fittings, joiners' work, printing, &c. The item of £213 under the same head on the assets side included expenditure, which had been actually paid, and items which had not been paid. The £171 was all outstanding; it had not been paid.

The CHAIRMAN said that the balance owing for architect's fees was about £40. He did not know exactly. In answer to questions as to the motors, he said that those first sent by Elwell, Parker, and Co., did not answer, but they had now got an improved motor, which was most efficient. Their contract with Elwell and Parker was most stringent, and the Company would not suffer any loss because of the failure of the first motors supplied. The travelling expenses of the ten Directors during the twelve months did not average more than £4 each. They had charged for nothing except bare expenses out of pocket. £400 had been paid Mr. M. H. Smith as his commission—5 per cent. upon the electrical work of the central channel, and 2½ per cent. upon the engine and cars. There was still about £100 owing him.

Dr. KINGSBURY said he would be sorry to make any objection, but how did they come to pay Mr. M. H. Smith anything at all for commission? He had never seen anything mentioned as to Mr. Smith receiving a special commission.

The CHAIRMAN said that he was rather surprised to hear a gentleman in Dr. Kingsbury's position raise a question of that kind. Mr. Holroyd Smith had been a resident in Blackpool nearly all the summer. They had had two or three assistants who had been carrying out the work, and of course he had them to pay. Surely if they engaged an engineer to construct works they must pay him for the labour and time he spent upon them. He knew that Mr. Smith was not satisfied with the way in which the Directors had pulled up his accounts and cut down his commission, but still they had their duty to the shareholders to consider.

Mr. E. DEAN said that he had not seen the agreement which had been entered into between the company and Mr. Smith. He wished to know if the £2,000 was to be paid to Mr. Smith irrespective of whether his mode of working the line was successful or not. As he understood it, new motors were rendered necessary because of the failure of the proposed system of working the cars.

The CHAIRMAN said that Mr. Dean was under a misconception. The failure of the first motors supplied by Elwell, Parker, and Co., was due to a delicate bit of machinery which gave way. They were not constructed according to Mr. Smith's specification—Elwell and Parker thought they had a better idea, but it had turned out a failure. The motors were reconstructed in accordance with Mr. Smith's instructions, and they were working successfully. The Company would be to no cost on account of the experiment of Ewell, Parker and Co.

In answer to Dr. Kingsbury, the CHAIRMAN said that they, the Directors, agreed with Mr. Smith to pay him engineer's commission on the works, in order that he would give special attention to it.

In answer to Mr. Deacon (Bolton), the CHAIRMAN said that they would have to pay Mr. Smith the amount agreed upon for his patent right, whether his system was a partial or a total failure. On the other hand, however, they did not admit that it would be a failure—they were very well satisfied that it would not be a failure. In reply to another question the Chairman said it was not true that the Corporation and that Company were at great variance. He was glad to say that they were working very harmoniously together—the Corporation was meeting them in every possible way they could. The delay had arisen partly from difficulties the Corporation had experienced, and they were partly to blame as well.

Ultimately the adoption of the balance-sheet was agreed to.

The CHAIRMAN said the retiring Directors were Messrs. Bickerstaffe, Broadbent, and himself. Mr. Hyde had given notice that he intended to propose the appointment of Dr. G. C. Kingsbury as a Director. That morning, however, the Directors had received the resignation of Dr. Scholefield, of South Shore, and they recommended the appointment of Dr. Kingsbury in his place.

Mr. HYDE said in that case he would propose the re election of the three retiring gentlemen, and the election of Dr. Kingsbury in the place of Dr. Scholefield.

The motion was seconded and agreed to.

Messrs. J. D. Taylor and Co., Halifax, were re-appointed auditors to the Company.

Mr. HYDE said that a question which had been giving him much anxiety of late was as to the rights of renewal the Company had at the end of seven years.

The CHAIRMAN said that if the Corporation decided to purchase their electrical plant, and themselves to work the line, they had to give them notice in writing within the first three months of the last year of the term of seven years for which it was leased to them. If the Corporation failed to give notice the Company would give notice within the second three months of the last year, requiring a continuation of the terms of the lease for another seven years. The same proceedings would take place at the end of 14 years, and at the end of 21 years the power of the Corporation to buy the electrical plant would expire. He (the Chairman) thought that it was a most satisfactory agreement.

The proceedings concluded with a vote of thanks to the Chairman, who expressed the hope that at their next meeting they would be able to declare a satisfactory dividend.

NOTES.

THE EARTHQUAKES IN ALGERIA.—Another shock of earthquake has been felt in the Msila district of Algeria.

THE ELECTRIC LIGHT IN BRAZIL.—An installation of the electric light has been put down at Rio Claro, Brazil.

THE ELECTRIC LIGHT AND MINES.—The works of the Alice Mining Company, Silver Bow County, Montana, are now electrically lighted.

THE TELECTROSCOPE.—Such is the name of the electrical instrument of the future, by means of which we are to see at an infinite distance.

SELF DECORATION.—Electric shirt studs containing a small incandescent, fed of course by a pocket accumulator, are among the latest novelties.

STRUCK BY LIGHTNING.—Mr. Skinner, a conductor in the Commissariat Department, and his son, have been killed by lightning at Jubbulpore.

BURMAH.—All telegrams referring to the condition of the upper province are subjected to the censorship of the military authorities at Thayetmyo.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 11th inst., amounted to £2,931.

A COURSE OF LECTURES.—We are informed that M. Bouty has opened a course of lectures at the Collège de France, Paris, on the "Mechanical Theory of Heat, Magnetism, and Electricity."

OBITUARY.—We regret to hear of the death of Mr. Henderson, Chairman of the India Rubber, Gutta Percha, and Telegraph Works Company. The funeral took place yesterday (Thursday).

THE TELEPHONE AND THE ADMIRALTY.—Experiments are about to be made at Portsmouth with the view of extending the use of the telephone in the dockyard, the electric shop being the central exchange.

THE SOUDAN TELEGRAPHS.—A telegram from Wady Halfa states that the telegraph to Kosheh is open.—The telegraph line south of Akasheh is cut, but heliographic communication has been established.

RIPON.—It is proposed to build a new public hall at Ripon. The artificial lighting has not been decided upon, in view of the suggestions made by members of the Corporation to adopt the electric light in the city.

THE GREAT FIRE IN SOUTHWARK.—In connection with the great fire which broke out recently in Southwark, it is stated that the heat of the flames was so intense as to cause some telegraph wires to fall into the street.

H.M.S. "COMUS."—Orders have been received at Sheerness port directing the "Comus," 14, unarmoured screw corvette, 2,380 tons, 2,450 horse-power, attached to the Fourth Division of the Medway Steam Reserve, to be fitted with the electric light.

THE WHARVES OF NEW YORK.—Visitors to New York City should pay a visit to the river front. Along the North and East Rivers and the Battery is an almost continuous chain of arc lights, which thoroughly and effectually illumines the wharf line.

EDISON'S LATEST.—Mr. Edison, having found the cares of business to weigh far too heavily upon him, has finally decided that in his case a partnership offers many advantages. He is about to be married, and to an interesting and accomplished young lady.

THE TELEPHONE IN SPAIN.—It has been decided that on and after the 1st of January, 1886, the quota of subscription for each of the telephone exchanges mentioned in Articles 7 and 8 of the law of the 12th of August, 1884, shall be 300 pesetas per annum.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 11th December were £2,252, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

A NEW CATALOGUE.—We have received a large and well illustrated catalogue of the manufactures of the Brush Electric Company of Cleveland, Ohio, U.S.A., giving a full and clear description of the various apparatus entering into the Brush Electric Lighting system.

THE PERSIAN TELEGRAPHS.—Advices from Teheran state that a Convention has been concluded with the Persian Government whereby the English are to assume the temporary management and maintenance of the Meshed telegraph, which is greatly in need of overhauling.

BIEN BON MARCHE.—An electric lighting company in Germany, who have acquired the rights in that country of the Ganz transformateurs, gravely announces that installations upon this system are *several hundred times* cheaper than upon any other system in existence.

DOMESTIC LIGHTING.—We are pleased to be able to announce that Aldenham Park, Bridgnorth, is to be partially lighted with the electric light. Mr. F. Geere Howard, of Cleveland-street, W., a gentleman well-known to many of our readers, has been entrusted with the carrying out of the work.

BOOKS RECEIVED.—"Notions Générales sur l'éclairage Electrique," par Henry Vivarez; second edition. Paris, J. Michelet. —"Dynamo-Electric Machinery: A Manual for Students of Electrotechnics," by Silvanus P. Thompson, D.Sc., B.A.; second edition, enlarged and revised. London, E. and F. N. Spon.

THE ELECTRIC LIGHT IN CHICAGO, U.S.A.—The contract for extending the electric light system in the Government building in Chicago was let November 13th to the United States Company, at 8,500 dollars. One hundred and twenty-five 16 candle-power lights and twenty-five 150 candle-power lights will be put in.

IN THE ORGANIC WORLD.—The distribution of electrical force in living organisms is a subject that calls aloud for investigation. We have an electric plant, an electric bug, an electric slug, and three electric fishes, to say nothing of the electrical systems of all animals. About these things we know just next to nothing.

THE AFFAIRS OF OPPERMANN BROS.—We learn from the *London Gazette* that the trustees appointed by the High Court of Justice in Bankruptcy, in the Matter of Oppermann Brothers (in liquidation), are Henry Alabaster, of 22, Paternoster-row, E.C., and Charles Henry Walker Biggs, of 1, Salisbury-court, E.C.

RECKENZAUN'S ELECTRIC TRAM CAR.—We learn from our Berlin correspondent that the first trials of this car on the line Brandenburger Thor-Moabit-Ausstellungspark took place a few days ago in the presence of the directors of the Berlin Tramways Company and of the Municipal authorities. The trial was a perfect success.

ELECTRICITY AND MINES.—The Zankerode Mine at Plauen, near Desden, has an electric railway, the coal being conveyed

Digitized by Google

700 to 800 yards by one of Siemens and Halske's electric locomotives. The distance is traversed in about four minutes, and the journey is made fifteen times a day, during which time about 200 tons are transported.

THE TELEGRAPH BATTALION.—Official orders were received at Aldershot on the 14th inst. for Lieutenant Frederick Gilbert Bowles, eighteen sergeants, corporals, and sappers of the Telegraph Battalion Royal Engineers, to proceed to Portsmouth forthwith and embark for special service in Egypt. They left Portsmouth on the 16th inst.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO.—This company notify that the coupon on their 5 per cent. Australian Government Subsidy Debentures, due on the 1st January next, will be paid on and after that date at Messrs. Barclay, Bevan and Co., 54, Lombard-street. Coupons must be left three clear days for examination.

TELEGRAPH POLES.—We are informed that the tenders of the following firms have been accepted for the supply of next year's telegraph poles to the Postmaster-General:—For delivery in London: Mr. E. Rasmussen, Porsgrund, Norway. For delivery on the Tyne and at Perth: Messrs. Calder and Co., Glasgow. The tenders for creosoting have not yet been decided.

A NEW USE FOR THE TELEPHONE.—The *Metropolitan* says that the sick chamber may be enlivened by using a very clever adaptation of the telephone which Messrs. Cordner, Allen and Co. have invented. It is inexpensive, readily adjusted, and conveys the faintest whisper. The *Lancet* gives a very favourable account of it, and recommends the invention to the special attention of surgeons and others.

THE LATE SIR WILLIAM SIEMENS.—A biography of the late Sir W. Siemens is being prepared, at the desire of the executors, by Dr. William Pole, F.R.S., honorary secretary of the Institution of Civil Engineers, and author of the life of Sir William Fairbairn. Dr. Pole will be grateful for the loan of any of Sir William's letters, or for any information of importance. Address Athenæum Club.

THE TELEPHONE IN SWEDEN.—It is stated that Princess Victoria of Sweden has had the telephone installed between her residence and the royal chapel in the castle, as her health does not always permit of her leaving the house to attend Divine worship. Receivers are placed in various parts of the chapel, and the sound is transmitted very satisfactorily, so that the princess is enabled to follow and enjoy the service.

ELECTRO-DEPOSITION.—The admirable work, by Dr. Gore, entitled "Theory and Practice of Electro-Deposition;" including every known mode of depositing metals, preparing metals for immersion, taking moulds, and rendering them conducting, has been revised by a competent authority, and will be republished early next year. We advise all of our readers to secure a copy, as it is the best book by far that has ever been written upon this subject.

THE ALARMING FIRE AT LEEDS.—Notwithstanding the most energetic and prompt efforts of the fire brigades, the fire which broke out in the chemistry lecture-hall at the Yorkshire College at Leeds on Monday night continued for nearly four hours. The damage is estimated at nearly £3,000. The fire was apparently caused by the heat given off from two ordinary sunlights similar to those in use at most of the public buildings in Leeds and other large towns.

A NEW ASSOCIATION.—The old students of the Ecole de Physique et de Chimie Industrielles de la Ville de Paris are about to found a society under the title of "Association Amicale des Anciens élèves de l'Ecole de Physique et de Chimie," with the object of promoting amicable relations between workers in these branches of science, and to furnish them with aid where necessary to enable them to carry on their studies, exploit their inventions, or protect their interests

FOOD FOR THOUGHT.—One of the most attractive of the sciences, and one with which we have necessarily much in common, is chemistry. We know of nothing more refreshing after a hard day's work than to relax the mind with a dreamy reflection upon, say, the derivatives of Metanitrobenzenylamidoxime and Metanitrobenzylazoximebenzenyl, or upon the properties of Phenoxydiphenylmethylphosphonium iodide $PMe\ Ph_2\ I.\ OPh$; the OPh being kept prominently in view. Truly we have much to be thankful for.

LOCAL BILLS IN PARLIAMENT.—Among the local Bills to be brought forward during the coming parliamentary session we notice one relating to the Keighley, Bingley, Shipley, and Charlestown Extension Tramways. New lines are proposed by this Bill to be laid down in the districts of Bradford, Shipley, Bingley, Keighley, and Charlestown, and extensions of existing lines are provided for. The promoters also ask to be authorised to use steam, electric, or other power, and to hold and acquire patent and other rights in relation to such power.

MIDLAND INSTITUTE OF MINING, CIVIL, AND MECHANICAL ENGINEERS.—During the course of his inaugural address, the president of this institute, at a meeting recently held, made reference to the application of electricity to various mining purposes, and bore testimony to the usefulness of the electric signal, and the light on the pit bank. There was no doubt that in the not distant future electricity would play a very important part in the working of collieries. A discussion afterwards took place on Mr. Sydney F. Walker's paper "On Improvements in Electric Signalling in Mines."

LIGHTING OF SANDYCROFT FOUNDRY.—The works of the Sandycroft Foundry and Engine Works Company, near Hawarden, have just been fitted up with the electric light by the Maxim-Weston Electric Company. An exhibition of the light was given on the 11th inst., in the presence of a distinguished company. The lights were run for two hours, under the superintendence of Mr. J. J. Tough, works manager to the Maxim-Weston Company, and gave a beautiful, bright, and steady light, which the various superintendents at Sandycroft considered all that could be desired.

GERMAN CABLES.—It is well known that of recent years Germany has been busy in putting long lengths of her telegraph wire underground. The type of cable usually used is a seven strand copper, each insulated with gutta percha. The copper weighs 90lb. to the mile, the gutta percha 76lb The insulated wires are protected with 24 galvanised iron wires, weighing about 4,080lb. per mile, over which is a serving of jute soaked in bituminous compounds. The cable as a whole weighs about 6,100lb. per mile, and has a breaking strain of 4·5 tons. The cables are mostly buried without other protection.

CAOUTCHOUC IN WATER.—Water has no solvent action upon caoutchouc, but by long boiling in this liquid it swells to some extent, in which state it is affected by some solvents with greater facility than in its ordinary condition. Exposed to the air it resumes after a time its usual form, but the desication takes place very slowly. It has been seen that when a sheet of the best masticated rubber is exposed in water, open to the air in diffused light, it will absorb something like 90 per cent of water, and finally become white, opaque, slimy,

Digitized by Google

and sticky. In sea water under the same conditions, its absorption of water is almost *nil*.

THE TELEPHONE AT BOURNEMOUTH.—At a recent meeting of the Bournemouth Improvement Commissioners the Roads Committee reported that the manager and engineer of the Western Counties and South Wales Telephone Company had explained to them the system they proposed for telephone exchange in Bournemouth. The committee saw no objection to the system proposed. Mr. Hutchings objected to the telephone wires being allowed to be above ground, pointing out that they had just asked the Post Office authorities to put their wires underground. Mr. Fisher said they ought not to throw objections in the way of the introduction of a system which would be so obviously for the benefit of the town.

THE ELECTRIC LIGHT IN BLACKPOOL.—The Directors of the Blackpool Winter Gardens and Pavilion Company have decided to illuminate their gardens, fernery, and floral halls during the ensuing season with the electric light; and have appointed a committee to make inquiries as to the best systems, and to report to the Board. These gardens are visited by over 600,000 persons annually from the busy hives of industry in the neighbouring counties of Lancashire and Yorkshire; and the buildings being so admirably adapted for the purpose, it is intended to make the installation an exhibition of all the latest developments and improvements in electric lighting.

THE ELECTRIC LIGHT AND THE SUEZ CANAL.—A telegram from Alexandria says that the new regulations by which steamers with electric lights are allowed to pass through a portion of the Suez Canal at night is a gain of infinite importance. The new regulations laid down by the Canal Company are to the effect that all vessels desirous of navigating the canal at night between Port Said and Kilometre 54, and *vice versâ*, shall carry at the bows an electric projector, throwing a ray to a distance of 1,200 metres, and at the stern an electric lamp capable of illuminating a circle of from 200 to 300 metres in diameter. In addition to these two, electric sidelights must be carried.

THE TELEPHONE IN MINES.—In connection with our note of the 11th inst. on the telephone in mines, we are informed that the instruments offered by the Northern District Telephone Company were specially designed, at the suggestion of Mr. C. B. Clay, of the above company, by Mr. G. A. Mason, of the Consolidated Telephone Construction and Maintenance Company. The set for the mine is composed of a Bell receiver, Blake transmitter, magneto ringer, and generator. The latter is in an air-tight compartment, to prevent any possibility of explosion of fire-damp by sparking. The whole set is contained in a portable box about 18in. square. The great advantage of a magneto call for mining purposes is that the ringer, which must necessarily be open, never sparks.

AMERICAN ITEMS.—The Decatur, Ill., Gas Committee has agreed upon the terms of a contract for tower electric lighting with the Fort Wayne Jenny Electric Light Company.—An experimental electric railway has been laid on Ridge Avenue, Philadelphia, from the depot of the Ridge Avenue line of cars, about three-quarters of a mile out, and the first trial was made during the past week. The car was run over the track, and the officers of the company declared that everything was working to their complete satisfaction.—The *Milwaukee Sentinel* says that a long-distance transmitter is being tested in the local office of the Wisconsin Telephone Company, the same used in the attempt to converse between Chicago and New York. By using the new transmitter a whisper can be heard a distance of 250 miles with the same distinctness that it can by a person in the same room. The telephone company has made a requisition for a number of the instruments, and they will be used on all of the long-distance lines.

THE ELECTRIC LIGHT AND BUILDERS.—On the night of Thursday last a noteworthy instance of enterprise in the building trade was afforded by Messrs. Bradney and Co., Wolverhampton, who are engaged, under a contract, upon the erection of a large theatre at Derby. The building was only begun on the 2nd November; and as it is intended to open the place early in March, Messrs. Bradney have resolved to secure further time by placing an electric light at each of the four corners of the structure, so enabling the bricklayers and carpenters to carry on their work with almost the same facility as during the day. On Thursday only one light was used, but as soon as the whole of the arrangements are complete, the whole of the men will be able to work the entire night through. The engine which grinds the mortar is employed to supply the necessary power; and to further facilitate work, bricks warm from the kiln are used to counteract the effect of the frost. By the adoption of this expedient the severe weather of the last week has been set at defiance.

THE TELEPHONE AND THE QUEEN OF THE BELGIANS.—It is well known that the Queen of the Belgians has for a long time possessed a telephonic installation (on the Van Rysselberghe system) between her Palace of Laeken and La Monnaie Opera House. The other day the company were going through the score of the "Templiers," the new opera by Litolff, which is to be performed for the first time in Brussels. Her Majesty was listening to a magnificent duet in the piece, where the children of Philippe le Bel and Enguerand de Marigny reveal their love for each other, when all of a sudden the telephone dropped from her hands. The talented leader of the orchestra, M. Dupont, finding occasion to admonish the chorus singers, had invoked the name of the Deity in a manner altogether foreign to courtly etiquette. The Queen made a formal complaint, and since that time everything has gone wrong at the opera house. Litolff threatens to retake his MS., and the managers of the theatre also threaten the cancelment of their contract. Beyond all this, the subscribers, now aware that the slightest word they utter will reach the royal ears, have abandoned the green room and wings *en masse*; a very good thing, we should say, for the management.

THE FIRST TELEPHONE IN ARABIA FELIX.—By this time no doubt the gentle Arab is fairly conversant with the telephone, but the case was different when, some half dozen years ago, two of our readers paid a visit to the Sultan of Lahej, at Al Hautah, in the province of Yemen. As a propitiatory offering to the Chief, they took with them a pair of telephones and about a hundred yards of wire, which they ran up between the courtyard of the Mud Palace and the Council Chamber, in which latter some twenty headmen were squatting in company with their master. The first whisper that came through the telephone had the effect of sending them all scuttling away like a swarm of land crabs on the approach of an invader; but they were eventually soothed and brought back again. The sultan, at first highly interested in the "little foreign talking devil," at length grew tired, and complained that it did not speak Arabic. He was assured that it spoke all languages, and in proof thereof a polyglot individual was taken to the other end of the line and made to chant the praises of his Highness in a crescendo, which ran the gamut of the thirty-nine dialects of Arabia. Before, however, the telephone had a chance of properly vindicating its character the Council Chamber was cleared; even the dignity of the Sultan being unable to withstand *too* much magic.

HONOURS.—At a meeting on Tuesday of the Senate of Dublin University, it was resolved to confer the degree of LL.D. (Honoris Causâ) on the Right Hon. Baron Rayleigh, late Professor of Experimental Physics in the University of Cambridge, and now one of the Secretaries of the Royal Society; and on W. Huggins, F.R.S. Dr. Ingram, in submitting the graces as Senior Proctor, said the first name was that of Lord Rayleigh, who devoted himself at first to the study of pure mathematics, in which he became highly distinguished. He afterwards used the skill thus acquired as an instrument of physical research. He has specially studied the subjects of sound and light, was lately professor of experimental physics in the University of Cambridge, and was now one of the secretaries of the Royal Society. Lord Rayleigh was President of the British Association for the Advancement of Science at its meeting in Montreal in 1884. The second name recommended by the Chancellor was that of William Huggins. Mr. Huggins early threw himself with ardour into the line of investigation opened by Kirchhoff and Bunsen—that of chemical analysis. Mr. Huggins had obtained for his researches the gold medal of the Royal Astronomical Society, and had twice been presented with medals by the Royal Society. He has also been awarded the Lalande prize for astronomy by the French Academy of Science, which had elected him one of its corresponding members.

THE ELECTRIC LIGHT AND HEALTH.—At the Parkes Museum of Hygiene, in Margaret-street, Oxford-street, recently, Mr. Eric S. Bruce delivered a lecture on "Health and the Electric Light," Sir Joseph Fayrer presiding. The lecturer stated that the requirements of an artificial light, in order to make it conducive to health, were that it should not be a source of impurity to the atmosphere; it should heat the atmosphere as little as possible; it should be a brilliant bright light, and should be perfectly steady, cleanly, and in no way a danger. Most of those requirements, however, were not met by the forms of artificial light in use; indeed, all lights which were dependent on combustion at the burner were sources of impurity to the atmosphere, and a danger to the public. The electric incandescent lamp, he pointed out, was the only light where they had perfect incandescence without appreciable combustion in the lamp. It possessed all the health requirements of an artificial light, such as an inappreciable heat, purity and brilliancy of colour, steadiness of light, and immunity from danger of fire. The lecturer having shown by experiments the advantages of electric lighting over other illuminants, concluded by tracing the present depression in the electrical market to the experimental nature of the earlier work, the prejudices of the public, and certain drawbacks of the present Electric Lighting Act. At the conclusion of the lecture the chairman, in moving a vote of thanks to Mr. Eric Bruce, said the electric light possessed almost every advantage that was required in an artificial light, and in his opinion it was destined to be the light of the future.

THE ELECTRIC LIGHTING ACT.—At the annual general meeting of the Society of Telegraph-Engineers and Electricians yesterday week, the council reported that they had unanimously passed the following resolution in reference to the Electric Lighting Act, and forwarded a copy thereof to the President of the Board of Trade:—"Resolved unanimously, that the Society of Telegraph-Engineers and Electricians have seen with regret that since the passing of the Electric Lighting Act of 1882 public lighting by electricity has not made that advance in this country which was confidently anticipated, and hence there has not been that stimulus to progress in many branches of electrical science that might have been anticipated, judging from the history of submarine telegraphy. That the society, having had the matter under careful consideration, have come to the conclusion that the restrictions in the Electric Lighting Act have in a great measure contributed to check the advance of public lighting by electricity; and they venture to request the President of the Board of Trade to consider whether these restrictions might not be modified or removed." The council were aware that equally strong representations upon the subject were made to the Board of Trade from other quarters; and they confidently hoped that in the next Parliament the matter would obtain that attention which it deserved, and that some amendments in the Act would be made to render it a help rather than an obstruction, as it was at the present time, to the development of public and domestic lighting by electricity.—The *Pall Mall Gazette* says:—"There are few who will watch with more anxiety the solution of the political problem than those who are interested in electric lighting. Mr. Chamberlain's Act practically put an extinguisher upon the development of that industry by its stringent compulsory purchase clause. That Act has to be amended in the coming session. Electricians would like to be placed upon the same footing as gas companies, free from the threat of compulsory purchase, but they are not likely to get those terms from either party. Lord Salisbury, however, has let drop certain words of encouragement tending to show that he is in favour of affording much more encouragement to the new industry than it has ever yet received. Hence, if the Conservatives retain power, the developement of the electric light may enter upon a new lease of life. Such is the hope of many electricians."

THE ELECTRIC LIGHT IN THE LEEDS MUNICIPAL BUILDINGS.—The Free Public Library as well as a large part of the new Municipal Buildings have for the last two months been lighted by means of the new system of electricity supplied by Messrs. Paterson and Cooper, and a pretty accurate estimate can now be formed as to the measure of success which is likely to attend the new light. The projectors undertook to provide two dynamo machines capable of running 284 lights, each of 20 candle-power, and owing to some dispute which occurred between Messrs. Paterson and Cooper and the Leeds Corporation a good deal of interest has been taken in the system of lighting which is now being used. Sir F. Bramwell, who tested the machines previously to their being accepted by the Corporation, certified that they were quite capable of doing the work required of them. It is satisfactory to state that Sir Frederick's estimate has so far proved quite correct. The light burns with steadiness and brilliancy, and has proved thoroughly satisfactory to those who have to use it. Of course, it would be premature to say that the new dynamos are all that is claimed for them after the comparatively short trial they have had, but there is every reason to believe, judging from their past performance, that they will fulfil every requirement. A careful examination was made a day or two ago, and it was found that the machines were in perfect order, and providing a light which it would be difficult to excel. The Free Library officials speak in the highest terms of it, and it is in this department where the most severe test is made. It is several candle-power better than the last installation, and, at the same time it does not dazzle the eyes. The power is generated by means of two 12 horse-power gas engines fixed in the basement of the building. These engines are coupled, so that, should one of the dynamos get out of order, sufficient power could be generated from one machine to in a great measure compensate for the disabled one. The engines make about 180 revolutions per minute, and the dynamos 1,050 revolutions. Only eight lamps have had to be renewed in two months—a by no means large percentage. The lamps are the Alexandra, and

Digitized by Google

give a light of exceptional steadiness and brilliancy of 100 volts. It may be mentioned that each dynamo machine is capable of giving an electrical output of 9,000 watts, equal to 142 lights of 20 candle-power, and of running twelve hours continuously without overheating. So far as can at present be judged, says a contemporary, the Corporation of Leeds have as good a system of electric lighting as there is in the country.

The Lighting of the City.—The following are the heads of the proposition made and (we understand) agreed to between the Commissioners of Sewers and the Anglo-American Brush Electric Light Corporation, dated the 12th November, 1885:—The company proposes to supply electric lighting to an area bounded on the north by Fleet-street, Ludgate-hill, St. Paul's-churchyard, Cheapside, Poultry, extending eastwards as far as the Royal Exchange, and bounded on the south by the whole length of Queen Victoria-street and the Victoria Embankment as far westwards as the City Boundary. The company to substitute electric lights for the existing gas lights in the main thoroughfares, and to use electric arc lamps of 2,000 candle-power each, to be placed not more than 60 yards apart, unless otherwise required by the commission. To maintain these lamps and keep them alight from sunset to sunrise at a cost of £26 each per annum. The existing arrangements for gas lighting are not to be disturbed, but to be left capable of being used if needed. Any expense incurred by the commission in consequence of the failure of the electric light is to be refunded by the company. The contract with the commission for public lighting to be in force for seven years, and the commission to have the right to renew the contract on the same terms for a further period of seven years, and also to have power to terminate the arrangement on certain terms to be mutually agreed upon. The company to have the right (but not the exclusive right) to supply electricity to all houses and public or private buildings and premises within the district, and to have free wayleave for their necessary works. The company to have the free use of the lamp-posts and subways under the control of the commission, and the commission is to give them every facility for carrying out the work. The company will extend the arc lighting to any of the other streets required by the commission, but the commission may continue the use of gas in those streets if it prefers doing so. The commission is not to incur any cost in respect of the installation of the works of the company. The *Daily News* understands that the report of the City engineer on this subject, submitted to the meeting of the Commissioners of Sewers on the 1st inst., is distinctly averse to the immediate adoption of lighting by electricity for street purposes. Colonel Haywood deprecates the proposal of the commissioners to undertake to supply electricity, since he considers it would at once bring them into competition with a rich and powerful company, able without much injury to its finances to reduce the price of gas one-half, and would by so doing frustrate the object of the commission in undertaking to supply an economical illuminant. The commission, in his opinion, would better further its ulterior object by exerting its influence to obtain a repeal of the the Electric Lighting Act, to which he attributes the existing stagnation of electrical enterprise in England.

An Electric Safety Lamp for Miners.—A meeting of the North of England Institute of Mining and Mechanical Engineers was held in the Wood Memorial Hall, Newcastle, on Saturday the 12th inst., when Mr. Joseph W. Swan exhibited portable electric safety lamps for miners, and said that at a meeting of the institute, four years ago, a form of lamp, which required a separate supply of electricity to be conveyed to it through a flexible cord enclosing two wires, was shown. A member of the institute criticised the feature of the dependence of the light on an extraneous supply of electric power, and expressed the opinion that the value of the electric light in mines would be greatly enhanced if the lamp and the supply of electricity to it could be combined in one apparatus. The apparatus now before them was a lamp and battery combined, capable of giving during ten or twelve hours twice or three times the light of a common safety lamp. On first lighting it gives the light of two candles, and after ten hours about one candle and a half. For regular mine working the cells were of lead and lead oxide. This kind of cell is a secondary cell Another kind of cell can be used, composed of zinc and lead oxide, with a special view to the occasional employment of the lamp for exploration in vitiated air. This is a primary cell, and only requires filling with liquid to make it ready to give light. It will sometimes be convenient to have a duplicate lamp within the bull's eye, with a switch connection to enable either, but not both, to be lighted, so that in case a lamp should fail the miner will not be left in the dark. The speaker had hoped to have been able to show a fourth modification, in which there are only two cells, instead of seven, to light a lamp. By this arrangement the weight is diminished to between 5lb. and 6lb. Believing that a good light was the most important point to be gained, after safety, the electric lamp shown had been to give two or three times the light of the ordinary lamps, and consequently it was heavier; in fact, weight was made subordinate to light. The apparatus could have been made much lighter if it had been permissible to employ a primary battery instead of a secondary one; but it appears to be only allowable to use a primary battery to meet sudden emergencies, and in those cases where there is no dynamo and no regular system in operation for charging secondary batteries. For mine exploration, where the air is very foul, as, for example, after an explosion, which has destroyed the ventilation of the mine, a lamp with a primary battery, in conjunction with a Fleuss breathing apparatus, will probably be found very useful. But as a substitute for the ordinary safety lamp for general underground lighting, a battery which requires, each time it is used, to have the spent charge emptied out, and a fresh charge poured in, and which also requires frequent renewal of the positive plate of each cell, is impracticable. On the other hand, a secondary battery can be charged with even less trouble than attends the trimming of an oil lamp. Hundreds of lamps can be charged at a time and at very small cost. An engine developing an effective five-horse power, and a dynamo-electric machine, correspondingly small, would suffice to charge 300 lamps at one operation. A discussion followed the reading of the paper, in the course of which the president, Mr. G. Baker Forster, and others spoke in favour of the lamp. Mr. Forster said he had no objection to the lamp as to its construction, and the weight might be got over.—Some of the speakers stated that one objection to Mr. Swan's lamp was that it could not be used in detecting the presence of foul air.—Mr. Swan explained that he hoped soon to add to his lamp an apparatus to detect foul air, and he had hopes of being able to reduce the weight of the lamp.—On the motion of the President, seconded by Mr. Baker Forster, a vote of thanks was passed to Mr. Swan, who, in returning thanks, said that he felt very much encouraged by the way the meeting had received the lamp, and he would prosecute his experiments further, in the hope that at some future time—and perhaps not a very distant time—he would be able to show them a still further development of the lamp.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 88.)

In the electromagnetic scheme we have the equations of a dynamical system, involving the potential energy of elastic displacement (or of electric polarisation, if that very vague term be preferred ; *any* vector function may be made up of polarised elements, whether it be solenoidal or polar, so it is as well not to attach too much importance to the idea of polarisation), the kinetic energy (or magnetic energy), probably of a rotational motion, and dissipation of energy by forces analogous to frictions proportional to velocities, when the electric current in a conductor is taken as a generalised velocity. There is nothing peculiarly electrical until we specify the connections of the different magnitudes. It is one out of the infinite number of dynamical systems subject to $Q+\dot{U}+\dot{T}=0$; the general equation of activity when no energy is communicated to the system, nor allowed to be withdrawn except through the irreversible frictional forces.

The three qualities to which c, μ, and k refer, relate to the potential energy, the kinetic energy, and the dissipativity. In order to render practically simple the theory of special cases, it is necessary to place restrictions upon their values, restrictions that we may know to be untrue. This is perfectly legitimate, as it is the common sense procedure in all matters of reasoning to simplify as far as possible. But it becomes necessary to be careful in the interpretation of the extreme results of a limited theory.

Consider, for example, the discharge of a condenser through a wire. The first approximation to its theory is got by ignoring inertia. If q_0 be its initial charge, that left at time t later is $q_0\epsilon^{-t/t_1}$, where t_1 is the time constant, the product of the capacity of the condenser and the resistance of the wire. An appropriate mechanical illustration is the restoration to equilibrium of a bent spring of negligible mass in a viscous fluid.

But if we push this to extremes, by shortening the discharge wire indefinitely, this theory says that the discharge will always be of the same character, though finally instantaneous. This is entirely wrong. The influence of inertia may be negligible when the resistance is great, but is not when it is small. We allow for inertia by introducing the coefficient of self-induction of the circuit, bringing in an electromotive force proportional to the rate of decrease of the current. Then we find that when the resistance of the wire is below a certain value, the discharge becomes oscillatory. This is quite correct, and the theory as amended is then true within a far wider range than before. But it, again, must not be pushed to extremes. It shows that if the resistance be reduced to nothing, whilst the coefficient of self-induction of the circuit is finite, as it must be, the oscillations continue for ever undiminished in strength, with frequency $(sp)^{-\frac{1}{2}}$, if s be the coefficient of self induction and p the capacity of the condenser. *I.e.*, short-circuiting a condenser would never get rid of its charge, except momentarily, when the energy is all kinetic. Here, of course, the objection is that we cannot indefinitely reduce the resistance in circuit, on account of the resistance of the metallic coatings, previously neglected, when the external resistance was great in comparison. Allowing for that, we still have oscillatory subsidence. But when we consider further that a short-circuited condenser can scarcely be treated as a *linear* circuit, and that we have ignored the dissipation of energy by the oscillatory phenomenon in the magnetic field producing vibratory electric currents in neighbouring conductors, we see that the complete theory of a short-circuited condenser may be only roughly represented by taking into account three constants, the capacity of the condenser, the self-induction coefficient, and the resistance coefficient. What is true enough within certain limits (or uncertain, because no definite line can be drawn between the true and the false) may be wholly untrue beyond them, owing to circumstances of the minutest previous significance becoming then of (relatively) paramount importance.

Retardation in a $\mu=0$, $c/k=$ constant, medium.—This is a very singular case, and of considerable interest. In general, we have

$$\text{div.}\left(4\pi k+c\frac{d}{dt}\right)\text{E}=0,$$

to express the continuity of the true electric current, E being the electric force, k the conductivity and c the specific capacity.

It will be convenient to put $c/4\pi=p$. The new quantity p is the capacity per unit volume considered as a condenser. We may avoid ambiguity by using the word "specific" in connection with c, in the absence of a better nomenclature.

In any normal system $\frac{d}{dt}=n$, a constant, so that the above becomes

$$\text{div.}(k+pn)\text{E}=0; \quad \ldots\ldots \quad (117)$$

or, since the displacement is $\text{D}=p\text{E}$,

$$\text{div.}(k/p+n)\text{D}=0. \quad \ldots\ldots \quad (118)$$

Now, if there be no inertia, or $\mu=0$, and no impressed forces, we shall also have

$$\text{curl.E}=0, \qquad \text{or curl.D}/p=0. \quad \ldots \quad (119)$$

In (117), $(k+pn)$ is a function of position, k and p being variable from place to place, whilst n is constant. Apply Sir W. Thomson's theorem of determinancy. If $(k+pn)$ be everywhere positive, the only solution of (117), subject to the first of (119), is $\text{E}=0$. Similarly, if $(k+pn)$ be everywhere negative, the only solution is $\text{E}=0$. In both cases the point of the demonstration is that $\Sigma(k+pn)\text{E}^2$ is necessarily positive if $(k+pn)$ be everywhere positive, and negative if it be everywhere negative. This quantity $\Sigma(k+pn)\text{E}^2$ is $Q+\dot{U}$, and is therefore zero. It follows that in any normal system $(k+pn)$ must be positive in some parts of space and negative in others (unless it be zero everywhere). Therefore, if k_1/p_1 be the least, and k_2/p_2 the greatest value of k/p, it follows that (k_1/p_1+n) is negative and (k_2/p_2+n) is positive. Hence the values of n for all the normal systems lie between $-k_1/p_1$ and $-k_2/p_2$. Or, their time-constants all lie between the greatest and least values of p/k. If then p/k is the same everywhere, there is only one rate of subsidence for any initial state, given by $(k/p+n)=0$. [To show that there cannot be imaginary n's, make use of $\text{U}_{12}=0$, $\text{Q}_{12}=0$, applying them to the solutions corresponding to a supposed pair of imaginaries. It follows that the unreal part of the roots is zero, and that the normal functions vanish in the case of equal roots.]

Given that the initial displacement is D_0 in a medium in which p/k is constant, and $\mu=0$, and that it is left without impressed force, we therefore obtain the subsequent state in the following manner. Let

$$\text{div.D}_0=\rho_0,$$

so that ρ_0 is the initial electrification. Find D_1, such that

$$\text{div.D}_1=\rho_0, \qquad \text{curl.D}_1/p=0.$$

D_1 is uniquely determinable by these conditions. Then $\text{D}_0=\text{D}_1+(\text{D}_0-\text{D}_1)$, where (D_0-D_1) is a system of closed displacement. It will subside instantaneously, leaving D_1, which will then subside so that the displacement D at time t later is given by

$$\text{D}=\text{D}_1\epsilon^{-kt/p}. \quad \ldots\ldots \quad (120)$$

The conduction current is $k\text{D}/p$, and the displacement current the negative of the same, so that the true current is zero. It is not a case of propagation at all, every elementary condenser discharging through its own resistance. It is the instantaneous vanishing of the closed displacement that is connected with progagation, it being what would happen if $k=0$ with the same distribution of p. First the displacement readjusts itself to make the electric force polar with the same electrification ; and then what is left subsides everywhere at the same rate, according to (120).

Now, any distribution of impressed force sets up a corresponding distribution of closed conduction current, and, therefore, since k and p are everywhere in the same ratio, of closed displacement, without electrification. But it is only displacement with electrification that has a finite rate of subsidence. Hence there is no retardation whatever in connection with impressed force. However it vary with the time, the corres-

Digitized by Google

ponding displacement will vary with it instantaneously. Evidently this is a case in which inertia is not negligible. Maxwell, Vol. I., treats of the case p = constant, k = constant. The extension to p/k = constant allows us to distribute capacity as we please, and so obtain immediately the solutions of various problems connected with shunted condensers.

Now let there be inertia. Although (119) is no longer true, yet (118) is; and, since $(k/p+n)$ is constant, it may be written

$$(k/p+n)\text{div.D} = 0.$$

There is, therefore, no electrification in any normal system, unless $(k/p+n) = 0$. It follows that if there be electrification initially, the above process of dividing D_0 into D_1 and $D_0 - D_1$ is applicable to give us the part of the subsequent state depending on electrification. Thus (120) is true whether there be electro-magnetic induction or not, the left number, however, being not the complete displacement, but only that depending upon the initial electrification. The other part of the initial displacement, $D_0 - D_1$, will subside, not as before, instantaneously, but according to the nature of the normal distributions other than the $(k/p+n) = 0$ solution, depending upon the distribution of k and μ in space, and also upon the initial state of magnetic induction.

Why (120) is true in spite of inertia, is because there is no true current, the force being polar, and therefore no electromagnetic induction in connection with the electrification solution. As before, no electrification can be produced by any impressed forces, so that the $(k/p+n) = 0$ solution may be left out of account. The retardation in connection with the effects of impressed force will depend wholly upon the other n's.

As a simple application of the preceding, let $k = 0$ everywhere except in a single wire, forming a closed circuit. It is a perfectly insulated dielectric wire whose conductivity may vary as we please along it, provided its capacity vary in the same ratio. Let now k and p signify the conductance and capacity per unit length of wire, and D the total displacement across its section. Then D/p is the electric force per unit length, and

$$\frac{d}{dx}\left(k+p\frac{d}{dt}\right)\frac{D}{p} = 0$$

is the equation of continuity, if x be distance measured along the wire. Or

$$(k/p+n)\frac{dD}{dx} = 0,$$

in a normal system. If then D_0 be the initially given displacement, divide it into D_1 and $D_0 - D_1$, such that

$$\frac{dD_1}{dx} = \frac{dD_0}{dx} = \rho_0,$$

the initial electrification of a cross section, and such that the E.M.F. round the circuit is zero. At time t later, the displacement is

$$D = D_1\epsilon^{-kt/p}; \quad . \quad . \quad . \quad . \quad . \quad (121)$$

the part $D_0 - D_1$, which is closed, and is the mean initial displacement all round the circuit, instantly vanishing (if there be no inertia). As before, there is no true current during the subsequent subsidence. By the "mean" displacement is meant the quotient of the total initial E.M.F. round the circuit by the total inductive resistance, that is $(\Sigma D/p) \div (\Sigma 1/p)$, the summation extending round the circuit.

To corroborate, insert a conductor in the circuit having no capacity. There will now be two normal rates of subsidence, one of which is the previous. If n_1 be the new n, it is given by

$$0 = K + K_1 + Sn_1,$$

where K and K_1 are the conductances of the old and of the new wire, and S is the total capacity of the old wire, *i.e.*, $S = (\Sigma p^{-1})^{-1}$, the reciprocal of the sum of the "inductive resistance" round the circuit. The solution will now be

$$D = (D_0 - D_1)\,\epsilon^{n_1 t} + D_1\epsilon^{-kt/p} \quad . \quad . \quad . \quad (122)$$

As the auxiliary wire is shortened, n_1 goes out to negative infinity. Thus we return to the former instantaneous subsidence of the mean displacement when the whole wire has capacity, (122) becoming (121). When K_1 is finite, there is necessarily electrification somewhere; if not in the old wire itself, then at its ends, where it joins on to the new one. If the circuit be open instead of closed, there will be no instantaneous subsidence in any case; the solution is then (121) with D_0 instead of D_1 on the right side.

Any impressed force in the circuit will only suffer retardation in its effects as regards the n_1 term. It would be very convenient, as well as wonderful, if some ingenious inventor could construct a telegraph cable whose electrostatic capacity should be in the conductor instead of outside it. Having it there, however, a first approximation towards lessening the retardation is to give greater conductivity to the insulating covering. Even a leakage fault raises the speed of working considerably. Nothing is worse for rapid signalling (when pushed to limiting speeds), than the most perfect insulation. The lower it can be made (natural high conductivity, not due to faults which by getting too bad would stop communication) consistent with getting enough current at the receiving end, the better, and much better, it is for the signalling. Of course there are other considerations, but we must return to the immediate subject.

We can easily obtain the effect of inertia in modifying the solution (121). Let s be the coefficient of self-induction per unit length of wire, constant for purposes of calculation, and really so if the wire be circular. Let also k and p be constant. We have only to examine how $(D_0 - D_1)$ the closed displacement subsides, in which alone electro-magnetic induction is concerned. Let Γ be the true current over the cross-section, like D. The electric force to correspond is that of inertia, viz., $-s\dot{\Gamma}$. Hence

$$\Gamma = \left(k+p\frac{d}{dt}\right)(-s\dot{\Gamma}), \text{ or } \Gamma = (k+pn)(-sn\Gamma),$$

in a normal system; and the determinantal equation is

$$spn^2 + skn + 1 = 0,$$

giving the two n's

$$n_1 \text{ or } n_2 = -\frac{k}{2p} \pm \left(\frac{k^2}{4p^2} - \frac{1}{ks}\right)^{\frac{1}{2}}.$$

Besides the closed displacement, the initial current may be arbitrary. Let it be Γ_0. Then at time t later,

$$\left.\begin{aligned} \Gamma &= \frac{\Gamma_0 + n_1(D_0 - D_1)}{2+ksn_1}\epsilon^{n_1 t} + \frac{\Gamma_0 + n_2(D_0 - D_1)}{2+ksn_2}\epsilon^{n_2 t} \\ D &= -spn_1 \times \text{ditto} \qquad -spn_2 \times \text{ditto} \qquad + D_1\epsilon^{-kt/p} \end{aligned}\right\}$$

The current is oscillatory if

$$k/p < 2/(ks)^{\frac{1}{2}},$$

and non-oscillatory if it be greater. This differs completely from the condenser and coil theory; for now we get oscillations by reducing the self induction, whereas in the other case, it is by reducing the self induction that we get rid of oscillations.

Although in this solution we take into account the magnetic field, yet we only regard that part of the electric field that is within the conductor. So that the specific capacity c in the wire must be much greater than in the surrounding air to render the latter negligible.

Art is long, but space is short. The application to shunted condensers is therefore left over.

(To be continued.)

INFLUENCE OF THE MOON ON A MAGNETISED NEEDLE.—M. G. Ligner has made a remarkable communication to the Meteorological Society of Austria. He has ascertained after a number of careful experiments that the moon has an influence upon a magnetised needle varying with its phases and its declination. The phenomenon is said to be more prominently noticeable when our satellite is near the earth, and to be very marked when she is passing from the full to her first or second quarter. The disturbances are at their maximum when the moon is in the plane of the Equator, and are greater during the southern than the northern declination.

THE STEAM ENGINE INDICATOR.—XII.*

BY AMICE.

The hyperbolic curve, which is the form of curve obtained by plotting ordinates of pressure and abscissæ of volume of a successively expanded gas, may be constructed by several graphic methods, one of which we will now take as being the simplest for indicator diagram work, as the lines drawn to divide the diagram into a number of equal parts readily form construction lines.

In the diagram (Fig. 40) let L L be a line representing the atmospheric pressure by its distance above the line V′ V, on a scale of 50lb. to the inch; the line V′ V will then represent the line of true vacuum or of no pressure, and will be 14·70lb. per square inch below L L. The line V′ V, as usual, also represents volume, and the vertical ordinates represent pressure. V′ V may also represent the stroke, or that part of the cylinder through which the piston moves. The length A D is that part of the stroke throughout which steam is admitted to the cylinder. Upon A D erect the verticals A B and D C, their height being such as to represent, say, 75lb., atmospheric pressure included. At a scale of 50lb. to the inch the height A B will then be 1·5in. The rectangle A B C D will then represent the volume and pressure of the steam during admission, or may represent one volume of a gas. We will assume that admission takes place during one-fourth of the stroke; the remainder of the stroke we divide into any number of parts which may be equal parts. In our diagram each part is taken as half A D. We will now suppose the volume is allowed to expand into a space equal to one volume and half, or to expand to line 1 1. Now, drawing the line A1, we cut the line C D at E, and by producing E E′ parallel to V′ V, we cut the line 1 1 at E′, and this is the second point in our hyperbolic expansion curve, C being the first point. Similarly, by drawing the lines A2 A3 A4 A5 A6, we cut the line C D at points F G H I J, and these points produced at F′ G′ H′ I′ J′ cut the lines 2 3 4 5 6 at points which are the succeeding points in our hyperbolic curve. It will be seen that when the original volume has been expanded into two volumes the pressure is halved; when expanded to three volumes the pressure is reduced to one-third, as will be found by measurement. The lines below the diagram show this at a glance. We adopted this method of constructing the hyperbolic curve in diagrams Figs. 36 and 38. By reference to these it will be seen that in Fig. 36, in which is an indicator diagram from a high pressure non-condensing engine, the pressure throughout the greater part of the stroke is maintained much above that assigned by the law of relation between volume and pressure, the hyperbolic curve being much below the actual curve, showing that a very large amount of steam is condensed in the early part of the stroke and re-evaporated during the latter part, or that the steam ports and clearance spaces were very large, so that a great volume of steam was necessary to fill these, this volume coming into play during the expansion part of the stroke and maintaining the pressure. In the diagram it will be seen that we had added about 4 per cent. for the volume of the steam filling these spaces, but it was probably very much more than this, 7 per cent. being a common quantity.

The properties of the hyperbolic curve enable us to assign a point in the stroke to which steam must be admitted to give the indicator curve of expansion, or rather a point to which steam would have to be admitted to give that curve if steam were not condensed in the early part of the stroke in unusual quantities. This point is given at K on the line B B′ of Figs. 36 and 38, and is found as follows:—A point in the indicator diagram is chosen at which the expansion curve has become steady, as at K on the line 4, 4, Fig. 36, or on the line N5 on Fig. 38. The line 4, 4 or N5 being extended to the absolute vacuum line, the line 4 B′, Fig. 36, or N N, Fig. 38, is drawn, and

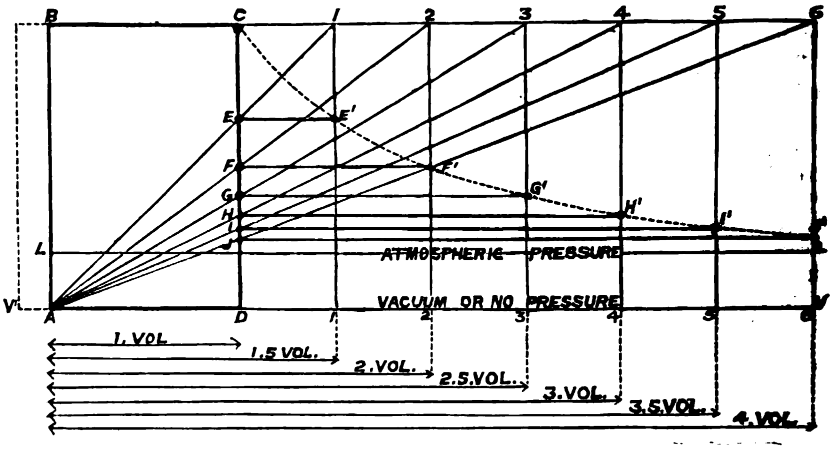

Fig. 40.

parallel thereto is drawn the line K K, starting from the point chosen in the indicator diagram curve. The point K on

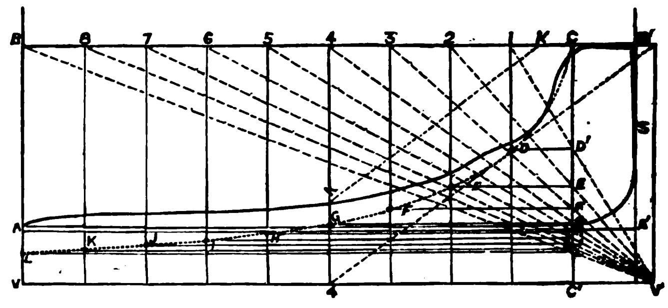

Fig. 36.

the admission line represents the point at which steam would have to be cut off to give the curve actually obtained, were it not

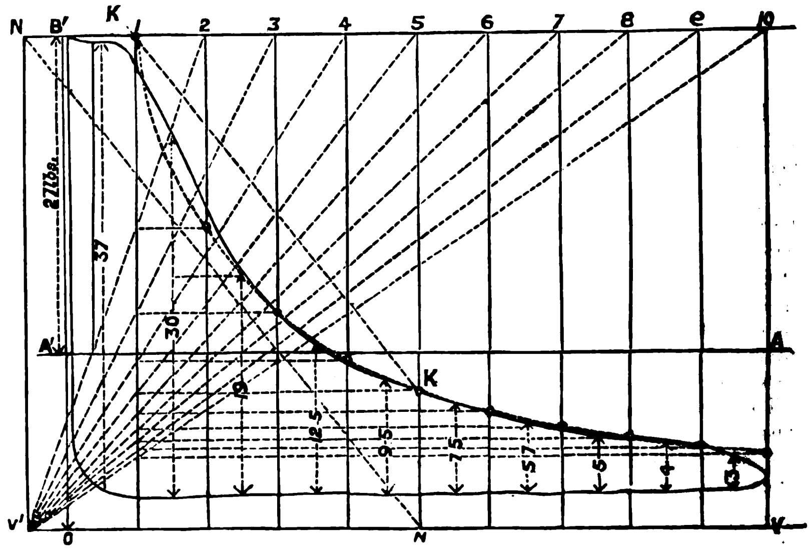

Fig. 38.

that initial condensation causes the admission of a quantity of steam which is afterwards re-evaporated at the lower pressures during expansion. The distance N, K represents, then, the volume of steam necessary to produce the curve the indicator has given.

Turning to Fig. 38, it will be seen that although the range of expansion was very large, the actual indicator diagram

* For Art. 11, see *The Electrician*, 4th December, 1885.

Digitized by Google

curve follows very nearly the theoretical curve drawn by allowing about 7 per cent. for steam used in filling ports and clearance spaces. The actual curve is rather higher at the commencement, and only a little lower at the latter end of the stroke than theory demands. The engine from which the diagram Fig. 38 was taken was working with a good steam jacket, while Fig. 36 was taken from a cylinder without a jacket, and from an engine using much higher initial pressure.

In further illustration of Boyle's law, we may take the simple diagram given at Fig. 41. Here A D E C represents the original volume. Now, suppose the volume doubled and the pressure correspondingly reduced to one half. We then get the rectangle, whose height is D′ E′ instead of D E, and E and E′ form two points in a hyperbolic curve. By again doubling the volume, we get a rectangle whose height is D″ E″, and the corner E of the rectangle forms the third point in the curve. By again doubling the volume, so that it fills a space A D‴, we get a rectangle whose height is D‴ B‴, and the corner B‴ forms the fourth point in the curve. By again doubling the volume the fifth point E and the curve may be indefinitely extended

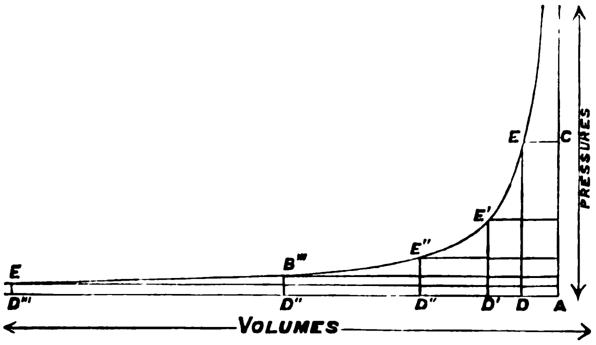

Fig. 41.

in this direction. On the other hand, if, instead of expanding from D E, we compress, say, double the pressure and half the volume, we get a point by which the curve may be indefinitely extended upward to represent compression instead of expansion.

A NEW APPARATUS FOR THE ESTIMATION OF COPPER.*

BY A. H. LOW.

The apparatus described was devised as the result of numerous experiments upon the electrolytic method of determining copper, with a view to obtaining a more rapid and certain method than that generally used. It consists essentially of a simple electrotyping apparatus, with a parchment-paper diaphragm, instead of the porous clay cylinder. The outer cell is a glass beaker, 1¾in. diameter, and 2½in. high, and the inner one a piece of thick glass tube of somewhat smaller diameter, open at the ends. The lower end is ground slightly conical, and the parchment paper diaphragm is stretched across it, and clamped tight by a conical silver ring fitting on the ground part. The upper end of the tube is stopped with a wooden plug bored through the centre to admit an amalgamated zinc rod which reaches nearly to the bottom, and there is also a groove in the side for the escape of gas. At the bottom of the beaker is placed a platinum electrode, consisting of a circular base plate as large as the beaker will admit, to which are united, by means of gold solder, several concentric cylindrical walls, about ½in. high. A strip of platinum, and a wire of the same metal attached to the outer wall, form the connection with the opposite electrode by means of a binding screw. The weight of the platinum electrode is about ¼oz. troy, and its surface on both sides is about twenty square inches. The tube is surrounded by a spring ring of sheet iron, with two horizontal arms attached, which support it on the top of the beaker, the level of the bottom being adjusted by sliding the tube in the ring.

The solution from which the copper is to be deposited must be always of about the same nature; slightly acid, with sulphuric acid, and contain about forty-five grains of chlorate of potash. The volume should be sufficient to fill the beaker to a depth of ¾in. When much iron is present in the substance under examination it should be previously removed, as it increases the electrical resistance. When the solution is prepared a mixture of sulphuric acid and water, in the proportion of 1 to 4, is poured into the inner tube to the depth of about 1in., the zinc rod is inserted and connected with the platinum electrode, and the tube is lowered until the diaphragm just touches the surface of the copper solution. The deposition of the metal begins at once, and is finished in from one to two hours, according to the amount of copper present. The weight of the sample operated on is in all cases 1 gram. If towards the end of the operation the solution becomes too warm, the beaker must be cooled by placing it in water to prevent the acid liquor attacking the deposited copper and re-dissolving it. The operation is completed when bubbles of gas are given off from the platinum electrode, and a drop of the solution no longer discolours sulphuretted hydrogen water. The tube and platinum electrode are then lifted together without disconnecting them, and the latter is immersed in a beaker of water, while the former is returned to its place. The electrical connection is then broken, and the electrode, after being washed first with water and then with alcohol, is dried and weighed. For further use the deposited copper is dissolved off the platinum by nitric acid. Before setting aside the tube it is well rinsed with water to remove the acid from the diaphragm, which will last for several operations. Examples of the application of the method to different copper ore and furnace products are given, and the results are practically identical with those obtained by electrifying with a battery current. The time occupied in the operation was one hour and a half in each case.

LITERATURE.

Lightning Conductors; their History, Nature, and Mode of Application. By Richard Anderson, F.C.S. Third Edition. [London: E. and F. N. Spon, 1885.]

In noticing the previous editions of this book it was stated that for historic information, for grasp of the whole subject, theoretically and practically, the work had no equal. All the praise that has been given to it is none too great, nor, indeed, would it be possible to estimate too highly the value of the book. The present edition "has been carefully revised," many chapters "have been rearranged and rewritten, and a considerable amount of new matter has been added." There is no doubt the author can justly claim that his work has "exercised a salutary influence in drawing public attention to the importance of the subject." The majority of accidents, so far as buildings at any rate are concerned, are, we feel sure, preventible; but, after all, it is comparatively few who trouble to obtain this protection. We believe that the periodic testing of lightning conductors is becoming more general, and this is important, for time in many ways degenerates the efficiency of the rod, so that what might when erected have been protective becomes a false and untrustworthy reed. Mr. Anderson has consistently advocated periodic testing, and has devised simple apparatus for the purpose, which is described in this work. Altogether the work is far in advance of any other publication on lightning conductors.

Electrical Saponification.—Prof. Rotondi has recently completed his experiments upon the application of electricity to the decomposition of concentrated salt solution into caustic soda and chlorine gas for commercial purposes. He has found that with a dynamo and diaphragms the process of saponification is easily effected by means of common salt and fat. The separation of the resultant products, glycerine, soap, and chlorine gas is a matter of no difficulty. No caustic soda is necessary for saponification.

SCIENCE AND POLITICS.

How hard it is to maintain an attitude of impartial indifference during periods of great national excitement has just been illustrated in two very dissimilar quarters. The Church has been provoked out of its cautious neutrality by an attack upon its privileges; and, for reasons not perhaps so intelligible, the hierarchs of science—or, at all events, some of the most prominent of their number—have proclaimed their distrust of one political party, and openly taken sides with the other. The *rôle* of a bystander is generally an ignoble one, and when he is a looker on perforce, a sort of captive over whose booty a couple of ruffians are quarrelling, the temptation to take sides with one or the other becomes irresistible. This, however, is not exactly the position of the scientist. The multitude, it is true, are not enamoured of science, and are sometimes hostile to its achievements; but they are almost powerless as obstructives, and, at least for the present, science is as free and as hopeful under one English ministry as under another. But scientists are human beings; and as one of them declared the other day that if he had had a vote he would have given it against the party he had always previously voted for, we may conclude that his more fortunate *confrères* who possessed votes disposed of them under similar human promptings They will regret this none the more for the peevish threat to disfranchise the learned communities because they have dared to vote like educated citizens and not as party men.

But another and quite novel reason has been put forward to induce or to justify the severance of the scientific spirit from its traditional leading. A letter, to which special prominence was given in the columns of *The Times* during the thick of the General Election, drew attention to the ethical aspects of the strife in such a startlingly original fashion that the newspapers have hardly yet left off talking about it. The writer claimed to be a representative of science; the pursuit of science is the pursuit of absolute truth; the spread of science is rapidly supplying the world with a higher standard of truth than has heretofore prevailed, and a more sensitive conscience as regards the baseness of lying and the grandeur of unflinching veracity. How disappointing, then, how disgusting, it was to witness our foremost politician employing the subtleties of his intellect to explain away obvious facts, and spread glosses over palatable lies! Such was the drift of this remarkable letter, the moral of which points plainly to the scientific excommunication of political sophists in general and to that of their super-subtle chief in particular. Science turns its back upon all such, carrying the "standard of truth" along with it.

More power to its arm, say we; but we are not quite persuaded of the unbiassed sincerity of the standard bearer, who, we suspect, would have been less severe on the sophistry if the conclusion had pleased him better. Nor are we so confident about the attractiveness of the standard itself; for, bitter as is the reflection, it is none the less a fact that the very qualities which the champion of science, of pure truth, condemns most, are what the multitude relish best. If science can counteract this bad taste by inculcating a devotion to truth in politics, such as is essential in the examination of natural phenomena, it will indeed accomplish a kind of moral revolution. A scientific habit of thought brought to bear upon political questions is greatly to be desired; but side by side with the progress of science, and its application to public affairs, the tendency latterly has been to cast it aside, to relegate it to the planet Jupiter, as an obstructive factor in the path of social advancement. And the explanation is not far to seek. The object, the sole object, of scientific research is to ascertain facts, to get to the bottom of everything where truth is to be found. This is the scientist's goal, on the road to which he meets with no conflicting interests or temptations, and at the end of which his reward is sure. If *The Times'* correspondent had been more of a scientist and less of a politician for the moment, he would have remembered that the very reverse of all this is true of a political career. We need not particularise. The facts are too conspicuous. Selfish interests dog the footsteps of the politician whichever way he turns, and even his noblest aspirations cannot be severed from his personal ambition to realise them. As to political truths, well, such as are useful for his ends are brought into prominence, whilst those that are inconvenient or inopportune are discreetly ignored. This economy in the matter of "truth" has even been justified by the example of the scientific teacher who refrains from overloading the minds of his humbler pupils, or who propounds a working theory, for convenience sake, which he knows to be scientifically unsound. The pupils of the political platform are very humble indeed. If our great men of science object to the superficiality and falsity of teaching which is the inevitable consequence of politics made popular, they had better say so plainly; only it is rather late in the day. Meanwhile, we repeat, the multitude prefer things made easy and pleasant.

Digitized by Google

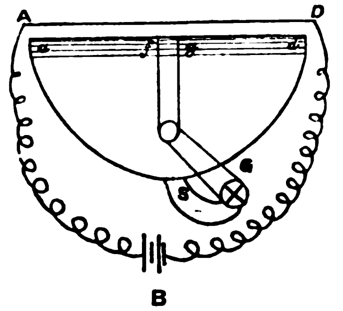
That the sophistry and apparent unscrupulousness complained of are due mainly to the character of the audience can be shown in a few words. First, it is a significant fact that, although the reproach is levelled at the head of one man, the defence has been taken up by his foes as well as by his friends. They all alike feel the partial truth of the accusation, and, without resenting it strongly, plead the exigencies of modern political life in extenuation. Secondly, it is notorious that he who is now described as the greatest culprit was himself but a few years ago a chief apostle of the verities; and it is well known that his enemies were dethroned because of their alleged unveracity. From these and other indications, therefore, we may infer that truthfulness is highly respected, if not always practised, in quarters the most suspected; and what the scientist has got to do is, not to raise the standard of truth, but to show how it can be followed with a tagrag and bobtail of ignorant self-seekers at your heels; or, better still, to teach us how the science of politics can be practised in these days without the help of this base following. Notwithstanding their many defects, common to all multitudes, there are reasons for asserting that the English populace resent a falsehood more fiercely than any other race of people. But it has to be found out; and however high their ideal of truth may become under the moral influence of either science or religion, the detection of falsehood is for men who can write letters to *The Times*, not for the average audience of a political spouter. Without knowledge and judgment a scientific love of truth will count for nothing; and seeing that we have deliberately taken the ill-informed and foolish into the national council, we have little right to be surprised that the art of political bamboozlery is attracting an increasing number of professors.

CORRESPONDENCE.

EXPERIMENT IN ELECTRIC INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Upon reading Mr. E. A. Williams's statements concerning electric induction in *The Electrician* for October 23rd, the following experiment suggested itself to me, which I think proves the correctness of our received theory in a very simple way. It gives an easy way to investigate the direction of the current in the part of the secondary circuit which is immediately under the inductive action of the primary current. The experiment may be familiar to others, but I have not seen it, and Mr. Williams says, in *The Electrician* for November 6th, that he is not aware of any investigation on this part of the circuit. I submit the experiment, and ask criticisms if it is not conclusive.



Let B A D be a primary circuit, with battery at B, and with arrangements to start, stop, and reverse the current at pleasure. Let *s a f o g d s* be the secondary circuit, with the part *a f g d* under the inductive action of the primary circuit A D. At *f g* is a short interruption, from which wires are brought down to *o*. A galvanometer, G, is arranged so as to be connected either with the wires at *o* or *s*. If with *o*, then the wires at *s* are joined together and the circuit is complete. If with *s* then the wires at *o* can be joined, and the circuit will be complete. Before closing the secondary circuit I closed the primary, and found that, despite all my precautions, the galvanometer needle was slightly affected by the currents, for I was alone, and had to bring the terminals near the galvanometer. The result was that the needle would swing *slowly* through about 4 scale divisions when the current was made, or broken, or reversed.

I now connected *s* with the galvanometer, and made the connections in such a way that by theory the effect of the secondary current would cause a deflection of the needle opposite to that of the primary current. When the primary circuit was closed the needle gave a sudden jump in direction indicated by theory, and then slowly swung back under influence of primary current. I opened the primary circuit, reversed it, &c., and all was in accord with theory. I now broke the circuit at *o*, leaving wires at *s* united with G, and now got no effect upon the galvanometer, showing that no current, or one too small to be detected, flowed from *a* to *d*, through *s*. I next joined the parts at *o* to G, so that the theoretical swing should be opposite to the swing caused by the primary, as above, and joined the parts at *s* directly.

I now closed the primary, and got a sudden jump of the needle in accord with theory, and next the slow swing due to the action of the primary current. Breaking the primary circuit, or reversing it, gave results in exact accord with our received theory. Opening the secondary circuit at *s*, I could get no effect upon the galvanometer. To sum it up, my experiment shows in a very clear manner, I think, that our received theory is correct. If Mr. Williams's theory about difference of electric potential between *a* and *d* were correct, there should be a greater current when the circuit is broken at *s* than when closed, for the whole flow of electricity due to this difference of potential should take place along *a d*, but I have shown that there is no flow, or else so small a flow as not to be indicated by my galvanometer.

On the whole I am inclined to think that our present theory is correct, and that his "cogent arguments" are not supported by facts.—Yours, &c., T. A. SMITH, Professor.

Beloit, Wis., U.S.A.

GAS PRESSURE ALARMS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the issue of *The Electrician* for October 9th last I find Mr. Tindall, of the Midland Association of Gas Managers, showed in action one of Bishop's electrical gas pressure alarms. I wish to say W. Valon, C.E., designed a similar apparatus for the gas works at Ramsgate about two years ago, and the work was carried out by me.

By inserting the above you will greatly oblige,—Yours, &c.,

W. COVINGTON,

Electrical Engineer to the Ramsgate Local Board.

8, Borough, Canterbury, Dec. 15, 1885.

SUBMARINE CABLES: EARTH CURRENTS.

BY A. E. BAINES.

When a submarine cable is tested with a view to the determination of its absolute insulation, or conduction resistance, or its electrostatic capacity, there are certain subsidiary phenomena to be considered and taken into account in order that correct results may be arrived at. Amongst the more important of these phenomena are the extraneous or *earth* currents which traverse the cable, both when one of its extremities is insulated or when both are connected, directly or indirectly, with the earth. When the cable is insulated at the far end of the line, and a test is being taken, at the near end, of the resistance which its gutta percha or india rubber covering offers to the passage of the current to the water which surrounds it, we require to observe the galvanometric deflections given through that

Digitized by Google

covering by our battery. If those deflections do not correctly represent the value of a known electromotive force (E) through an unknown resistance (x) we can have no accurate basis for calculation. That is to say, if E is variable, and we have not obtained the amount of its variation, we cannot determine x, for we do not know E. Now our battery, we will suppose, has an E.M.F. (E) which is constant, and the earth, for the time being, has another E.M.F. (E_1) which is not constant, and which may or may not be of the same sign (+ or −) as the battery current we are employing. It therefore becomes necessary to observe the sign, and to calculate the value of E_1 in order that we may acquaint ourselves with the degree of error it introduces into the test. As regards the origin of these extraneous currents very little is known. Every electrician has a theory of his own. In all probability they are due not to one, but to a multiplicity of causes. It will be better for us only to consider effects.

If two insulated wires whose ends are to earth be laid or erected parallel, and in closer proximity of distance to each than to any other conductor, and a current of electricity be sent from the battery E (Fig. 1) along either circuit, in the

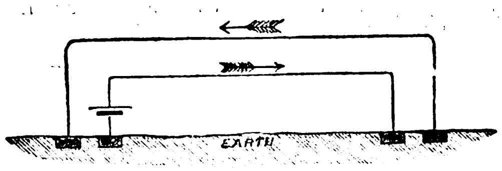


Fig. 1

direction indicated by the arrow, a second, sympathetic, current will, at the moment the circuit is closed, traverse the other line, but in the opposite direction. That is to say, if a copper or + *positive* current be sent along one line it will have the effect of *creating* a *negative* current in the other line, or *vice versâ*. This phenomenon is called *induction*, and the second responsive or sympathetic current is said to be *induced* by the action of the first.

The laws and principles of induced currents briefly stated are as follow:—The first impulse of the current in any conductor is to induce an *inverse* current in any other similar conductor which may be close to it; at the moment it ceases it produces a *direct* current. A current which *diminishes* in strength has also the latter effect, but one which *increases* in strength creates an *inverse* induced current. A *constant* and *continuous current, however, has no observable inductive properties.* From the above it will be seen that the induced current in any line depends upon the variation of another current for its creation. The current or currents flowing through the earth cannot be constant, but must, at equal or unequal periods, alter in strength, inducing in any neighbouring circuit *inverse* currents at each *increase*, and *direct* currents at each *decrease* of force. The E.M.F. of these extra currents is proportional to the E.M.F. of the primary currents.

Let us now take the case of a submarine cable, C, extending between two stations, A and B, a distance of, say, 1,000 knots. (Fig. 2.)

To all intents and purposes the earth is an electrical conductor through which currents of variable E.M.F. quantity and sign are always flowing. Moreover, it is an electrical conductor parallel to the cable circuit, which latter, although insulated at B, has a leak (due to the fact that nothing is an *absolute non-conductor*) through every inch of its gutta percha covering, or, in other words, from A to B. A variable current or currents of electricity proper to the earth, generated in the earth, no matter by what agency, and traversing the earth from A to B, will *induce* a current or succession of currents in the cable from B to A, or the reverse. The cable current in this case is therefore induced, will vary in strength or E.M F. and sign with the earth current proper, and as may be conceived will either militate against or increase the apparent strength of any battery current we may require to put into the cable. The deflections given by the battery (E) will, in point of fact, calling the induced current E_1, be $E+E_1$ or $E-E_1$. In both instances we require to eliminate the value of E_1 from our test, and this can be done in the manner shown in Fig. 2.

A little experience will enable the operator to detect and eliminate the values of the earth induced currents in divisions of the scale from the deflections $d \times \left(\frac{G+s}{s}\right)$—where d is the cable reading in divisions, G the resistance of the galvanometer in ohms, and s that of the shunt in ohms—obtained with the cable and battery. For instance, if E_1 were found to vary between 50 and 100 + while it was wished to use a − battery current (or zinc to line) for testing, it would be sufficient for all practical purposes to subtract a mean of $75 \times \frac{G+s}{s}$ from the *full* cable readings. Subtraction in this case because a + current coming from the line is equivalent to a − one passing into it. If the signs are the *same* the extra deflection due to E_1 must be *added*.

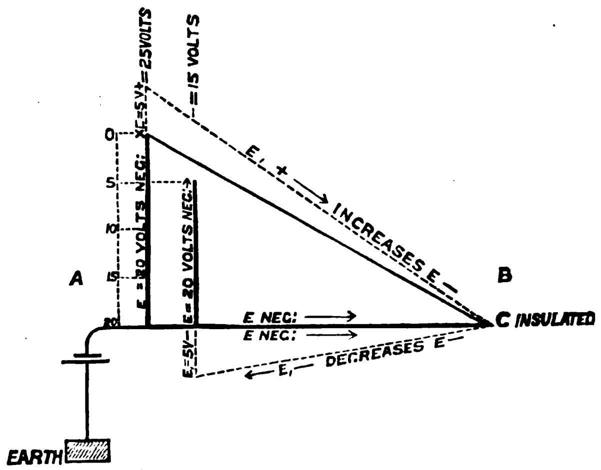

Fig. 2.

In the above example the mean of E_1 (5 volts) is supposed to be constant; E is negative. The thick vertical line to the left represents the *true* strength of E, and plus the dotted line above it shows the *apparent* strength, or $E+E_1$; that is if E_1 be of positive sign. The thick vertical line to the right shows the apparent diminution of E due to E_1 being also negative (or of the same sign as E), as shown by the dotted line below it. In the first case the result is an apparent decrease of R, while in the second R appears to be higher than it really is, for the reason that deflection and resistance are in the inverse ratio.

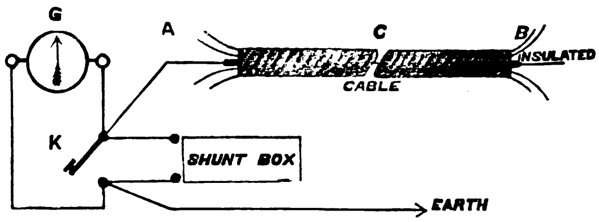

Fig. 3.

Practical connections at Station A preliminary to insulation test. Use same shunt as that during electrification of cable, if possible, to simplify calculation; if not, use any convenient shunt. With K open take readings of induced current flowing from cable until its strength and nature are understood.

Let d = deflection with cable and battery, E, (negative current) = 250 divs.

„ d_1 = mean deflection with cable and earth current E_1 (positive current) = 75 divs.

„ G = 6000 ohms (galvanometer resistance).

„ s = 1000 ohms (shunt resistance).

Then $d \times \left(\frac{G+s}{s}\right) - d_1 \times \left(\frac{G+s}{s}\right)$ = true deflection with cable and battery.

Substituting values we get $\frac{6000+1000}{1000} = \frac{G+s}{s} = 7$, and $250 \times 7 = 1750$ = observed d.

$d_1 \times \frac{G+s}{s} = 75 \times 7 = 525.$

Digitized by Google

Then $1750 - 525 = 1225$ = true d or true deflection given by known E.M.F through x.

It is better to eliminate the exact number of divisions due to E_1 at each 15 seconds or minute of electrification of the cable instead of taking an approximate mean, but such a course requires experience. Indeed, in practice, E_1 is but seldom considered in insulation tests, the mean of five minutes each of zinc and copper readings being taken as correct. This is objectionable, in that it supposes the sign of E_1 to remain constant for ten minutes, a thing that very seldom happens. It is safer to observe E_1 before applying zinc to line, and again after Z has been discharged to earth, and before copper to line is applied. In this way you get a more exact knowledge of the variability of E_1.

We will now proceed to observe what takes place when *both* extremities of the cable are put to earth; direct in one case, and through a galvanometer in the other. Here a somewhat different phenomenon is noticeable. An earth current flows in the cable, but it is no longer a simple earth-induced current; it is probably due to a difference of electrical potential or pressure at the points A and B, and may traverse the line from either of those points to the other. A variety of causes may also contribute to the origin of this extra current. In copper resistance tests it gives infinite trouble to the electrician, who has to follow it in all its variations, and make allowance for its effect. Its value is easily calculated.

Let R = resistance of copper conductor of cable.
„ r = „ „ shunt used while observing E_1.
„ R_1 = high resistance coils in circuit for constant of galvanometer.
„ D = deflection for constant of galvanometer.
„ d_1 = „ given by E_1.
„ E = E.M.F. of testing battery in volts.
„ M = multiplying power of constant shunt $= \frac{G+s}{s}$ (1).
„ m = „ „ „ shunt used for $E_1 = \frac{G+s}{s}$ (2).

Then if E_1 is smaller than E,

$$E_1 = \frac{(R+r)\,m\,d_1\,E}{R_1 M D} \quad . \quad . \quad . \quad . \quad . \quad . \text{ volts.}$$

Example. With a battery of 20 volts, a galvanometer of 6,000ω resistance, and a shunt of 50ω resistance we have obtained a deflection, D, through 100,000ω (R_1) of 500 divisions.

$$M \therefore = \frac{6000+50}{50} = 121,$$

and $500 \times 121 \times 100{,}000 = 6{,}050{,}000{,}000 = R_1\,M\,D$.

Substituting the cable (R) for R_1, the shunt remaining unaltered, we get a deflection d_1 of 75 divisions through a cable resistance of 10,000ω (R) and shunt 50ω (r); m is also = 121 in this case.

$\therefore 75 \times 121 \times 10000 + 50 \times 20$ volts $= 1{,}824{,}075{,}000 = (R+r)\,m\,d_1\,E$

and $\frac{1{,}824{,}075{,}000}{6{,}050{,}000{,}000} = {\cdot}3015$ volt $= E_1$.

For this example I have taken what may be thought in such a long cable an exceptionally low value for E_1. I have found the simple earth current to vary between a fraction of a volt and 5 volts, seldom more. The induced E_1, however, in cables laid N. and S. not unfrequently exceeds 15 or 20 volts.

MINIMUM E.M.F. IN TRANSMITTING POWER.

Our New York namesake gives the following article by Prof. H. S. Carhart:—

The prominence attained by recent practical experiments in the electrical transport of power justifies the fullest theoretical discussion. Any light that theory can throw upon the subject must be of some value. I shall therefore attempt to make clear the question of minimum E.M.F. that can be employed under the defined conditions, even at the risk of being too mathematical for some readers.

So far as observed the discussions of the general problem have proceeded upon the following basis:—Given the E.M.F. of the generator and the resistance in circuit, to find the *maximum* rate of working or the maximum work that the motor can do. What I propose is, given the resistance in circuit and the work required of the motor, to find the *minimum* E.M.F. This latter is the form in which the matter presents itself as a practical problem. I shall first give the usual solutions corresponding to the former conditions, and then the new solutions with the latter defined ones. In each case R and C denote resistance and current strength, E and E_1 the direct and counter E.M.F. of generator and motor respectively, and W the work done by the motor per second.

1. Given E and R to find C and *maximum* W.

a. Algebraic solution. The total energy of the current is divided into two parts, one of which goes to heat the conductor, and the other is absorbed by the motor and converted into useful work. Hence

$$C E = C^2 R + W \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The solution of this equation of the second degree is

$$C = \frac{E \times \sqrt{E^2 - 4RW}}{2R}$$

Plainly $4RW$ cannot exceed E^2, or C would have an "imaginary" value, which is impossible. W will therefore be a maximum when $4RW = E^2$. Hence,

$$W = \frac{E^2}{4R} \text{ and } C = \frac{1}{2}\frac{E}{R}$$

The current for maximum work is therefore reduced to half the value it would have with the motor at rest, and $E_1 = \frac{1}{2}E$. This is known as Jacobi's law. It is not the law of efficiency but of maximum activity.

In the above values W and C are expressed in given terms; and we have the further deduction that for maximum rate of working the counter E.M.F. of the motor equals half the direct E.M.F. of the generator.

b. Solution by the calculus. By transposition of . . (1)

$$W = C E - C^2 R \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Whence $\frac{dW}{dC} = E - 2CR = 0$ for the *maximum* value of W, since the second differential is negative. Therefore

$$E = 2CR \text{ and } C = \frac{1}{2}\frac{E}{R} \text{ as before.}$$

The value of W may be found by substituting the value of C in (2).

2. Given W and R to find C and *minimum* E.

a. Algebraic solution. The work done by the motor is

$$C E_1 = \frac{E_1(E - E_1)}{R} = W \quad . \quad . \quad . \quad . \quad . \quad (3)$$

If W and R are constants, then is $E_1(E - E_1)$ a constant also. Now, when the product of two terms is a constant their sum is a minimum when they are equal to each other. But the sum of E_1 and $E - E_1$ is E, the E.M.F. of the generator. Hence E is a minimum when E_1 equals $E - E_1$; or $E_1 = \frac{1}{2}E$. This condition corresponds to Jacobi's law, as might have been inferred directly, because the conditions determining maximum rate of working with a given E.M.F must also define the minimum E.M.F. required to do a given amount of work.

To determine E and C in terms of W and R, substitute for E_1 in (3) its value $\frac{1}{2}$ E, and we have

$$E^2 = 4RW, \text{ or } E = 2\sqrt{RW}.$$

Whence $$C = \frac{1}{2}\frac{E}{R} = \sqrt{\frac{RW}{R^2}} = \sqrt{\frac{W}{R}}$$

b. Solution by the calculus. From equation (1)

$$E = CR + \frac{W}{C} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Digitized by Google

Whence $\frac{dE}{dC} = R - \frac{W}{C^2} = 0$ for *minimum* value of E, since in this case the second differential coefficient is positive. Hence,

$$R = \frac{W}{C^2} \text{ and } C = \sqrt{\frac{W}{R}} \text{ as before.}$$

Substituting the value of C in (4) and

$$E = 2\sqrt{RW}$$

Also $$CE_1 = W \therefore E_1 = \frac{W}{C} = \sqrt{RW}$$

Therefore $E_1 = \frac{1}{2}E$ as above.

It appears, therefore, that the E.M.F. varies as the square root of the resistance. Hence, if any reduction of E.M.F. is attempted by reducing the resistance, the reduction of the latter must be much more rapid than the former. If R is reduced to one-fourth, the E.M F. is reduced only to one-half. But the resistance may be increased fourfold by merely doubling the E M.F., the same amount of work being done with the same efficiency. Whenever attempts are made to work with low E.M.F. as considerations of safety demand, then difficulties at once present themselves. The above discussion shows that with the requirement of a given amount of work to be done by the motor, the E.M.F. has a minimum value which cannot be reduced except by an inordinate and impracticable reduction of resistance.

To apply the results to a concrete example. Assume twenty locomotives on a New York elevated road to represent 2,200 horse-power. If the electric motors replacing them have an intrinsic efficiency of 90 per cent. in round numbers 1,800,000 watts of energy must be supplied to the motors per second. If the resistance in circuit is 0·072 ohm, then

$$E = 2\sqrt{RW} = 2\sqrt{1,800,000 \times 0\cdot072} = 720$$

and

$$C = \sqrt{\frac{W}{R}} = 5,000$$

With an assumed resistance of about three-quarters of an ohm the minimum E.M.F. required to transmit to the motors 2,200 horse-power is 720 volts, and the current is 5,000 amperes.

THE SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.

The annual meeting of this Society was held at the Institute of Civil Engineers, on Thursday evening, 10th inst., when, previous to the usual business, the report for the past year was read, and the officers for the ensuing year were elected. The report, after referring to the losses the Society had sustained in the deaths of Mr. Davey, Prof. Fleeming Jenkin, and others, announced that the Society's premium had this year been awarded to Prof. O. Lodge for his paper on the "Seat of the Electromotive Force in the Daniell Cell;" the Paris premium was given to Mr. W. H. Snell for his paper on the "Distribution of Electricity," whilst to Captain Sankey for his contribution on "Electrotyping with a Dynamo" had been assigned the Fahie prize. Steps had been taken by the Society to forward the object of a uniform and simplified electrical nomenclature advocated by Prof. Jamieson in the early part of the year, and the co-operation not only of the chief professors at English Universities, but of M. Hospitalier, and other leading electricians in Paris, had already been secured. A sub-committee was formed and now had the matter in hand. Mention was made of the formal Resolution of the Society forwarded to the Board of Trade with reference to the objectionable and impolitic clauses of the Electric Lighting Act; and hopes were entertained that some legislative action might shortly be taken so that the law would no longer obstruct, but rather help forward, the work of Electric Lighting. Dr. Fleming's suggestion recently laid before the Society for the creation of an electrical standardising institution was now receiving the careful consideration of the Council. The visit of the members to Swindon at the invitation of the president, Mr. Spagnoletti, was referred to in appropriate terms, after which the highly satisfactory financial condition of the Society was briefly set forth; and after a reference to the alteration made in this year's ballotting forms whereby twice the number of names required were submitted for selection, the report concluded with the Librarian's statement of the progress made by the Society's reading room and library during the past year.

A vote of thanks to the Council of the Institute of C.E. for the continued loan of their Lecture Hall was then proposed by Prof. Perry and carried unanimously. Votes of thanks were also accorded to the Foreign Secretaries of the Society, to the Hon. Treasurer, Mr. E. Graves, to the Auditors, and to the Hon. Solicitor, Mr. Bristow.

While the scrutineers were examining the balloting papers, a task which on this occasion occupied fully an hour and a half, Mr. WALTER J. MURPHY, assistant electrician of the telegraph ss. "Great Northern," read a paper describing, or rather suggesting, a method of eliminating the effects of earth and polarisation currents in fault testing; after which the Secretary read a paper by Mr. H. KINGSFORD, Associate, also relating to cable testing. The latter paper we print at length below. Mr. Murphy drew attention to the several defects of Mance's method, chiefly due to the variation of the testing current, and described an instrument designed by himself to obviate these defects. Mr. Murphy's suggestion, however, was not favourably received by the experts present, who, forming their judgment upon the diagrammatic testing method exhibited by the author, were of opinion that it would not do what was claimed for it. Mr. KINGSFORD's paper is as follows:—

A Method of Localising a Fault in a Cable by Tests from One End Only.

In experimenting some years ago to discover a trustworthy method of localising a partial fault in the case of a laid cable where no return wire was available, unsatisfactory results were nearly always obtained from the application of "Blavier's" tests pure and simple. I was then led to investigate for the first time a formula which until then had never interested me; total severances of the cable, or faults when both ends were available, having so far been the only defects which had occupied my attention. It needed, of course, but little consideration to trace the source of error, as testing to breaks had assured me of the well-known fact that the resistance of an end varies (as a rule considerably) in some ratio to the current through it, decreasing, with increased electromotive force, until a minimum resistance has been obtained. A partial earth would, of course, be effected in the same way by the so-called "polarisation." To obviate the error due to this fact I devised a method which I shall presently state, and an account of which I have long intended to publish. It is most probable that I should have delayed longer, being anxious to publish at the same time other matter which I have not yet had time to work into shape; but I was reminded of my intention by reading a very interesting article by Messrs. J. Anderson and A. E. Kennelly, in *The Electrician* of July 17th, 1885. These gentlemen recognise the source of error which I mention as accompanying the simple "Blavier," and suggest for its elimination a test the main principle of which is the same as that which characterises my own modification of that method. For reasons, however, which will, I think, be considered by most electricians as sufficient, I can but think that my method may in some cases be preferable. That of Messrs. Anderson and Kennelly requires an observer, battery, and a set of instruments at each end of the cable—a mode of testing which would be apt at times, I consider, to involve some little anxiety at least on the part of the responsible person. My method requires tests from one end only, and is as follows:—

In order that the current through the fault may be the same when the distant end is free as when it is to earth, proceed thus: First, take ordinary "Blavier," approximate distance of fault, and let that approximation from testing station $= x$ in ohms; from that we obtain approximate resistance from the fault to the distant end $- y$ ohms $-$, and approximate resistance of fault $- z$ ohms $-$. With these data we go to work to obtain an approximation to the resistance which must be inserted at the home end of the line when testing cable free at distant end. Should the test be taken on shore, there is perhaps no better method to adopt than that known as reproduced deflection. Using this method,

Let r = resistance of battery;

,, r' = resistance of well-shunted galvanometer, or $\frac{gs}{g+s}$

,, a = E.M.F. of battery.

Then $\frac{a}{r+r'+x+z} = \frac{a}{f}$ = current through fault when line is free at distant end;

and $\frac{a}{r+r'+x+\frac{yz}{y+z}} = \frac{a}{g}$ = current through x when line is to earth at distant end.

Portion of $\frac{a}{g}$ flowing through fau't = roughly $\frac{\frac{a\,y}{g}}{y=z}$

Digitized by Google

Let this quantity $= \frac{a}{h}$, then $h - f$ will represent the first approximation for resistance to insert, in ohms, or R_1.

Then, placing R_1 in circuit, we now take another observation with the line free at distant end, and then test again from the actual end of cable, with the distant end to earth. Thus, in the same manner as we procured x, y, z, and R_1, we obtain x_1, y_1, z_1, and R_2, and so on until we find that $R_n = R_{n-1}$. Results obtained with this insertion will be correct if the test be carefully taken.

On board ship I prefer to use a Wheatstone bridge, and shall consider a case in which an even bridge in employed. Should it be deemed advisable to use a dividing bridge, the necessary slight alteration in formula will, of course, suggest itself.

We first take simple "Blavier" as before, and obtain from the same approximations x, y, and z.

Let a = E.M.F. of battery ;
,, r = resistance of battery ;
,, r'' = ,, in either side of bridge ;
,, R, R_a, R_b, &c. = resistance unplugged when equilibrium is obtained with distant end free ;
,, R', R'^a, R'^b, &c. = resistance unplugged when equilibrium is obtained with distant end to earth ;
,, R_1, R_2, R_3, &c. = first, second, third, &c., approximations in ohms to resistance which must be inserted when testing line free at distant end, R_n being correct insertion.

Then, when distant end is free,

$$\frac{a}{r + \frac{r'' + R}{2}} = \frac{a}{c} = \text{current through fault ;}$$

and when distant end is to earth

$$\frac{a}{r + \frac{r'' + R'}{2}} = \frac{a}{d} = \text{current through "}x\text{."}$$

In the same manner as before we now find quantity of $\frac{a}{d}$ flowing through fault. Let this quantity $= \frac{a}{e}$, then R_1 will equal $2\,(e - c)$.

Having now obtained R_1 we proceed as before to obtain x', y', z', always testing, of course, from the actual end of cable when distant end is to earth. We must proceed until insertion represented by R_n = that represented by R_{n-1}.

I may hint with possible advantage to some readers that it is an excellent plan to make up a Wheatstone bridge of cable when practicable, especially in cases when the resistance to the fault is small, and when the fault is of such a nature as to require the application of a powerful electromotive force. In cases where the fault is considerably nearer to one end, tests should be taken from that end if possible. In the case of a high resistance fault near the distant end of the line, R_1, R_2, &c., might at times be so high as to seriously interfere with the sensitiveness of the test ; in such cases the E.M.F. must be altered. Should we find that additional inserted resistance makes no difference in result, we shall be safe, of course, in accepting such result as correct. As in every instance in which I have employed this method it has given me great satisfaction, I now publish it in the hope that others may find it as useful to them as it has proved to me.

Shortly after 10 o'clock the result of the balloting for members' and associates' representatives on the Council was announced, when the following gentlemen were declared to be elected :—

President : Prof. D. E. Hughes, F.R.S.

Vice-Presidents : Sir Charles Bright, M.Inst.C.E. ; Edward Graves ; Colonel Sir Francis Bolton, J. Hopkinson, M.A., D.Sc., F.R.S.

Ordinary Members of Council : William T. Ansell, F.R.G.S. ; Prof. W. E. Ayrton, F.R.S. ; E. B. Bright, M.Inst.C.E. ; R. E. Crompton, M.Inst.C.E. ; William Crookes, F.R.S. ; Prof. George Forbes, M.A., F.R.S.E. ; Alexander Siemens, Augustus Stroh, Captain Philip Cardew, R.E. ; J. A. Fleming, M.A., D.Sc. ; Prof, John Perry, F.R.S. ; Prof. Silvanus P. Thompson, B.A., D.Sc., F.R.A.S.

Associate Members of Council : W. Lant Carpenter, B.A., B.Sc.; Gisbert Kapp, John Munro.

Honorary Treasurer : Edward Graves.

Honorary Secretary : Colonel Sir Francis Bolton.

Auditors : J. Wagstaff Blundell (Wagstaff Blundell and Co., chartered accountants, 12, Delahay-street, Westminster); Frederick C. Danvers, India Office, S.W.

Honorary Solicitors : Messrs. Wilson, Bristows, and Carpmael, 1, Copthall-buildings, E.C.

LIGHTHOUSE ILLUMINANTS.—ELECTRIC LIGHT APPARATUS.

REPORT OF PROF. W. GRYLLS ADAMS, F.R.S., &c.

(Continued from page 98.)

Photometric Observations in Hut 2.

The photometric observations in hut 2 were made by means of the achromatic lens of 7·593 ft. focal length, and the Bunsen photometer, the light concentrated by the lens being compared with the light from the Douglass standard lamp. The Douglass standard was a large colza oil lamp with a slit used as a Methven slit, and which could be made of any convenient size, according to the brightness of the light to be compared with it. This Douglass standard, as used on November 8th and November 10th, in No. 2 hut, was compared with the pentane gas flame on the morning of November 10th in the photometric gallery, and the result of a long series of comparisons gave the light of the Douglass lamp as 3·166 candles.

The pentane flame and the Douglass standard were compared directly by means of the Bunsen disc or the star disc without any absorbing medium.

Ruby glass and a solution of ammonia sulphate of copper placed before the eye were also employed, so as to compare the intensities of red and blue light in the two sources of light.

The readings as taken for red or blue differed by less than ·57 per cent., showing that these sources gave light nearly of the same quality or colour, and so may be properly compared for illuminating power without employing any medium in front of the eye to enable the observer to judge when he has equal illumination on the two sides of the disc.

On the evening of November 8th, 1884, the achromatic lens was arranged in hut 2. so as to compare the lights from the towers with the Douglass standard lamp.

Two sets of experiments were made :—

(1.) The lens was fixed as at A in Fig. 4. The star disc fixed at B, a distance of 3·38 ft. from A. The focal length of the lens 7·593 ft. C is the focus of the lens. The Douglass standard D was moved to and fro until a balance of light on the disc was obtained.

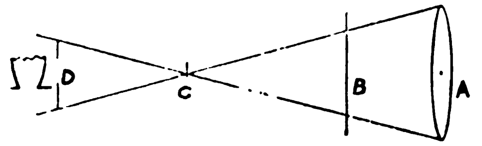

Fig. 4.

The points of disappearance of the star on the two sides were noted, and the mean of these points was taken as the position corresponding to the equality of the lights.

Ruby glass was used in front of the eye of the observer when measuring the electric light.

Hence, in these values the more refrangible rays, which are so abundant in the electric light, making it so much whiter than gas or oil, are neglected.

Measurements were made of the illumination from the single six-wick oil light with the Mew Island lens. The mean of the results obtained for the illumination at the focus was ·02337 candle, so that the illumination at hut 2 was ·000573 candle. This illumination would be given at hut 2 by a naked light of 22,030 candles placed on the lighthouse tower if there were no absorption by the atmosphere. The intensity of the naked light which, radiating in all directions from the lighthouse tower, would give the illumination measured at hut 2, is in each case given in brackets thus (22,030). The disc was then removed 2 ft. 6 in. nearer to the focus, so that it was at a distance of 1·71 ft from the focus. The measurements now gave an illumination of ·0227 candle at the focus, or ·000557 at hut 2 (21,410). Measurements were then made of the Wigham single 108-jet gas burner with the disc in the same position, when the illumination at the focus was found to be ·0235 candle, which gives an illumination of ·000576 at hut 2 (22,140).

Evening of November 10th. The observations of the electric current were made by the electro-dynamometer in the engine room, and the electromotive force was measured both between the terminals of the machines in the engine room and between the extremities of the arc in the "A" tower by means of two Cardew voltmeters.

The lamp employed was a new De Meritens lamp, which was used for the fisrt time. It was placed on the lowest stage in the "A" tower, and the lens employed was the cylindrical lens with vertical prisms. Observations on the illuminating power were made by me during the latter part of the evening in No. 2 hut, the current and electromotive force being measured during the same period by two of my students, one in the engine room, the other in the "A" tower.

Throughout the evening (the observations extended over about 2½ hours) the current and the electromotive force remained remarkably steady, for out of more than 50 observations of the current, there is no single observation below 112 amperes or above 125 amperes, and usually a slight increase of current is accompanied by a slight diminution of electromotive force, such as might be expected from a very slight change in the length of the arc.

The average number, obtained by multiplying the average E.M.F. by the

Digitized by Google

average current, gave 5,760 watts as the work expended per second in the external circuit, and 3,480 watts expended in the arc, the difference, viz., 2,280 watts, being expended in overcoming the resistance of the leads to the "A" tower. The E.M.F. between the extremeties of the arc was 29 volts, and between the terminals of the machines 48 volts.

On the evening of November 10th, 1884, a new De Meritens lamp was tried in the lower stage of the "A" tower with the cylindrical lens with the vertical prisms, and observations of the intensity of the light were made in No. 2 hut. The E.M.F. at the extremities of the arc was 29 volts, and the average current 120 amperes.

On this evening, when the new lamp was being tried in the "A" tower with the cylindrical lens and vertical prisms, I made measurements of the illumination given at hut 2 by the following method :—

The achromatic lens A (Fig. 4) was fixed in position, and the Douglass standard D was fixed at a distance of 7·96 ft. beyond the focus of the lens. The photometer disc B was moved to and fro on the stand between the focus C and the Douglass lamp.

This arrangement was more satisfactory than the arrangement of November 8th, and a very consistent set of measurements was obtained.

The mean value of the readings gave 5·5 ft. and 2·46 ft. as the distances of the disc from the Douglass standard, and from the focus of the achromatic lens respectively. Hence the illumination at the focus equalled ·633 candle, and the illumination at hut 2 was ·0155 candle (595,800).

At another period of the evening, the Bunsen disc was fixed at a distance of 3·38 ft. from the lens, as in the experiments on November 8th, and the Douglass standard was moved to and fro to balance the illumination on the disc. The measurements were now higher and the illumination was 1·933 candle at the focus, or ·0474 candle at hut 2 (1,823,000).

On the evening of December 17th, I made experiments on the three machines supplying current to the "A" tower, whilst Mr. Dixon was measuring the illumination given through the cylindrical lens with vertical prisms in No. 1 hut.

With one machine, from 7:30 to 8:30, the electromotive force at the terminals of the machine was 51 volts, and the average current was 133 amperes, giving about 6,750 watts at 600 revolutions.

With two machines to one arc, using the 40 mm. Berlin core carbons, the E.M.F. was 60 volts, and the current 172 amperes, giving 10,330 watts.

The illumination at hut 1 from one arc with the current from two machines in parallel circuit varied from about $\frac{1}{4}$th of a candle to $\frac{1}{6}$th of a candle from 8:45 to 9 p.m. (770,300 to 1,155,000), and amounted to $\frac{1}{3}$rd of a candle about 9:30 p.m. The two machines were then joined in series to supply two arcs in series in the "A" tower, when the E.M.F. was 82 volts and the current 158·4 amperes, giving 13,000 watts in the circuit; and the light from the two arcs gave an illumination in No. 1 hut of from $\frac{1}{3}$rd to $\frac{4}{10}$ths of a candle (1,540,000 to 1,849,000).

From 10 to 10:15 p.m., the three machines were driven, and supplied one arc in the "A" tower, giving an E.M.F. of 65 volts and a current of 160 amperes, *i.e.*, the three give no greater current through a single arc in "A" tower than the two machines in tension through two arcs in series.

Now, on throwing the belt off the third machine and driving that as a motor by means of the current from the other two machines, the E.M.F. remains nearly the same, 65 volts, but the current increases to 170 amperes, and the steadiness of working of the machines is increased. This entirely confirmes the experiments of November 10th, when two machines driving the third as a motor were found to do more work in the arc, and to produce more light, than the two machines alone, or than the three machines when all were separately driven by the engine.

From 10:30 to 11:30 p.m. experiments were made to see what was the amount of loss by the leads when using three machines together and with both De Meritens 81 square carbons and the Siemens 40 mm. Berlin core carbons.

(1.) With the De Meritens carbons and with the third machine as a motor, of the 66 volts no less that 30·4 volts are lost on the leads, and only 35·6 volts are useful in the arc, *i.e.*, $46\frac{2}{3}$ per cent. of the energy given out by the machines is lost on the leads. With the three machines, all driven direct by the engine, of the 65 volts in the circuit, 29·5 volts are spent in the leads and 35·5 volts on the single arc, or 45·4 per cent. of the energy produced is spent on the leads.

(2.) With the 40 mm. Berlin core carbons, it was found that with the same E.M.F. the current was greater than with the De Meritens 81 square carbons, being 175 amperes as against 162 amperes.

Also with the Berlin core carbons, when the third machine was driven as a motor by the current from the other machines, the current was increased from 175 amperes to 188 amperes. This is the largest current which, I believe, has ever been supplied to the "A" tower.

Thus it appears that of the energy which might be produced from two machines, only one-fourth, or 25 per cent, has been actually produced in the "A" tower by any arrangement of the machines, and that with present arrangements it is impossible to obtain more than this.

On the evening of December 18th, the separate machines and two machines parallel and two machines in tension were again tried, as on the evening of December 17th, and Mr. Dixon was measuring the illuminating power of the light.

The results quite confirm the observations of December 17th.

Two single machines L No. 1 and L No. 2 were tried separately, when it appeared that at the same electromotive force, 52 volts, L No. 1 gave a current of 136·7 amperes and L No. 2 gave a current of 131·4 amperes.

These machines were then joined in parallel circuit to supply a single arc in the "A" tower, and gave an E.M.F. of 64 volts and 171 amperes, a little higher E.M.F. than on the previous evening, and the illuminating power was also somewhat higher, going up to ·435 candle, and even to nearly $\frac{5}{10}$ths of a candle, the distance of No. 1 hut being 2,150 feet from the towers (2,010,000 to 2,773,000).

The machines were then joined in series to supply two arcs (biform) in series, when the electromotive force was 85 volts and the current 102·4 amperes, as compared with 82 volts and 158·4 amperes on the previous evening.

Experiments of January 23rd, and Observations of Illumination at Hut 2.

The method which I had adopted on November 10th was employed in hut 2 by Mr. Dixon to determine the illuminating power of the various lights, whilst I measured the E.M.F. and current in the engine room.

The Douglass lamp was fixed, and the star disc was moved to and fro, between the focus of the lens and the Douglass standard.

The lens employed at first in the "A" tower was the cylindrical belt with vertical prisms.

The Douglass standard was measured by me next morning in the photometric gallery, and found to be ·535 candle; and about two hours afterwards was again measured by Mr. Dixon, and found to be ·535 candle.

As the evening was hazy, and the haze was not uniform throughout the evening, only those observations which were taken about the same time are comparable with one another.

With the two machines supplying a current of electricity to a single arc in the "A" tower, the electromotive force was 60 volts and the current 186·7 amperes, giving 11,200 watts. The illumination at the focus of the lens in hut 2 was ·3617 candle and the illumination at the distance of hut 2 was ·00887 candle (341,000).

In the second set of experiments with two machines, the electromotive force was 61 volts and the current 175 amperes, giving 10,675 watts; and the illumination at focus of the lens in hut 2 was 2358 candle, giving an illumination of ·005784 candles at hut 2 (222,300).

With a single machine supplying current to one arc in the "A" tower, the electromotive force was 50 volts and the current 146·3 amperes, giving 7,315 watts, and the intensity of illumination at the focus was ·1531 candle, giving ·004024 candle at distance 6,200 feet (154,600).

The light from one arc supplied by one machine with the Mew Island lens was also measured in No. 2 hut. The average E.M.F. was 51 volts, and the current 144 amperes, *i.e.*, very nearly the same as before; and the illumination at the focus was 3·646 candles or ·0894 candle at hut 2 (3,437,000).

On comparing this light with the Wigham 108-jet gas it was found that during the early part of the evening the single 108-jet gas gave an illumination at the focus of ·01172 candle (11,050); that later on it gave an illumination of ·009036 candle (8,517) at the focus of the lens, and the Wigham quadriform (108 jet) gas gave an illumination of ·03583 candle (33,780).

Hence it appears that on a hazy night the single electric light with the cylindrical lens and vertical prisms gave an illumination equal to 14 times the Wigham 108-jet gas with the Mew Island lens.

On February 27th and 28th, and again on March 6th and 7th, experiments were tried and measurements made with the electric light placed nearer to the M.I. lens by 2 inches, 4 inches, and 8 inches than the focal length of the lens in order to measure the intensity of ex-focal light.

Comparison was made once or twice during the evening with the illumination given by cylindrical lens with vertical prisms or V.P., in order to compare with what the illumination would be when the arc was in the focus of the M.I. lens.

Experiments were also made with the arc raised 2 or more inches above, and depressed 2 or more inches below the focal plane.

The object of these experiments was to determine the intensity in various parts of the diverging electric beam when the light was placed nearer to the lens than its principal focus. This may give some idea of the loss of light from the parts of any burner which are out of focus, and which, therefore, give ex-focal light.

Take, first, the relative values of the illumination given by the M.I. lens with arc in focus, and by the cylindrical lens with vertical prisms with arc in focus.

A determination by myself on February 28th, gave the ratio of lights from M.I. lens to V.P. as 12 to 1.

A determination by Mr. Longford the same evening, also gave the ratio of M.I. lens to V.P. as that of 12 to 1.

A determination by Mr. Hall on March 5th, gave the ratio of M.I. lens to V.P. as 12·8 to 1.

A determination by Mr. Dixon on March 3rd, also gives the ratio about 12·1 to 1.

Hence we may assume that for an observer at a distance the magnifying power of the M.I. lens is 12 times the magnifying power of the cylindrical lens with vertical prisms.

Theoretical Discussion.

Method of using the Hopkinson photometer with the Douglass standard lamp :—

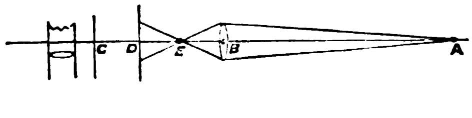

Fig. 5.

Let C be the position of the slit in front of the Douglass standard.

Digitized by Google

D the position of the Bunsen or star disc.
B the lens of the Hopkinson photometer.
E the conjugate focus to A, which is the source of light. Let A B = u, E B = v, and f the focal length of the lens.

Then the illumination of D is the same as if E were the source of light. The intensity at—

$$E=\frac{1}{c}\times L\times\frac{B\,E^2}{A\,B^2}=\frac{1}{c}\cdot L\times\frac{v^2}{u^2}=\frac{L}{c}\left(\frac{f}{u-f}\right)^2$$

where $\frac{1}{c}$ is the coefficient of absorption of the lens.

Hence if λ be the intensity of the standard at c—

$$\text{then }\frac{c\,\lambda}{C\,D^2}=\frac{L\times f^2}{E\,D^2\times(u-f)^2}$$

$$\text{or } L=c\,\lambda\left(\frac{E\,D}{C\,D}\right)^2\times\left(\frac{u-f}{f}\right)^2$$

The values of E D and C D were read off on a scale, if d be the reading for the slit C, r the reading for the disc, and a the reading for the image E,

$$\text{then } L=\lambda\left(\frac{r-a}{d-r}\right)^2\times\frac{c}{f^2}\times(u-f)^2.$$

The value of $c=1{\cdot}083$ and $f=1{\cdot}933$in. = ·161ft. for the Hopkinson lens.

Method of Measuring Lights at a Distance.

1. When a lens, such as a lighthouse lens, is placed in the path of the beam so as to have the point A, the source of light, accurately at its principal focus, then the rays between the two lenses are parallel to the axis, and if f_1 be the focal length of the lighthouse lens, the intensity at A is—

$$L=\lambda\left(\frac{r-a}{d-r}\right)^2\times\frac{c}{f^2}\times c_1 f_1^2.$$

If, in addition, the absorption of light by the atmosphere is taken into account, and if a be its coefficient of transparency,

$$\text{then } L=\lambda\left(\frac{r-a}{d-r}\right)^2\times\frac{c}{f^2}\times c_1 f_1^2\times\frac{1}{a^l}$$

when l is the distance between the two lenses.

(To be continued.)

ELECTRIC LIGHT LICENSE.

(Concluded from page 97.)

11. The Undertakers may from time to time alter the position of any pipes or wires, being under any street or place authorised to be broken up by them, which may interfere with the exercise of their powers under the principal Act or this License; and any body or person may in like manner alter the position of any electric lines or works of the Undertakers, being under any such street or place as aforesaid, which may interfere with the lawful exercise of any powers vested in such body or person in relation to such street or place, subject to the following provisions unless otherwise agreed between the parties interested:—

(*a.*) One month before commencing any such alteration the Undertakers, or such body or person (as the case may be), in this section referred to as "the operators," shall serve a notice upon the body or person for the time being entitled to such pipes, wires, electric lines, or works (as the case may be), in this section referred to as "the owners," describing the proposed alteration, and stating the amount of compensation proposed to be made in respect thereof, and the manner in which such compensation is proposed to be paid or secured, together with a plan showing the manner in which it is intended that such alterations shall be made, and shall, upon being required to do so by any such owners, from time to time give them any such further information in relation thereto as they may desire.

(*b.*) Within three weeks after the service of any such notice and plan upon any owners, such owners may, if they think fit, serve a requisition upon the operators requiring that any question in relation to such works and any other question arising upon such notice or plan as aforesaid shall be settled by arbitration; and thereupon such question shall be settled by arbitration accordingly.

(*c.*) In settling any question under this section an arbitrator shall have regard to any duties or obligations which the owners may be under in respect of such pipes, wires, electric lines, or works, and may, if he thinks fit, require the operators to execute any temporary or other works so as to avoid interference with any purpose for which such pipe, wire, electric line, or work is used so far as may be possible.

(*d.*) Where no such requisition as in this section mentioned is served upon the operators, the owners shall be held to have agreed to the notice or plan served on them as aforesaid, and in such case, or where, after any such requisition has been served upon them, any question required to be settled by arbitration has been so settled, the operators upon paying or securing any compensation which they may be required to pay or secure in the manner proposed by them or settled by arbitration as aforesaid, may cause the alterations specified in such notice and plan as aforesaid to be made, but subject in all respects to the provisions of this License and the principal Act, and only in accordance with the notice and plan so served by them as aforesaid, or such modifications thereof respectively as may have been settled by arbitration as hereinbefore mentioned, or as may be agreed upon between the parties.

(*e.*) At any time before any operators are entitled to commence any such alterations as aforesaid the owners may serve a statement upon them, stating that they desire to execute such alterations themselves, and where any such statement has been served upon the operators they shall not be entitled to proceed themselves to execute such alterations except where they have notified to such owners that they require them to execute such alterations, and such owners have refused or neglected to comply with such notification as hereinafter provided.

(*f.*) Where any such statement as last aforesaid has been served upon the operators, they shall, not more than forty-eight hours and not less than twenty-four hours before the execution of such alterations is required to be commenced, serve a notification upon the owners stating the time when such alterations are required to be commenced, and the manner in which such alterations are required to be made.

(*g.*) Upon receipt of any such notification as last aforesaid, the owners may proceed to execute such alterations as required by the operators, subject to the like restrictions and conditions as the operators would themselves be subject to in executing such alterations so far as the same may be applicable.

(*h.*) If the owners decline, or for twenty-four hours after the time when any such alterations are required to be commenced, neglect to comply with such notification, the operators may themselves proceed to execute such alterations in like manner as they might have done if no such statement as aforesaid had been served upon them.

(*i.*) All expenses properly incurred by any owners in complying with any notification of any operators under the last preceding sub-sections shall be repaid to them by such operators.

(*j.*) Any owners may, if they think fit, by any statement served by them upon any operators under this section, require the operators to give them such security for the repayment to them of any expenses to be incurred by them in executing any alterations as above mentioned as may be agreed upon between such owners and operators, or in default of agreement as may be determined by arbitration, and where any operators have been so required to give security they shall not be entitled to serve a notification upon the owners requiring them to execute any alterations until such security has been duly given.

(*k.*) If the operators make default in complying with any of the requirements or restrictions of this section they shall (in addition to any other compensation which they may be liable to make under the provisions of this License or the principal Act) make full compensation to the owners affected thereby for any loss, damage, or penalty which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding ten pounds for every such default, and in the case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such default continues; provided that the operators shall not be subject to any such additional penalties as aforesaid if the Court having cognizance of the case are of opinion that the case was one of emergency, and that the operators complied with the requirements of this section so far as was reasonable under the circumstances.

12. Whenever the Undertakers require to dig or sink any trench for laying down any new electric lines (other than service lines) or other works near to which any pipe belonging to any gas or water company, or any branch or service pipe for the supply of gas or water has been lawfully placed, or where any gas or water company require to dig or sink any trench for laying down any new mains or pipes other than service pipes or other apparatus near to which any electric lines or works of the Undertakers have been lawfully placed, the Undertakers or such gas or water company (as the case may be), in this section referred to as "operators," shall, unless otherwise agreed between the parties interested, give to such gas or water company, or to the Undertakers (as the case may be), in this section referred to as "the owners," not more than forty-eight hours and not less than twenty-four hours' notice before commencing to dig or sink such trench as aforesaid, and such owners shall be entitled by their officers to superintend the digging or sinking of such trench, and the operators shall conform with such reasonable requirements as may from time to time be made by the owners or any such officer for the protection of every such pipe, electric line, or work, and for securing the same from injury, and they shall also, if required to do so by the owners thereof, repair any damage that may be done thereto.

If the operators make default in complying with any of the requirements or restrictions of this section, they shall make full compensation to the owners of any pipe, electric line, or work affected thereby for any loss or damage which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding ten pounds for every such default, and in the case of a continuing offence to a further penalty not exceeding five pounds for every day after the first day during which such default continues: Provided that the operators shall not be subject to any such penalty if the Court having cognizance of the case are of opinion that the case was one of emergency and that the operators complied with the requirements and restrictions of this section so far as was reasonable under the circumstances, or that the default in question was due to the fact that the operators were ignorant of the position of the pipe, electric line, or work affected thereby, and that such ignorance was not owing to any negligence on the part of the operators.

For the purposes of this section the expression "gas or water company" shall include any body or person supplying gas or water.

13. Seven days before commencing to lay down any electric line, or to supply electricity through any electric line in any manner whereby the work of telegraphic or telephonic communication through any wires or lines lawfully laid down or placed in any position may be injuriously effected, the Undertakers shall, unless otherwise agreed between the par-

Digitized by Google

ties interested, give to the body or person for the time being entitled to such wires or lines notice in writing specifying the course, nature, and gauge of such electric lines, and the amount and nature of the current intended to be sent along the same, and the extent to and manner in which, if at all, earth returns are proposed to be used; and the Undertakers shall conform with such reasonable requirements as may from time to time be made by such body or person as aforesaid for the purpose of preventing communication through such wires or lines from being injuriously affected as aforesaid.

If any difference arises between any such body or person and the Undertakers with respect to the reasonableness of any requirements so made, such difference shall be determined by arbitration.

Provided that nothing in this section shall apply to repairs or renewals of existing electric lines so long as the character and position thereof is not altered, nor to the laying of connections with mains where the direction of the electric line so laid down crosses the direction of the said telegraphic or telephonic wires or lines at right angles at the point of shortest distance, and such directions continue the same for a distance of 6ft. on each side of such point.

If the Undertakers make default in complying with any of the requirements or restrictions of this section they shall make full compensation to the body or person entitled to any such wire or line as aforesaid for any loss or damage which they may incur by reason thereof, and in addition thereto they shall be liable to a penalty not exceeding five pounds for every such default, and in the case of a continuing offence to a further penalty not exceeding forty shillings for every day after the first day during which such default continues: Provided that the Undertakers shall not be subject to any such penalties as aforesaid if the Court having cognizance of the case are of opinion that the case was one of emergency, and that the Undertakers complied with the requirements and restrictions of this section so far as was reasonable under the circumstances, or that the default in question was due to the fact that the Undertakers were ignorant of the position of the wires or lines affected thereby, and that such ignorance was not owing to any negligence on the part of the Undertakers.

Maps.

14. The Undertakers shall forthwith, after commencing to supply electricity under this License cause a map to be made of the area of supply on such a scale as may from time to time be prescribed by the Board of Trade, and shall cause to be marked thereon the line of all their then existing mains, service lines, and other underground works and distributing boxes, and shall once in every year cause such map to be corrected and such additions to be made thereto as will show the line of all their then existing mains, service lines, and other underground works and distributing boxes.

15. Every map so made or corrected for the Undertakers, or a copy thereof, with the date expressed thereon of the last time when it was so corrected, shall be kept by the Undertakers at their office, and a copy of every such map shall within one month after such map is made or corrected be served by the Undertakers upon the Board of Trade and upon the Postmaster-General, and where the Local Board are not themselves the Undertakers upon the Local Board, and any copy so served upon the Local Board shall be kept by them at their office.

Every map or copy kept by the Local Board at their office under the provisions of this section, shall at all reasonable times be open to the inspection of all applicants, and such applicants may take copies of the same or any part thereof.

The Local Board may demand and take from every such applicant as aforesaid such fee not exceeding one shilling for each inspection of such map or copy, and such further fee not exceeding one shilling for each copy of the same, or any part thereof, taken by such applicant, as they may from time to time prescribe.

16. If the Undertakers fail to comply with any of the requirements of the last preceding sections of this License with respect to maps, they shall for every such offence be liable to a penalty not exceeding £10 and to a further penalty not exceeding £2 for every day after the first day during which such offence continues.

Testing.

17. The Undertakers shall, if and when required to do so by the Board of Trade from time to time, at their own cost, provide such reasonable number of testing places and provide and keep in efficient working order such suitable instruments at such testing places and upon any premises from which they supply electricity through any distributing mains for the purposes of general supply, and take and record such observations and give such facilities for the testing of the supply of electricity given by them, and the mains electric lines and works used by them for the purposes of such supply, by such persons as may be directed by the Board of Trade, and in default of so doing, they shall be liable to a penalty not exceeding five pounds for every such default, and in the case of a continuing offence to a further penalty not exceeding one pound for every day after the first day during which such offence continues.

18. If at any time it appears to the Board of Trade that any mains, electric lines, or works, of the Undertakers are defective and not in accordance with the regulations and conditions subject to which the Undertakers are for the time being authorised to supply electricity under this License, the Board of Trade may by order in writing require the Undertakers to remedy such defect so as to comply with such regulations and conditions within such period as may be therein limited in that behalf, and if the Undertakers make default in remedying such defect within the time so limited, they shall be liable to a penalty not exceeding twenty pounds for every day during which such default continues. Provided that if such defect is in the opinion of the Board of Trade dangerous to public safety, they may also, by any such order as aforesaid, forbid the use of such main, electric line, or work as from such date as may be specified in that behalf until the defect is remedied, and if the Undertakers make use of any such main, electric line, or work, while the use thereof is so forbidden, they shall be liable to a penalty not exceeding one hundred pounds for every day during which such user continues.

Supply.

19. The Undertakers shall, upon being required so to do at any time within six years after the commencement of this License, by the owner or occupier of any premises situated within twenty-five yards from any distributing main of the Undertakers, in which they are for the time being required to maintain a current of electricity for the purposes of general supply under this License or any regulations or conditions subject to which they are authorised to supply electricity under this License, give and continue to give a supply of electricity for such premises, in accordance with the provisions of this License, and of all such regulations and conditions as aforesaid, and they shall furnish and lay any electric lines that may be necessary for the purpose of supplying the maximum current with which any such owner or occupier may be entitled to be supplied under this License, subject to the conditions following; (that is to say),

The cost of so much of any electric line for the supply of electricity to any owner or occupier as may be laid upon the property of such owner or in the possession of such occupier, and of so much of any such electric line as may be laid for a greater distance than thirty feet from any distributing main of the Undertakers, although not on such property, shall be defrayed by such owner or occupier.

Every owner or occupier of premises requiring a supply of electricity shall—

Serve a notice upon the Undertakers at their office, specifying the premises in respect of which such supply is required and the maximum current required to be supplied, and the day (not being an earlier day than a reasonable time after the date of the service of such notice) upon which such supply is required to commence:

Enter into a written contract with the Undertakers (if required by them so to do) to continue to receive and pay for a supply of electricity for a period of at least two years, or for a residue of the term of this License where such residue is less than two years, of such an amount that the rent payable for the same, at the rate of charge for the time being charged by the Undertakers for a supply of electricity to ordinary consumers within the area of supply, shall not be less than twenty pounds per centum per annum on the outlay incurred by the Undertakers in providing any electric line to be provided by them for the purpose of such supply, and give to the Undertakers (if required by them so to do) reasonable security for the payment to them of all moneys which may from time to time become due to them by such owner or occupier in respect of any electric lines to be furnished by the Undertakers, and in respect of electricity to be supplied by them.

Provided always, that the Undertakers may, after they have given a supply of electricity for any premises, by notice in writing require the owner or occupier of such premises, within seven days after the date of the service of such notice, to give to them such reasonable security as aforesaid, in case such owner or occupier has not already given such security, or in case any security given has become invalid or is insufficient; and where any such owner or occupier fails to comply with the terms of such notice, the Undertakers may, if they think fit, discontinue to supply electricity for such premises so long as such failure continues.

Provided also that if the owner or occupier of any such premises as aforesaid uses any form of lamp or burner, or uses the electricity supplied to him by the Undertakers for any purpose or deals with it in any manner so as to unduly or improperly interfere with the supply of electricity to any other body or person by the Undertakers, the Undertakers may, if they think fit, discontinue to supply electricity to such premises so long as such user continues.

If any difference arises between any such owner or occupier and the Undertakers as to the reasonableness of the amount of any security required to be given or as to the sufficiency of any security offered under this section such difference shall be determined by arbitration.

20. The maximum current with which any such consumer, as in the last section mentioned, shall be entitled to be supplied shall be of such amount as he may from time to time require to be supplied with, not exceeding what may be reasonably anticipated as the maximum consumption on his premises: Provided that where any consumer has required the Undertakers to supply him with a maximum current of any specified amount, he shall not be entitled to alter that maximum except upon one month's notice to the Undertakers, and any expenses incurred by the Undertakers in respect of the service lines by which electricity is supplied to the premises of such consumer, or any electric lines, fittings, or apparatus of the Undertakers upon such premises, consequent upon such alteration, shall be paid by him to the Undertakers.

If any difference arises between any such owner or occupier and the Undertakers as to what may be reasonably anticipated as the consumption on his premises such difference shall be determined by arbitration.

21. Whenever the Undertakers make default in giving a supply of electricity to any owner or occupier of premises in accordance with the terms of this License and of any regulations and conditions subject to which they are authorised to supply electricity under this License, they shall be liable to a penalty not exceeding forty shillings in respect of every such default for each day upon which any such default occurs.

Provided that the penalties to be inflicted on the Undertakers under this section shall in no case exceed in the aggregate the sum of one hundred pounds in respect of any defaults in supplying private consumars for any one day, and provided also that in no case shall any penalty be inflicted in respect of any default if the Court having cognizance of the case should be of opinion that such default was caused by inevitable acci-

Digitized by Google

dent or by force majeure, or was of so slight or unimportant a character as not materially to affect the value of the supply.

Price.

22. The Undertakers may charge for electrictity supplied by them from any distributing main to any ordinary consumer (otherwise than by agreement)—

(1.) By the quantity of energy contained in such supply; or,

(2.) By the actual quantity of electricity so supplied; or,

unless the Board of Trade from time to time otherwise direct,

(3.) By the number of hours during which the supply of electricity is actually used by such consumer, and the maximum current with which he is for the time being entitled to be supplied:

Provided that before commencing to supply electricity through any distributing main for the purposes of general supply, the Undertakers shall give notice to all consumers into whose premises service lines have been laid from such main by what method they propose to charge for electricity supplied through such main; and, where the Undertakers have given any such notice, they shall not be entitled to change such method of charging except after one month's notice of such change has been given by them to every consumer of electricity who is supplied by them from such main.

23. The prices to be charged by the Undertakers for electricity supplied by them shall not exceed those stated in that behalf in Schedule A in the first, second, and third sections thereof respectively.

24. Subject to the provisions of this License and of the principal Act, and to the right of the consumer to require that he shall be charged according to some one or other of the methods above mentioned in cases where he is entitled to require a supply, the Undertakers may make any agreement with a consumer as to the price to be charged for electricity, and the mode in which such charges are to be ascertained, and may charge accordingly.

Application of Revenue.

25. All moneys from time to time received by the Local Board in respect of the undertaking, except borrowed money, shall be applied by them as follows:—

(1.) In payment of the working and establishment expenses and cost of maintenance of the undertaking, including all costs, expenses, penalties, and damages incurred or payable by the Local Board, consequent upon any proceedings by or against the Local Board, their officers or servants, in relation to the undertaking.

(2.) In payment of the interest on any mortgages, stock, or other securities granted and issued by the Undertakers in respect of money borrowed for electricity purposes.

(3.) In providing any instalments or sinking fund required to be provided in respect of moneys borrowed for electricity purposes.

(4.) In payment of all other their expenses of executing this License, not being expenses properly chargeable to capital.

And shall carry the net surplus remaining in any year to the credit of the local rate as defined by the Electric Lighting Act, 1882.

Any deficiency of income in any year shall be charged upon and payable out of the local rate aforesaid.

Notices, &c.

26. Notices, orders, and other documents under this License may be in writing or in print, or partly in writing and partly in print; and where any notice, order, or document requires authentication by the Local Board, the signature thereof by the clerk or surveyor to the Local Board shall be sufficient authentication.

27. Any notice, order, or document required or authorised to be served upon any body or person under this License, or the principal Act, may be served by the same being addressed to such body or person and being left at or transmitted through the post to the following addresses respectively:—

(*a.*) In the case of the Board of Trade, the office of the Board of Trade;

(*b.*) In the case of the Postmaster-General, the General Post Office;

(*c*) In the case of the Local Board, the office of the Local Board or their clerk;

(*d.*) In the case of the justices of the peace for any county, the office of the clerk of the peace for the said county;

(*e.*) In the case of any company having a registered office, the registered office of such company;

(*f.*) In the case of a company having an office or offices, but no registered office, any such office;

(*g.*) In the case of any other person, the usual or last known place of abode of such person.

Where any notice is served by post it shall be deemed to have been served at the time when the letter containing the notice would be delivered in the ordinary course of post, and in proving such service it shall be sufficient to prove that the letter containing the notice was properly addressed and put into the post.

A notice, order, or document by this License required or authorised to be served on the owner or occupier of any premises shall be deemed to be properly addressed if addressed to the "owner" or "occupier" of the premises (naming the premises), without further name or description.

A notice, order, or document by this License required or authorised to be served on the owner or occupier of any premises may be served by delivering the same, or a true copy thereof, to some person on the premises, or if there is no person on the premises to whom the same can with reasonable diligence be delivered, by fixing the notice on some conspicuous part of the premises.

Expiration or Revocation of License.

28. In addition to any other powers which the Board of Trade may have in that behalf, they may revoke this License at any time with the consent and concurrence of the Undertakers, and also where the Local Board are not themselves the Undertakers of the Local Board, upon such terms as the Board of Trade may think fit.

29. If the Board of Trade at any time revoke this License as to the whole or any part of the area affected thereby, under any of the provisions of this License, the Board of Trade shall serve a notice of such revocation upon the Undertakers, and where the Local Board are not themselves the Undertakers upon the Local Board, and shall in such notice fix a date at which such revocation shall take effect, and from and after such date all the powers of the Undertakers and the Local Board for the supply of electricity under this License within such area, or part thereof as aforesaid, shall absolutely cease and determine.

30. Except so far as may be otherwise specially provided by any license, order, or special Act to be hereafter granted or passed, upon the expiraiion of the term of this License, or upon the revocation of this License as to the whole or any part of the area affected thereby, any body or person who may be liable to repair any street or part of a street within such area or part thereof in which any works of the Undertakers may have been placed, may forthwith remove such works, with all reasonable care, and the Undertakers shall pay to such body or person such reasonable costs of such removal as may be specified in a notice to be served on the Undertakers by such body or person, or (if so required by the Undertakers, within one week after the service of such notice upon them) as may be settled by arbitration.

If the Undertakers fail to pay such reasonable costs as aforesaid within one month after the service upon them of such notice or the delivery of the award of the arbitrator, as the case may be, such body or person as aforesaid may, without any previous notice to the Undertakers (but without prejudice to any other remedy which they may have for the recovery of the amount), sell and dispose of any such works as aforesaid either by public auction or private sale, and for such sum or sums, and to such body or person as they may think fit; and may, out of the proceeds of such sale, pay and reimburse themselves the amount of the costs so specified or settled as aforesaid, and of the costs of sale, and the balance (if any) of the proceeds of the sale shall be paid over by such body or person to the Undertakers.

Transfer of Undertaking.

31. At any time after the commencement of this License the Local Board may, with the consent of the Board of Trade, transfer all or any part of the powers, duties, and liabilities conferred or imposed upon them by this License, as to the whole or any part of the district, together with any lands or works vested in or belonging to them for the purposes of this License, to any other body or person.

General.

32. The Board of Trade may from time to time upon the application of the Undertakers, and upon such conditions (if any) as the Board of Trade think just, suspend or modify any obligation of the Undertakers with respect to the supply of electricity under this License for any period as to the whole or any part of the area of supply.

33. Where the approval or consent of the Board of Trade is given in any case, or where the Board of Trade makes any order or gives any notice under the provisions of this Licence, such approval or consent shall be signified or such order shall be made or notice given in writing under the hand of one of the secretaries or assistant secretaries of the Board of Trade.

34. All costs and expenses of or incident to any application for the approval or consent of the Board of Trade, including the costs of the tests (if any) which may be required to be made by the Board of Trade for the purpose of determining whether such approval or consent should be given, shall be borne and paid by the applicant or applicants for such approval or consent; provided always that where any approval is given by the Board of Trade to any plan, pattern, or specification, they may require such copies of the same as they may think fit to be prepared and deposited at their office at the expense of the said applicant or applicants, and may from time to time, if they think fit, revoke any approval so given, or permit such approval to be continued subject to such modifications as they may think necessary.

35. Where the Board of Trade, upon the application of the Undertakers, give any approval or suspend or modify any obligation of the Undertakers under this License, or revoke this License as to the whole or any part of the area affected thereby, or where any transfer of any powers, duties, or liabilities under this License has been effected by the Local Board with the consent of the Board of Trade to any other body or person, notice that such approval has been given, or such obligation suspended or modified, or such revocation made, or such transfer effected, shall be published by public advertisement once at least in each of two successive weeks in some one and the same local newspaper by the Undertakers.

36. The Undertakers shall be answerable for all accidents, damages, and injuries happening through the act or default of the Undertakers, or of any person in their employment by reason or in consequence of any of the Undertaker's works, and shall save harmless all other bodies and persons collectively and individually, and their officers and servants, from all damages and costs in respect of such accidents, damages, and injuries.

37. Nothing in this License shall authorise the Undertakers to take, use, or in any manner interfere with any portion of the shore or bed of the sea, or of any river, channel, creek, bay, or estuary, or any right in respect thereof, belonging to the Queen's most Excellent Majesty, in right of her crown, and under the management of the Board of Trade, without the previous consent of the Board of Trade on behalf of Her Majesty (which consent the Board of Trade may give); neither shall anything in this License contained extend to take away, prejudice, diminish, or alter any of the estates, rights, privileges, powers, or authorities vested in, or enjoyed or exercisable by, the Queen's Majesty, her heirs or successors,

Digitized by Google

38. The Undertakers shall not construct on the shore of the sea, or of any creek, bay, or arm of the sea, or navigable river communicating therewith, where and so far up the same as the tide flows and re-flows, any work without the previous consent of the Board of Trade, and then only according to such plan and under such restrictions and regulations as the Board of Trade may approve of; and where any such work may have been constructed, the Undertakers shall not at any time alter or extend the same without obtaining previously to making any such alteration or extension the like consents or approvals. If any such work be commenced or completed contrary to the provisions of this License, the Board of Trade may abate and remove the same, and restore the site thereof to its former condition at the cost and charge of the Undertakers.

39. Nothing in this License shall affect any right or remedy of the Postmaster-General under the Electric Lighting Act, 1882, or the Telegraph Acts, 1863 to 1878, and all provisions contained in this License in favour of the Postmaster-General shall be construed to be in addition to and not in modification of the provisions of those Acts.

40. Nothing in this License shall exonerate the Undertakers from any indictment, action, or other proceeding for nuisance in the event of any nuisance being caused by them.

41. Nothing in this License shall exempt the Undertakers or their undertaking from the provisions of any general Act relating to the supply of or price to be charged for electricity which may be hereafter passed.

SCHEDULE A.

The term "unit" as used in this schedule shall be deemed to mean the quantity of energy contained in a current of 1,000 amperes flowing under an electromotive force of one volt during one hour.

SECTION 1.

Where the Undertakers charge any consumer by the quantity of energy contained in the supply given to him, they shall be entitled to charge him at the following rates per quarter:—For any quantity up to 100 units, three pounds ten shillings; for each unit over 100 units, sevenpence per unit.

SECTION 2.

Where the Undertakers charge any consumer by the actual quantity of electricity supplied to him, they shall be entitled to charge him according to the rates set forth in section 1 of this schedule, the quantity of energy contained in the supply given to him being taken to be the product of the actual quantity of electricity supplied to him and the standard pressure at the point of junction of the mains and the service lines by which he is supplied.

SECTION 3.

Where the Undertakers charge any consumer by the number of hours during which he actually uses his supply, they shall be entitled to charge him at the rate specified in section 2 of this schedule, the quantity of electricity supplied to him being calculated on the supposition that the consumer uses the maximum current specified by him under the provisions of this License during all the hours that he has used the supply.

SCHEDULE B.

Railway and tramways which may be broken up by the Undertakers in pursuance of the special powers granted by this License:—

The Furness Railway.
Tramways belonging to—
The Barrow Hematite Steel Company (Limited);
The Ulverston Mining Company (Limited);
The Askam and Mouzell Iron Company (Limited);
Messrs. Harrison, Ainslie, and Co.;
The Elliscales Mining Company (Limited);
Messrs. Kennedy Brothers;
The Trustees of Myles Kennedy;
The Sandscale Mining Company.

COMPANIES' MEETINGS.

The Swan Electric Light Company.

An ordinary general meeting of the shareholders was held at the City Terminus Hotel, Cannon-street, on Wednesday last, Mr. J. S. Forbes presiding.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said he was sorry to have called the shareholders together to attend a *pro formâ* meeting; but under the Articles of Association a meeting must be held once a year, and therefore they could not help themselves. He was not in a position, however, to lay before them any report, or to tell them very much except this, that the Directors would feel themselves in February prepared to present a report and statement of accounts, and to deal with the condition of the Company when they knew it. The fact was, as the notice indicated, very important negotiations were now pending in Germany, where, he was sorry to say, they were engaged in litigation; and he thought he could only indicate generally this—that it was very much in the interest of those negotiations, and of this Company, that they should adjourn the meeting until February. He had, in company with Major Flood Page, spent recently some time in Germany, trying to do there what they had done, he thought, with satisfactory results in England—namely, seeing if they could not reconcile divergent interests, and, instead of the Edison Company and the Swan Company abroad cutting each other's throats, to ascertain whether they could not, upon some terms or other, have a treaty of peace, or an actual fusion of interests. His own impression was, without predicting too much, or without being too sanguine, that now the common sense, so to speak, of the parties was fastened upon the results of litigation, possibly some advantageous arrangement to both sides might come out of the pending negotiations. Meanwhile they must not be alarmed if they heard that certain formal law proceedings were going on in Germany. There was one satisfaction in German law—it was equally slow with law in England, but very much less costly. He would feel rather uncomfortable if they had the same number of suits pending in any law court in England as they had in Germany. But he was not at all concerned, because he did not think they would really come to anything. On the contrary, he believed the Directors would succeed in putting an end to litigation of every kind by an agreement which would be beneficial, not only to the Swan but to the Edison Company as well. He hoped the shareholders would repose sufficient confidence in the Directors to leave them to carry out those negotiations. He did not think it would be advantageous to the Company to enter into much detail at present, and he would, therefore, move the adjournment of the meeting until the 23rd of February.

Mr. CUTHBERT QUILTER, M.P., seconded the motion, which was carried unanimously.

Mr. VERITY thought there was no occasion to send out any proxies, believing, as he did, that the Board possessed the confidence of all the shareholders.

The CHAIRMAN said it was very kind of the hon. proprietor to say so, but the experience of the Directors was not of a character to justify their going forward unprepared with any policy. Besides, there was some moral support to the Board in feeling that they had the tangible support of the large body of proprietors who did not think it worth while to come to their meetings. They liked to feel the support involved in large proprietors, who never took the trouble to come near them, sending in their proxies. The expense in connection with the subject was very small, and under the present circumstances he thought the practice was a safeguard which it might be a little dangerous to relax.

The proceedings then terminated.

Business Notice.—Messrs. Laing, Wharton and Down, electrical engineers and contractors, 8 and 9, Holborn-viaduct, E.C., have taken into partnership Mr. Arthur F. Davies, late of Lambton and Co., bankers, Newcastle-on-Tyne, who will more especially take charge of the commercial and financial departments, in the place of the late Mr. Laing, who died about a year ago.

NOTES.

BRITISH GUIANA.—The cable between Trinidad and Demerara is interrupted.

A NEW CABLE.—The cable connecting Nantucket with Martha's Vineyard, U.S.A., has been successfully landed.

OBITUARY.—The death is announced of Mr. Alfred Tribe, the well known chemist, on the 26th ultimo, at the age of forty-six years.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 18th inst. amounted to £3,395.

EASTERN TELEGRAPH COMPANY.—This company notify the opening for traffic of two new stations in China, viz., Kaiping and Shaoking, the rate being 10s. per word.

UNDERGROUND WIRES.—The Dorsett Underground Service Company has been incorporated, the object being to lay electric conduits in Milwaukee. The capital stock is £100,000.

THE TELEPHONE LITIGATION IN AMERICA.—It is officially stated that the legal expenses of sustaining the Bell patent have already amounted to considerably more than £100,000.

NOT READY.—The Society "Stædtischen Elektricitætswerke" of Berlin will not be able to commence operations before the beginning of the new year, as their machines are as yet unfinished.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th December are £2,438, as compared with £2,260 in the corresponding period of 1884.

THE PHOTOPHORE.—At a recent meeting of the Royal Microscopical Society, Mr. J. Mayall, jun., exhibited the Helot-Trouvé electric photophore, which had been recommended as an excellent illuminant for microscopical purposes.

THE LATE METEORIC SHOWER.—The correspondent of a contemporary, writing from Switzerland, reports that during the recent meteoric shower he set up a coulomb torsion electrometer and found the air highly charged with electricity.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due on the 31st inst. on the debentures of this Company, will be paid by Messrs. Barclay, Bevan and Co. The coupons must be sent in three clear days for examination.

THE TELEPHONE COMPANY OF AUSTRIA.—This company notify that coupon No. 2 on their Five per cent. Debenture Bonds, due January 1st, will be paid (less income-tax) on and after that date by Messrs. Martin and Co., Lombard-street, E.C.

THE EAST ANGLIAN EARTHQUAKE.—A report of this earthquake, which occurred, it will be remembered, on the 22nd of April last year, is about to be published by Messrs. Macmillan and Co. It has been drawn up by Prof. Meldola and Mr. W. White.

BURMAH.—A telegram from Mandalay, dated December 17th, reports that two squadrons of Madras Cavalry have arrived there, and that one troop left on that day in order to make arrangements with the Woons for keeping the telegraph wire intact.

MATHEMATICAL SOCIETY.—At a meeting of this society held on the 10th inst. Mr. A. B. Basset read a communication entitled, a "note on the induction of electric currents in an infinite plane current sheet which is rotating in a field of magnetic force."

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 18th December were £2,619, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

AT A BAZAAR.—At a fancy bazaar held at Brentford in aid of the Building Fund of the British Schools, one of the rooms was illuminated by incandescent lamps, the power being obtained from E.P.S. accumulators. The work was carried out by Messrs. Nalder Bros.

THE DIELECTRIC STRENGTH OF GASES.—At a recent meeting of the Philosophical Society of Cambridge, Dr. C. Olearski described a series of experiments from which it followed that the dielectric strength of a mechanical mixture of two gases is intermediate between the strengths of its constituents.

THE ELECTRICAL CONDITION OF THE HUMAN BODY.—An article upon the human body considered as an inductive element in electrical testing appears in the current issue of the *Electrical Engineer*. The point raised is a novel one, and we would draw the attention of our readers to the article in question.

RIVER ILLUMINATION IN CHICAGO, U.S.A.—Advices from Chicago report that it is proposed to light up the river banks by electric lights, and then urge an ordinance restricting all outgoing vessels from passing through the river during daylight. Vessels arriving will of course be permitted to make harbour.

BICHROMATE CELLS.—We advise our young readers who may amuse themselves with experimental lighting by bichromate of potash cells to prepare the solution by crushing the bichromate and dissolving in cold water. To get the maximum of effect the sulphuric acid should be added *drop by drop*. The slower the better.

GOOD!—During a sermon which he delivered recently at the Presbyterian Church, Islington, Dr. Thain Davidson said, "I am told that the submarine telegraph cable in Bass's Straits, weighing ten tons a mile, was actually floated to the surface by sea-weed which attached itself to it." We should like to see a specimen of that sea-weed.

THE ELECTRIC LIGHT AND FISHING BOATS.—A fishing steamer at Portland (Me.) has been fitted with electric light for night fishing. If the experiment proves successful, the steam whalers stationed at Province-town will probably be fitted with the lights for night cruising. The light is placed on the bows, near the pilot house, and is run by the steam hoister.

THE S.S. "MIRROR."—On Monday the s.s. "Mirror," the new cable ship built by Messrs. Napier and Sons, of Govan, for the Eastern Telegraph Company, was successfully launched from their yard on the Clyde, the ceremony of christening the vessel being performed by Lady Thomson. Amongst those present were Sir James Anderson, and Sir Wm. Thomson.

THE S.S. "GREAT NORTHERN."—The s.s. "Great Northern," the cable steamer belonging to the Eastern and South African Telegraph Company, having undergone a thorough overhauling, has been recommissioned for the East Coast of Africa, to relieve the s.s. "Chiltern." The command will be taken by Captain Smith, Mr. W. H. Cottrell resuming charge of the electrical department.

ELECTRIC LIGHTING OF OLD LEADENHALL MARKET.—The extensive premises of Messrs. G. F. Brooke and Company, of Old Leadenhall Market, have been lighted by six arc lamps and a number of incandescents, the dynamo being driven by the 12 horse-power Crossley gas engine used by the firm for

Digitized by Google

their refrigerating process. The work has been carried out by Messrs. Craven and Elworthy.

CONTRACT OPEN.—The guardians of St. Saviour's Union, Surrey, are about to consider the subject of lighting their new infirmary at East Dulwich Grove, S.E., and are prepared to receive tenders, &c., for lighting such buildings by electricity. The tenders should be forwarded to Mr. H. C. Jones, clerk, at his offices, John-street West, Blackfriars-road, S.E., by the 13th January. Plans of the building may be seen at the offices of Messrs. Jarvis and Son, 29, Trinity-square, Borough, London, S.E.

CHROMIC ACID CELLS.—The usual printed instructions for the preparation of the chromic acid solution for batteries direct that the sulphuric acid be poured into *hot* solution of potassium dichromate; unless this be carefully done, small portions of the oil of vitrol may be projected into the face of the operator. Bunsen's method is preferable; mix the dichromate, in granular form, with the sulphuric acid, then add *cold* water, with continued stirring; the union of the acid and water generates sufficient heat to speedily effect the solution of the salt.

CHEAPER THAN GAS.—Denver, Colorado, is to be illuminated by electricity at a cost of 28 dollars per lamp, against 35 dollars, the lowest offer of the gas company. There are 450 lamps. The system is the Edison, the cost of the plant 20,000 dollars. The contractors are the Colorado Electric Company. The Denver municipal electric lighting system will comprehend twenty circuits, with twenty-seven lamps to a circuit when each circuit has its full complement. The lamp will be placed on the present gaslight posts extended up some four feet, whence the light will be thrown a greater distance than if nearer the ground.

CITY AND GUILDS OF LONDON INSTITUTE.—At a meeting of the executive committee held on Monday, it was announced that, subject to confirmation, the Mercers' Company had resolved to increase their subscription to the Institute from £2,000 a year to £3,000 a year, that the Clothworkers' Company had conditionally increased their subscription from £3,000 a year to £4,000 a year, and that the Skinners' Company had increased their subscription from £525 a year to £1,500 a year. It was also announced that the Cutlers' Company would in future contribute £105 annually to the funds of the Institute.

A NEW PERIODICAL.—We have received the first issue of a new periodical entitled, "Future Careers for our Sons and Daughters, at Home and Abroad." The contents embrace the Musical Profession; the Stage; Civil and Mechanical Engineering; the Clerical Profession; Employment of Women; the Nautical, Legal, and Scholastic Professions, and a variety of other subjects. We cut the following from the section of the paper devoted to Civil and Mechanical Engineering:—"As electricity will probably assume much greater prominence in the next generation, its application to telegraphs, railway signalling and lighting will be considered."

THE PROPOSED BERMUDA CABLE.—A contemporary says that a telegraph cable to Bermuda had long been wanted, and the Government have now recognised this by asking for tenders for laying and working one from Halifax through the island to Jamaica. The question of the defence of these cables in war time is, however, one which has not yet received the attention it deserves. One of the conditions of receiving the subsidy offered is that the Government may, in case of war, occupy any of the stations, and work the cable with its own servants. They may thus take care of the ends, but will hardly prevent it being severed in the middle.

EARTHQUAKES.—Besides the shocks of earthquake which occurred recently in the M'Sila district, disturbances have been felt at Bordj-ben-Areridj and Setif, also in Algeria. A road which was constructed not long ago from Setif to Bordj had been blocked by debris from the surrounding mountains; a bridge has also been destroyed, and a railway station demolished. It is also reported from Smyrna, in Asia Minor, that a series of seismic tremblings, commencing on the 13th ultimo had, up to the 25th ultimo, been felt at Denizulu in the interior, about 200 miles to the eastward. The shocks were very slight but were accompanied with loud subterranean noises.

BATTERY SOLUTIONS.—According to an official circular recently issued, the following are the quantities of materials to be used in charging the following descriptions of batteries used in Government departments:—Bichromates: 4ozs. of bichromate of potass and 4ozs. of sulphuric acid in the outer cell, and in the porous pot 2ozs. of mercury with a small quantity of sulphuric acid, varying according to the porosity of the cell, but in no case to exceed ½oz. Large Daniells: 5ozs. of sulphate of copper. Small Daniells: 2½ozs. of sulphate of copper Large Chambers: 3ozs. of sulphate of copper. Agglomerate and No. 1 p.p. Leclanché: 4ozs. of sal ammoniac. No. 3 p.p. Leclanché: 2ozs. of sal ammoniac.

OPENING OF A NEW CENTRAL LIGHTING STATION.—We are informed that the Brighton Electric Light Company have purchased the Brighton electric light business and plant connected therewith lately the property of the Hammond Electric Light and Power Supply Company, and have established a new central electric lighting station in the town mentioned. It may not be generally known that electricity has been for the past four years supplied in Brighton from a central station on precisely the same basis as gas—*i.e.*, the consumer has entire control over the lights he uses, being able to turn the lamps on and off just as desired, and only pays for the actual quantity of electricity used, this being determined by a reliable meter.

ELECTRIC STEERING APPARATUS.—An electrical steering apparatus, the invention of Mr. Washburn, was tested recently on the U.S.S. "Tallapoosa," in New York harbour. The invention is an electro-pneumatic steering apparatus by which a ship steers her own course automatically. The tiller is worked by compressed air, governed by electricity. The automatic principle is obtained by the introduction of an electrical mechanism into the binnacle, which, being attached to the compass at the point to which it is desired to shape the vessel's course, will hold the ship to that point, the motion of the vessel opening and shutting the circuits of the mechanism, which acts upon the rudder and corrects any deviation from the marked course.

THE TELEPHONE AT BOURNEMOUTH.—At the last meeting of the Bournemouth Improvement Commissioners, the Roads Committee reported that the manager and engineer of the Western Counties and South Wales Telephone Company attended before them and explained the system they propose for a Telephone Exchange in Bournemouth, and after hearing the explanation the committee saw no objection to the system proposed. Some discussion took place as to the question of overground or underground wires and other details, the general opinion appearing to be that as the exchange would be of benefit to the town it would be unwise on the part of the commissioners to impose restrictions which would have the effect of putting an end to the scheme. Ultimately the report was adopted.

CABLES IN ITALY.—The week before last a Bill for the putting down and maintenance of twelve submarine telegraph

Digitized by Google

cables was brought before the House. Annexed to the Bill are two agreements concluded with Messrs. Pirelli and Co., of Milan. The first contract relates to the putting down and maintenance of these cables in working order for twenty years, which the above-named firm have undertaken to do against an annual payment of 222,144 lire. Naples is to be put in direct communication with Palermo, the cable touching at the Island of Ustica on its way, and the Eolian and Lipari Islands are all to be united with a network of cables and be put in communication with the mainland. The second contract refers to the cable ship, which is to be constructed at Messrs. Pirelli's expense, but kept in repair by the Italian Government, whose property it will become on the expiration of the above mentioned term of twenty years. Its minimum dimensions are to be, length 197ft., breadth 25ft., depth 16ft.

Engineer Volunteer Companies.—The following are the new regulations made by the War Office for the formation of Engineer Volunteer Companies for railway work :—The establishment of each company is the same as laid down for ordinary Engineer Volunteers, but the detail of trades should be as a general rule as follows : Station staff—Ticket collectors or foreman porters to act as station masters (sergeants), 4 ; telegraph clerks, 4 ; porters or pointsmen, 4. Terminal staff—Traffic inspector (sergeant), 1 ; store keepers, 2 ; inspector of rolling stock (sergeant), 1 ; engine cleaners, 4 ; engine fitters (including sergeants), 4 ; shunters, 2 ; greasers (one to be a tailor and one a shoemaker), 2 ; goods porters, 4 ; clerks, 2. Train staff—Engine drivers, 9 ; firemen, 9 ; brakesmen, 9 ; maintenance gaugers (including sergeants), 3 ; platelayers, 16 ; blacksmiths and strikers, 4 ; rivetter, 1 ; boiler maker, 1 ; sawyer, 1 ; joiner, 1 ; carpenters, 2 ; bricklayer, 1 ; masons, 2 ; tin smith, 1 ; surveyor (sergeant), 1 ; draughtsman, 1.

The Channel Squadron.—According to advices received on Friday from Arosa Bay, the Channel Squadron has arrived there after having experienced a terrific gale while crossing the Bay of Biscay. The two divisions of the squadron—one from Portsmouth and the other from Plymouth—met off the Eddystone on the 9th inst., and proceeded on their winter cruise, their intention being to go first to Lisbon. On the 12th, after entering the Bay of Biscay, both wind and sea began to increase, and by the time the middle of the bay was reached a tremendous sea was running, and all the vessels shipped heavy seas, notably the two flagships "Minotaur" and "Agincourt." The "Agincourt" had both her lower booms washed away. Her electric lights were also carried completely overboard and lost. Her nettings fore and aft, as well as the aft bridges, were smashed, and the navigation bridge was seriously damaged by the seas that broke over the ship. The "Sultan" suffered principally in her rigging and sails, and the "Iron Duke" and "Monarch" were a good deal knocked about, but not to the same extent as the other ships.

Navigable Balloons.—At a recent meeting of the United States Military Service Institution, General Russell Thayer, of Philadelphia, presented in detail his system of independent and dependent balloons, intended particularly for use in war time. In the independent balloon the motor is a high pressure air compressor, coupled directly to a newly devised carbonic acid gas engine and a reservoir for storing the air until sufficient pressure is obtained. The construction of the dependent balloon is similar to that of the independent ship, except as regards the motive power, which is here electricity. The track consists of two parallel wires supported on poles above the ground. The lower deck would be provided with two large wheels constructed to run on the under side of the wires, and two small wheels to run on the upper side. This arrangement anchors the balloon to the earth, and furnishes the motive current from a dynamo at the end of the line. It is expected that a speed of at least 20 miles an hour can be obtained. A model of the balloon and track was shown, and was operated successfully.

Oh my!—Ohm! Ohm!! sweet Ohm!!!
Watt heart re-*volts* from thee ?
The constant current of our souls
Flows on from unity.
Our every test
Has proved *thou* best,
Tho' damping aliens would invest
Thy name with lesser interest ;
That is, as we do know thee.
Tho' C's may lie 'twixt thou and E
Who Faraday may roam,
E can but take himself to C
By passing thro' his ohm.
Consoling thought—e-static dream,
Tho' quantities diminish,
And mortal coils must be unwound,
Our life's helixir passes round
Uunaltered at the finish.
(At least we hope so !)

The Telephone and the Bath Corporation.—At the last meeting of the Bath Town Council the Surveying Committee reported with respect to the application to establish a telephone exchange, and recommended that the permission required should be granted, subject to the details of the work being carried out to the satisfaction of the committee. Mr. Heywood hoped that in considering the application from the telephone company they would remember that what it proposed to do was a real public improvement. Mr. Rubie pointed out that Bath was not so much a commercial town as a resort for visitors, and he was, therefore, opposed to the disfiguration of the city by these telephone wires. Mr. Sturges contended that the telephone was a thing that should be welcomed and not shelved. The company had come before them very liberally and very considerately, and deserved their very best attention. Mr. Walker asked whether it was wise for the convenience of, say, ten or twenty persons to establish a network of wires over the streets. The Mayor said in these days he thought they could not neglect the telephone. The report was adopted.

Producing Cane Sugar from Starch by Electricity.—This method, due to L. Aubert and V. Giraud, of Lyons, depends upon the formation of saccharose from starch and water by a practical method which is substantially as follows :—100 kilograms of potatoes are heated to 100° C. in 5 cubic metres of water, with 5 kilograms of sulphuric acid, and a trace of nitric acid, until the starch is dissolved. An electric current of 11 amperes is then passed through the solution between electrodes of antimonial lead, the direction of the current being changed at intervals. In about two hours' time the solution is tested with tincture of iodine and alcohol, and if no coloration or precipitate is produced the current is interrupted, and carbonate of lime and hydrate of lime, the latter in considerable excess, are added to remove dextrine and unchanged glucose. Previously to filtration and saturation of the lime with carbonic acid, some basic acetate of lead is added to remove the colouring matter, which otherwise would interfere with the crystallisation. After concentration of the liquid in the usual way, the syrup is allowed to crystalise, which however takes somewhat longer than ordinary sugar-syrup.—Abst. *Proc.* Inst. C.E.

TELEPHONE RATES IN AMERICA.—The revised yearly telephone rates in different parts of the United States are given as follows:—

	Subscribers.	Cities.	
Albany.........	—	....	£12 0 0
Baltimore ...	£20 0 0	Ordinary...............	13 9 0
		Fire Department ...	6 0 0
		Water " ...	20 0 0
Boston.........	24 0 0	....	25 0 0
Brooklyn......	20 0 0	Ordinary...............	18 0 0
		Leased instrument ...	4 0 0
Cincinnati ...	20 0 0	....	2 0 0
Chicago	25 0 0	....	4 0 0
Cleveland ...	14 8 0	....	—
Detroit.........	—	One-half usual rates...	
Lawrence......	15 0 0	....	7 4 0
Lowell.........	15 0 0	One-half usual rates...	
New York ...	30 0 0	....	25 0 0
New Haven...	12 0 0	....	—
Portland	15 0 0	One-half usual rates...	
Providence ...	12 0 0	One-half usual rates...	
St. Louis	20 0 0	....	20 0 0
Worcester ...	15 0 0	Instruments at special rates; connect free.	

BRIGHTON.—Mr. Magnus Volk, electrical engineer to the Corporation of Brighton, and proprietor of the electric railway now permanently established on the eastern part of the beach, has lately fitted up in his waiting rooms at the eastern or Paston-place end of the line, a very interesting novelty in the shape of a giant microscope, for public exhibition each day at a small charge. The apparatus consists of an ordinary magic lantern, with a microscope attachment in front; with this difference, that the light, instead of being supplied by a lamp or oxy-hydrogen process, is obtained by the introduction into the lantern of a powerful electric arc light with an actual power of about 700 candles. By this means, objects fixed on microscope slides may be thrown upon a white sheet, and magnified to the extent of some fifteen hundred diameters. The enlargement which is effected in a 6ft. disc may be understood when it is stated that a small pin appears 2ft. thick on the disc, with a correspondingly big head; while such interesting objects as a bee's sting, a fly's eye, a spider, the down from a moth's wing, &c., are equally well displayed. Mr. Volk proposes to give short exhibitions each time the electric car arrives from the Aquarium; and it is to be hoped that his latest venture, which is already open to public inspection, will meet with success.

RECKENZAUN'S TRAMCARS IN BERLIN.—We have received a number of Berlin newspapers giving accounts of the trial trips made with Reckenzaun's tramcar, built for Mr. G. A. Plewe, of Berlin. As we mentioned last week, success is assured for this enterprise, and the following, taken from the *Berliner Boersen Courier*, shows conclusively in what light the Germans look upon the future of electrical propulsion of tramcars:—"Many trial runs have taken place of the electric tramcar (Reckenzaun's Patent), built for Mr. G. A. Plewe, Berlin. Another trip has taken place to-day from the Exhibition to the Lehrter Station. The experiences gained are extremely favourable to the new system, and influential circles are in hopes that this electric system will be introduced on most of the routes of the Great Berlin Tramway Company. As a consequence of this, a large business has been done on to-day's exchange in the shares of the Great Berlin Tramway Company which have risen in value more than one per cent." We are informed that the authorities and the police are well satisfied with the exhibition, and have given their consent for the use of electric tramways in the Berlin streets. Great interest seems to be taken in these electric trips on the part of the general public at Berlin, and among the gentlemen mentioned as having taken part we note the Right Honourable Lord Thurlow, Baron Richthofen, Captain Albert, Vogel, &c.

ANOTHER WONDER.—A German explorer, one Dr. Kümmel, has discovered, it appears, an electric tree, the *Elsassia Electrica*, in New Guinea. He proposes to chop it into slices and set up a central station for lighting by solid generators. The following description is given of the find:—"I stopped under a large tree which seemed particularly to attract the attention of Kümmel, who had been finding all kinds of novelties the whole morning, to take the exact bearings of a high peak, which was visible through an opening in front of us. To my surprise, the compass seemed utterly drunk. Whilst Kümmel and I were discussing this phenomenon one of the men struck with a *machete* one of a number of peculiar buttresses, which ran up the outside of the tree, splitting off a large slice and severing a curious looking black core, which formed the centre. Kümmel placed his hands on the two ends of the core to look at it more closely (rational action), and instantly gave a yell and rolled head over heels, getting up without his spectacles, and stammering that he had had a severe electric shock (say, 150 volts!!!)." The expedition did not possess a galvanometer, but an apology for one was made with a helix of copper wire and the compass, the result going to show that a strong current was passing through every portion of the tree. A forest of these trees was seen; the locality being nearly bare of other vegetation. The black core, we are informed, is composed of pure amorphous carbon! Here is a chance for another boom!

STEALING ELECTRICITY.—A contemporary gives an account of a new industry that has seemingly sprung up amongst the light-fingered gentry of America. It appears that the leakage to the earth of the underground leads of the Edison electric lighting system from the central lighting station in New York, U.S., is to be about three amperes, the tension being 110 volts. It was found that numerous unprincipled persons had availed themselves of the opportunity to steal electricity—an offence surely unknown to statute law—and use it for operating motors, and for induction coils. The method of filching the electricity was by boring through the iron pipe surrounding the insulating compound, and then further into one of the copper leads; a set screw fixed into this orifice, formed one connection, and the earth the other. Of course this connection was made beyond the electric meter. It was hardly worth while to maintain the continuous *espionage* necessary to detect and punish these pilferers, but the superintendent of the station, Mr. Chamberlain, coupled in extra dynamos and threw as great an increase of current over the system as the safety catches would permit, at various times. For about one second while this current was passing the incandescent lamps would give an unwonted glow, and every induction coil and motor surreptitiously attached to the system would receive an extra current designed to burn it. In this manner the system is occasionally cleared of all trespassers.

THE TELEPHONE AT WINDSOR.—At the last monthly meeting of the Windsor Urban Sanitary Authority Mr. Simpson attended, and asked for their co-operation in laying a telephone under the following circumstances:—He said he wished to have a telephone to connect his house with his farm, and he had applied to the Post Office to know the cost, and they gave him the cost of laying and maintaining at £33. 5s. a year. That seemed to him a large sum of money, inasmuch as the Post Office had a telegraph wire laid the whole distance. He had since been in communication with the South of England Telephone Company, and they offered to do it for £18, either

Digitized by Google

party to terminate the agreement by three months' notice. He then ascertained from the company that they would place the wire to Datchet and Old Windsor for £40, divided between four. The company reckoned upon going by the South Western Railway, but if the Sanitary Authority or the Board of Guardians came in it would be made advantageous for them if the line went the other way. At any rate the company's representatives were looking over the ground then, and the chairman said the cost would be £60, then £50, and he (Mr. Simpson) dare say that meant less. The authority would remember that telegraph communication with Ham was one of the things recommend by Mr. Hawksley. If they would pass a resolution authorising the Mayor to incur an outlay not exceeding £10 per annum, there might be a probability of getting the matter in hand at once.—The Surveyor said it would be a very good thing; but if they decided to have a telephone it would be better to put one up themselves, and not rent one from a company.—The matter was then referred to the Health and Drainage Committee.

Technical Education in New South Wales.—A technical college has been established in Sydney under the direction of the Board of Technical Education. The course of studies for the students, and system of instruction adopted, is practically similar with that employed by the City and Guilds of London Institute. The college contains thirteen departments, viz. :—Agriculture, including agriculture, botany, and veterinary science. Applied mechanics, including mechanical drawing, naval architecture, and metal-plate working. Art, including practical plane geometry, practical solid geometry, perspective model drawing, freehand drawing, &c. Architecture, including carpentry and joinery, masonry, bricklaying, carriage-building, plumbing, and cabinetmaking. Geology, including mineralogy and mining. Chemistry, including laboratory instruction in practical and theoretical chemistry and metallurgy Commercial economy, including French, German, Latin, arithmetic, book keeping, caligraphy, and correspondence. Mathematics, including civil engineering, surveying, navigation, and actuarial science. Music, including class singing and instruction in theory, harmony, composition, &c. Elocution, including art of public speaking and reciting. Pharmacy, including *materia medica* and pharmacy. Physics, including natural philosophy, optics, sound, electricity, and telegraphy. Domestic economy, including cookery and household management. The number of students in the college classes amounted last year to 2,128, and at the annual examinations of the Board 590 attended for examination, and 350 passed. The instruction given is of a very high order, and has been productive of excellent results. The fees are exceedingly low, so as to give every opportunity to young men of obtaining a thorough technical education.

The Inter-Continental Telephone Company.—This company is organised under the laws of the State of New Jersey, and has acquired all the telephonic rights, franchises, and property formerly owned by the Tropical American Telephone Company, in Venezuela, United States of Colombia, Panama and Central America. The company has secured a concession from the Government of Venezuela, giving it the exclusive right to establish and maintain telephonic lines and exchanges in and between the cities of Venezuela, and has already in full operation an exchange in the chief city, Caracas, with 475 paying subscribers. At La Guarya, the chief port of entry to the country, there is also an exchange, with about 100 subscribers, and the two cities above-named are connected by a trunk line with four wires, giving the subscribers of both places instant telephonic connection with each other. There is also a similar system at Valencia and Porto Cabello, cities of next importance in Venezuela, with trunk line between them, and 150 subscribers are already secured at Valencia and 125 at Porto Cabello. It is proposed to establish similar systems at Maracaibo, Barquisimeto, Bolivar, Barcelona, and the other cities of Venezuela wherever 50 or more subscribers can be secured. In United States of Columbia a sub contract has been made with The Columbia and Panama Telephone and Telegraph Company, which latter, organised under the laws of the State of New York, with a capital of 100,000 dollars, is doing the telephone business in Columbia and Panama. Exchanges have been established at Bogota, Barranquilla and Carthagena, and others will be commenced wherever a sufficient number of subscribers can be secured to support a central office. In Central America a contract has been entered into with Messrs. Wendell and Phillips, of Boston, giving to them for a term of years the exclusive right to export from the United States and sell, lease, and use in that territory Bell and Blake telephones and transmitters. At Guatemala city an exchange has already been established with 200 promised subscribers, and opportunity is offered for the establishment of central office systems at other cities in Central America.

The Tropical American Telephone Company.—This company, organised in November, 1881, acquired from the Continental Telephone Company of Boston (the assignees of Prof. Alexander Graham Bell, Francis Blake, Watson, Anders, Roosevelt, Fuller, *et al.*) all telephonic rights formerly its property in Central America, United States of Columbia, Venezuela, British, Dutch, and French Guiana, Chili, Peru, Ecuador and Bolivia, South America, and all the West India Islands, except Cuba (already ceded to the Cuban Company). By subsequent purchase it obtained from the Continental Telephone Company all its existing telephonic rights in Brazil and the remaining countries of South America, including valuable contracts with subsidiary companies; and now has the sole and exclusive right to sell, lease, and use "Bell" telephones, "Blake" transmitters, and all other telephonic apparatus manufactured by the American Bell Telephone Company, under patents owned or controlled by it in the United States and Canada, in the entire territory of South America, Central America, and West Indies, named below, and is the source of supply for telephones, transmitters, telephonic instruments, and supplies to the following telephone companies, already organised and doing business, viz. : — The Inter-Continental Telephone Company, controlling Central America, United States of Columbia and Venezuela; the West India Telegraph and Telephone Company, controlling Jamaica, Porto Rico, Hayti, San Domingo, &c.; the Columbia and Panama Telegraph and Telephone Company, controlling United States of Columbia and Panama; Companhia Uniao Telephonica do Brazil, successor to the Companhia Nacional de Electricidade and Companhia de Telegraphos Urbanos, operating in Bahia, Pernambuco, Para, Santos, Campinas, and elsewhere in Brazil; Companhia Telephonica do Brazil, operating in Rio de Janiero and Nictheroy, Brazil; West Coast Telephone Company, controlling Chili, Peu, Ecuador and Bolivia; the Commercial Telephone Company, Limited, controlling the Island of Trinidad, West Indies; the Barbados Telephone Company (Limited), controlling the Island of Barbadoes, West Indies. The Tropical American Telephone Company established exchanges in Barbados and Trinidad, West India Islands, and sold the business and plants to the last two companies, and will continue to supply the private line and exchange telephone business throughout the entire territory now under its control.

THE STEAM ENGINE INDICATOR.—XIII.*

BY AMICE.

The hyperbolic curve of expansion is often called the isothermal curve of expansion, because a gas such as air gives this curve when it expands from one volume to a larger volume, providing that the thermal conditions remain the same. The pressure of such a gas varies inversely as the space it occupies only so long as the temperature remains constant. Thus a curve representing the fall of pressure of a gas as inversely proportional to its volume represents that pressure when and only when the expansion takes place in a vessel in which the air is maintained throughout the whole period of expansion at the same temperature, or when it takes place isothermally. Now, it only happens, that under ordinary conditions of working in well made steam engine cylinders, the curve of pressures of the expanding steam very nearly follows this hyperbolic curve or so-called isothermal curve. It must be remembered that, with respect to the expansion of steam, it is not an isothermal curve, inasmuch as the temperature of steam in any cylinder falls during expansion. Thus, with steam at 75lb. absolute, *i.e.*, including the pressure of the atmosphere, expanded down to a pressure of 5lb. absolute, the temperature falls from 307·5deg. to 162·4deg. The hyperbolic curve does not, therefore, represent isothermal expansion of steam, as that cannot take place; it only approximately represents the relative pressures and volumes of expanding steam.

As a means of obtaining the mean pressure throughout the stroke when a diagram cannot be taken, or for estimating the probable indicated horse-power of an engine of given dimensions, steam pressure, and cut off, a formula based on Boyle's law, and containing a hyperbolic logarithm, is used, and is as follows:—

$$p = P \times \frac{1 + H}{R};$$

p being the mean pressure;
P the initial pressure;
R the range of expansion.
H the hyperbolic logarithm of R

Thus for a pressure of 75lb. absolute cut-off at one-fourth the stroke, or in other words used with a range or ratio of expansion of 4, for which the hyperbolic logarithm is 1·386, we have $p = 75 \times \frac{2·386}{4} = 44·7$lb. per square inch as the mean pressure.

In the steam engine cylinder, if of a condensing engine, this will be lessened by the imperfect vacuum, or by the back pressure. This will vary in different engines, but is seldom less than from 3lb. to 4lb.

The mean pressure thus obtained is the same as that given by a hyberbolic curve, and it must be remembered that the steam admitted to fill the clearance and port spaces must be taken into consideration. The power of the engine during the steam admission period is not affected by this amount of steam, but the total mean pressure throughout the stroke is increased by it. Thus, in the above case, when the clearance steam is taken into account, the ratio of expansion is lessened, while the period of steam admission and the stroke remains the same, a condition not easily taken into the calculation, though very easily measured on a diagram. It is clear that the pressure is maintained at a higher pressure than it would be during expansion were it not for the steam so admitted, and we can only take it into the calculation by allowing for its volume, and assuming a smaller range of expansion. For instance, in the above case, if the clearance represented a volume equal to one-eighth the capacity of the cylinder, then, instead of the ratio of expansion being $\frac{1}{4}$, or $\frac{2}{8}$, it would be $\frac{3}{9}$, or R would be 3, but the work done would not be in proportion to this, as the full pressure steam would not have effect on the piston during more than the $\frac{1}{4}$ stroke.

The difficulty is that by adding the amount of the clearance to the steam admitted to the cylinder before cut-off we charge the piston with a greater duration of full pressure than it actually has, for the steam admitted to fill clearance spaces does no work during admission, yet we must credit it with doing work during expansion. The only possible way of calculating the mean pressure throughout the entire stroke is thus to take the whole of the steam admitted, and after obtaining the mean pressure from this, to deduct the amount of work that would be done by the steam admitted to fill clearance, if it were admitted during the movement of the piston instead of before it. Thus, taking the above case, the mean pressure, the hyperbolic logarithm 3 being 1·098, will be $75 \times \frac{1 + 1·098}{3} = 52·4$. This is the pressure during the whole length of the cylinder, including clearance as part of the cylinder, assumed as above to be nine units of length. But the piston is not able to make any use of the pressure existing the first ninth of the cylinder, this part or ninth being the clearance. This amount must then be credited to the piston. It may be thus done as a comparative example:—

Total pressure throughout cylinder and on unit area	=	$52·4 \times 9 = 471·6$
Less ineffective pressure during admission	=	$75·0 \times 1 = 75·0$
Total pressure throughout stroke		$= 396·6$
Mean pressure throughout stroke of piston	=	$\frac{396·6}{8} = 49·57$

This is not absolutely accurate, but it is sufficiently accurate for all practical purposes. It shows how very important a part clearance may play, not only in explaining the much higher pressure which is found in cylinders during expansion than would be obtained were it not for the steam used in filling clearance spaces, but it shows how large a quantity of steam may be lost by clearances when sufficient compression is not employed, or when it cannot be employed. It will also be seen that the effect of clearance is greater with high pressures and early cut off or long ranges of expansion than with low pressures and small ranges of expansion. We need not follow this with reference to adiabatic expansion, as this, though of importance in theoretical investigations, is not so in practice.

If steam is expanded in a non-conducting cylinder, and neither receives nor loses heat by conduction or radiation, it is said to be expanded adiabatically. In this case the pressure falls in proportion to the amount of work done by the piston. If the work done is 772 foot-pounds, then the thermal equivalent of this, namely, one unit of heat, is abstracted from the steam, and the pressure falls in proportion to that one unit. At least, this is assumed to be the case, and although there is no direct experimental proof that the performance of work of itself causes the abstraction of heat, it is reasonably assumed that this is the case; and as a large quantity of heat is lost, it is assumed that this is one of the sources of loss. In as much, however, as non-conducting and non-radiating cylinders do not exist, the curve which represents adiabatic expansion is not of much importance in this connection. We are not, however, clear that adiabatic compression or an approach to it does not occur when considerable compression is employed. Under adiabatic conditions the pressure, according to Rankine, varies nearly as the reciprocal of the tenth power of the ninth root of the space occupied, or P being pressure, $P \propto \frac{1}{v}^{-\frac{10}{9}}$. To find the pressures from Rankine's formula involves a good deal of calculation, but a table of constants is given by Mr. Northcott in his work on the steam engine, which facilitates the calculation, and from this we may take a few figures, obtained by the formula $\frac{p}{P} = \frac{10 - 9r^{-\frac{1}{9}}}{r}$, p being the mean pressure. (Table A.)

To find the mean pressure exerted through the stroke when expansion takes place under these conditions it is only necessary to multiply the constant opposite the ratio of expansion. Thus, dry steam at 75lb. per square inch expanded adiabatically from one volume to four volumes will give a mean pressure of $75 \times 0·571 = 42·82$lb. The loss of pressure as compared

* For Art. 12, see *The Electrician*, 18th December, 1885.

with steam expanded in a jacketed cylinder is thus 44·7 – 42·8 = 1·9lb.

TABLE A. ADIABATIC EXPANSION.—*Constants for Mean Pressure.*

Ratio of Expansion	Constant.	Ratio of Expansion.	Constant.	Ratio of Expansion.	Constant.	Ratio of Expansion.	Constant.

2·5	0·748	4·5	0·529	6·5	0·414	8·5	0·341
3·0	0·678	5·0	0·495	7·0	0·393	9·0	0·327

An adiabatic curve of expansion may be constructed by taking out any number of final or terminal pressures—that is to say, pressures at any number of given ranges of expansion, as follows. The terminal pressure with adiabatic expression will be

$$p' = \frac{P}{R^{\frac{10}{9}}}.$$

For example, we may take the following diagram, Fig. 42, which is the same as Fig. 39, page 68, but with the dotted curve added, showing the curve of expansion when adiabatically effected. In this diagram A B C D represents the unit

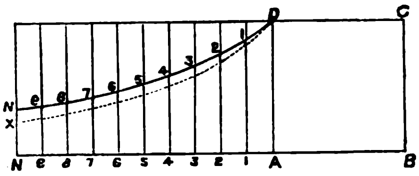

FIG. 41.

volume admitted before cut off. Estimating the pressure at the line 2-2, that is after expansion has increased the volume from 1 vol. to 1·4 vol., each of the spaces on this diagram being = 0·2, or two-tenths of the volume represented by distance A B, and taking the initial pressure as 63lbs. as before, we have $p' = \frac{P}{R^{\frac{10}{9}}} = \frac{63}{1·4^{\frac{10}{9}}} = \frac{63}{1·45} = 43·4$ lbs.

In this way we may get the pressures at any number of points.

Taking our diagram they are on the ten pressure or pressures at D, &c. :—

D,	1,	2,	3,	4,	5,	6,	7,	8,	9,	N.
63,	51·6,	43·4,	37·38,	32·8,	29·1,	26·2,	23·8,	21·8,	20·2,	18·5.

The several pressures being set off as ordinates we get the adiabatic curve D, X, which is below the hyperbolic curve D N by the amount which the steam pressure would lose if it were expanded in a perfectly non-conducting cylinder.

The following figures give terminal pressure ratios for a few ranges of adiabatic expansion, or $R^{\frac{10}{9}}$.

Ratio of Expansion R.	Adiabatic Ratio $R^{\frac{10}{9}}$.	Ratio of Expansion R.	Adiabatic Ratio $R^{\frac{10}{9}}$.

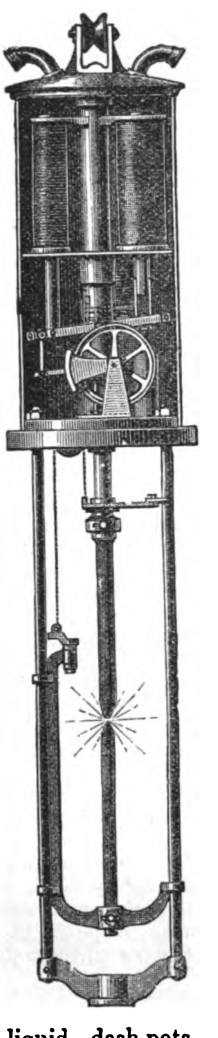
DYNAMO TESTS.—The results of the dynamo tests at the Philadelphia Exhibition, as published in the report issued by the Franklin Institute, will be reprinted in an early issue.

THE BROCKIE-PELL ARC LAMP.

The accompanying illustration shows the present form of this lamp, the principle of which is essentially different from others of the direct-acting class. Nearly all such lamps are regulated by the differential action of two coils, one being in the main circuit and the other in a branch or shunt across the arc. This combination necessitates the main coil being made more powerful than the shunt, and therefore any change in the main current very readily and considerably affects the regulation.



In the Brockie-Pell lamp it is claimed that the two coils are so peculiarly related to each other that the main coil may be of very much inferior strength to that of the shunt coil, and therefore much greater variations in the main current may take place without unduly lengthening or shortening the arc; thus a steady light is obtained even with a variation in the main current of 25 per cent. above or below the normal or working current. The lamp may be briefly described as "semi-differential," because the main coil plays a smaller part in the regulation than in purely differential lamps; in fact, the main coil is only made powerful enough to separate the carbons and obtain the arc, the shunt coil coming into operation afterwards and playing the leading part in the regulation.

The mechanism is simple and strong, and is calculated to withstand considerable rough usage. The adjustment is effected by means of weights, which cannot alter, and, when once adjusted to the normal working current, the lamp is said to work well without any other attention than the usual cleaning of the sliding rod, which must not be neglected in any arc lamp. There are no trains of wheels, liquid dash-pots, regulating springs, nor make-and-break contacts, and the working parts have been reduced to the lowest possible number. As a proof of the perfection in the feed of this lamp, the makers (Messrs. Johnson and Phillips) give the result of an experiment recently made—viz., a very delicate Thomson mirror galvanometer was placed in a shunt circuit across the arc whilst the lamp was burning, and the variation in the range of the spot of light on the scale did not exceed 10 divisions in 300.

OBITUARY NOTICES.

CAPTAIN SIR FREDERICK J. O. EVANS, R.N., K.C.B., F.R.S.

Captain Sir F. J. O. Evans, late hydrographer of the Admiralty, died on Sunday last at his residence, 21, Dawson-place, in his seventy-first year. The deceased officer entered the Navy in the year 1828. In 1855 he was appointed superintendent of the Compass Department of the Admiralty, at a period when the science of terrestrial magnetism in relation to iron ships was in its infancy; he was at this time a mathematician of no mean repute, and sagaciously foreseeing the important part this abstruse science was destined to play in the Navy, now being revolutionised by the change from wood to iron, he devoted his whole energies to the study of the subject until he had made himself completely master of it. In conjunction with that accomplished mathematician, the late Mr. Archibald Smith, F.R.S., he published, in 1869, the "Admiralty Manual for Ascertaining and Applying the Deviation of the Compass," which was translated by all maritime nations, and has been the accepted text-book in our own and other navies up to the present time. In 1865 Captain Evans was appointed chief assistant to the hydrographer, retaining also

Digitized by Google

his position as head of the magnetic department. In 1874, a vacancy occurring for the post of hydrographer, he was appointed to fill it. He had enjoyed the cordial friendship, esteem, and entire onfidence of the three officers who had preceded him, and no more proper or worthy selection could have been made. He continued to perform the important duties of this office with great ability and conscientiousness until within little more than a year of his death. Sir F. Evans was elected a Fellow of the Royal Society in 1862, and served for many years on its council, and was more than once a vice-president. He was nominated a K.C.B. in 1881.

THE LATE MR. GEORGE HENDERSON.

The late Mr. George Henderson was born at Borrowstounness, County of Linlithgow, on the 4th of December, 1813, having at the time of his death just entered his seventy-third year. He was educated at the School of Dollar, in Clackmannanshire, and when a very young man moved with his father, Mr. George Henderson, a shipowner, to the port of Liverpool. The style of his father's firm, which was founded by his grandfather, was Robert Henderson and Sons, of which, with his brother, the late Mr. Robert Henderson, of Mincing-lane, he eventually became a partner. While continuing a partner of his father's firm he joined the members of a Calcutta house, who were the correspondents of his late uncle's firms, Messrs. R. and J. Henderson, of London and Glasgow, and moved his place of business from Liverpool to London. The firm in Calcutta, of which at the time of his death he was the head, is George Henderson and Co., and in London George Henderson and Sons. Mr. Henderson was mainly instrumental in developing the jute spinning industry in India, showing for the first time (which had been doubted) that the natives of Bengal were capable of being converted into useful factory operatives. With the assistance of Mr. Thomas Duff, he founded the company, for some time carried on as a private enterprise, and which was afterwards converted into the Barnagora Jute Factory Company (Limited), and in conjunction with his partner, the late Mr. Herbert Knowles, introduced into Bengal the manufacture of paper by machinery. Mr. Henderson took a warm interest in the progress and consolidation of the India Rubber, Gutta Percha, and Telegraph Works Company (Limited), of which he was for many years the honoured chairman, and he was also a director of the Borneo Company (Limited). He expired at his residence, Heverswood, parish of Brasted, Kent, on the 11th inst., having been absent from business only six weeks. His remains were interred in the family vault, in the churchyard of Sundridge, and were followed to their last resting place by a large assemblage of sorrowing friends. In public life he was much respected, and as the funeral *cortége* passed through the village every house was closed.

MAGNETISM.

BY WILLOUGHBY SMITH.

Let it be assumed as correct, it not being of the slightest importance for my present purpose whether it be so or not, that a Greek shepherd, Magnet by name, whilst tending his flock on Mount Ida, found that there were in parts of the earth around him peculiar hard substances, from which, if he placed his iron crook upon them, he had difficulty in detaching it. Neither is it, at this time, of material importance to know the date of this discovery; but it may be noted in passing that it must have been a very long time ago, as Homer, Pythagoras, Aristotle, and other celebrated men of their time mention it in their writings. It is even asserted that Thales, the most ancient philosopher of Greece, was acquainted with the attractive power for iron possessed by the substance called magnet, this name being given to it, I suppose, with the view of perpetuating the name of the discoverer of what must have seemed in those days a supernatural phenomenon.

It does not, however, appear that these ancient philosophers attempted to gain knowledge by experimental research, although they were such close observers of nature and its workings. No doubt the discovery of so strange and wonderful a phenomenon was a subject for much learned discussion and disputation in their schools of science; but they had not realised the important fact that theory and experimental research should go together, for useless is the theory that cannot be supported by experience, and experience, without some theory of generalisation and arrangement, would be nothing but a confused mixture of facts. Had this been more fully recognised it is possible that the most important property of the magnet – its directive force—would not have remained so long undiscovered. For it is recorded that it was not until the thirteenth century that it became known, at any rate in Europe, that when a magnet was freely suspended it turned one and always the same part of its surface towards the north pole of the earth, or a point not far from it; the opposite part of its surface, of course, pointing south; these parts were then termed poles.

When this directive force was practically applied to navigation and similar purposes, the magnet became more generally known as the "loadstone," a word said to be derived from a Saxon term signifying a "guide."

The magnet or loadstone is an oxide of iron of a dark grey or dark brown colour, found in almost all parts of the world, generally in irregular pieces of a few inches in dimension, although pieces have been found weighing over 100lb., and capable of supporting by suspension pieces of iron of double their own weight. It doubtless was soon observed that the directive force of these stones was very capricious, owing to the extraordinary difference in various parts of the same stone; for while one part would attract another would repel the same substance. This difficulty was surmounted by the discovory that by placing a plate of iron on each end of the stone, all the power of the stone appeared to centre itself in those iron plates and to give strong and uniform directive power. After the application of the iron plates it must soon have been observed that they, more or less, retained the property of the stone after their detachment from it, and that the harder the iron the more lasting was the effect. When the knowledge was fully recognised that the directive and attractive power of the stone could be imparted, without loss to itself, to hard iron or steel and permanently retained thereby, magnetised bars, or needles as they are now called, superseded the loadstone for ship's compasses and other like purposes, and the term magnet was again more generally applied. At the present time the word "loadstone" is very seldom if ever used, unless in application to the stone itself.

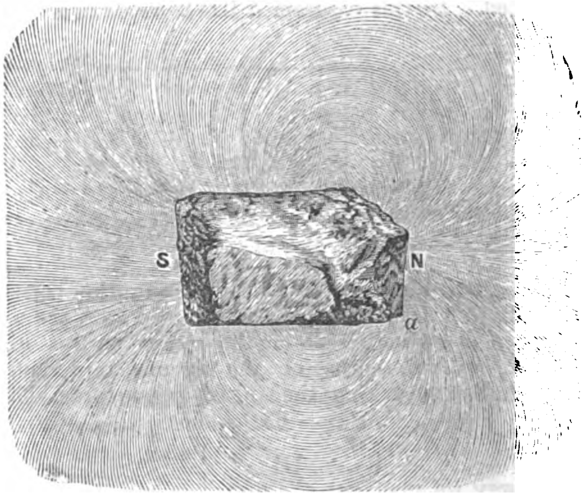


Diagram I. represents a natural magnet or loadstone which I have in my possession. It is a magnetic iron ore of a specific gravity of 4·9, and, according to Bloxam, this variety of ore contains about 72% of iron. Its weight is 17,730 grains, but its attractive power is very slight, owing to its possessing what may be termed so many points of action, as represented in the diagram. The attractive power at many of these points is scarcely perceptible; the strongest point is marked *a*, and even there it will only support 17 grains of iron. But it will sustain a plate of iron weighing 1531·25 grains, if the iron be of sufficient surface to cover the whole of the base; and if the iron be extended so as to cover the two ends also, its attractive power will be increased to 24,062·5 grains. Taking the soft iron end pieces separately, while in contact with the stone, their respective attractive power is

North..	2645 grains.
South..	2437·5 ,,

If one of the soft iron pole pieces be applied to different parts of the stone, then, as far as it is possible to ascertain, where any considerable attraction takes place between the stone and the iron, very little free magnetism is shown by the latter; but if no attraction exists between them free magnetism is manifested at the end of the iron. I cannot tell when this stone was first used for experimental purposes, but, forming my opinion from the antiquated character of the engravings on the brass case in which it is mounted, I should say it was at least three hundred years ago; and, if I correctly interpret the engraved figures, its strength has since that time decreased more than fifty per cent. Writers on the properties of this class of ore or stone have frequently expressed their astonishment at the way this power, which we call magnetism, exists naturally in them. Even Faraday has said that "The way in which it exists at all times in a stone like this is the most remarkable fact connected with magnetic force." Whenever giving thought to the subject I always imagine the earth as one huge loadstone, and consequently look upon it in the same way as upon the small stone, the properties of which I have just given; for if the world could be experimented with in

Digitized by Google

precisely the same way, similar results would be obtained, the only difference being the high attractive and directive power of the one over the other, owing to the vast difference in their dimensions.

This would be analogous to experiments carried out with a huge magnet and a very minute portion of the same, for similar magnetic effects would be obtained in each case, but the difference of the intensity between the two would be very great. Astronomers consider the world an oblate spheroid body, elevated at the equator and depressed at the ends, and, for convenience, they imagine a line passing through its centre, and the extremities of this imaginary line they term the poles.

Now at or near the place of these imaginary poles the earth has its strongest attractive magnetic power; consequently, proceeding from these two points are strong magnetic curves lines of force, which, by their polarisation effects, cause the atmosphere surrounding the earth to be one whole magnetic field. To what height those curved lines extend it is impossible to say, for we can only positively assert that the boldest aeronaut has not yet ascended beyond their influence.

When experiments in magnetism are being made, it should be constantly borne in mind that the work is being done in an atmosphere of magnetism, the lines of force of which vary in intensity according to the position on the earth at which the experiments are made; and not only the position, but also the time and temperature.

If this be really the state of the planet on which we dwell, may it not be probable that the other planets, which are said, like this world, to be "swimming" in the medium of space around the sun, each one being surrounded by its own atmosphere, are similarly affected; and that polarised magnetic lines of force are the means employed by the great Architect of the universe (who, as far as our limited knowledge extends, employs no rectilinear motions or angles, but all motions created by Him are performed in curved lines) to bind together and control the whole system.

> "See plastic Nature working to this end
> The single atoms each to other tend.
> Attract, attracted to, the next in place
> Formed and impell'd its neighbour to embrace.
>
> * * * *
>
> All served, all serving, nothing stands alone.
> The chain holds on, and where it ends unknown."

Having discovered the attractive and directive power, and the dip of the magnet, it appears to have been assumed that the whole subject was exhausted, as very little more attention seems to have been given to it, until Dr. Gilbert, in the year 1600, published his original treatise on the magnet. This created quite a new and enthusiastic interest in the subject, especially his hypothesis of terrestrial magnetism, in which he assumed that the earth contained within itself a powerful magnet, lying in a position nearly coinciding with its axis of rotation. Some of the enthusiasts of the day accepted this hypothesis as correct, and looked upon it as one of the greatest discoveries in the annals of science, whilst others propounded new theories which as fully illustrated how erratic is the unbridled imagination, especially when it has overleaped the bounds of reason. Although the advancement of knowledge will not allow of the correctness of many things recorded by Gilbert and other writers of his time, yet it may be still admitted, with truth, that Dr. Gilbert did much to increase our knowledge, and that he is justly termed "the father of the science of magnetism." The magnetic effects which were observed to be produced by lightning—Franklin's discovery of the identity of lightning with electrical discharges artificially produced; and the effects produced on magnetic needles by the aurora borealis, combined with the facts that similarly electrified bodies repel each other in the same way as those bodies which are similarly magnetic, and that dissimilarly electrified bodies will attract each other in the same way as those bodies which are dissimilarly magnetic, encouraged philosophers in their endeavour to identify the electrical and magnetic powers as one and the same. Powerful currrents from large electrical machines, or from batteries formed of large Leyden jars, charged to their highest tension—the only known means in those days of generating and accumulating electricity—were passed through bars of steel or iron of all forms and under all conditions; but the results obtained were very slight and capricious, and showed no advantage over the magnetic effects usually produced by a blow given to a bar of iron from any mechanical action. Father Beccaria, a celebrated Italian philosopher, concludes his experiments in this direction by asking "Are not these peculiar effects of this electric *fire* with respect to magnetism so many proofs which corroborate my former conjecture, that the peculiar magnetic force observed in *loadstones* is to be attributed to either atmospherical or subterraneous strokes of lightning, and that the universal systematical properties of magnetic bodies are produced by an universal systematical circulation of the electrical element?" These remarks of Beccaria's do not appear to have attracted much attention at the time, but fifty years afterwards Ampère suggested a similar theory which attracted much attention; but then Ampère had had the advantage of two most remarkable and important discoveries which had been made since Beccaria propounded his theory.

It has often been found that experience produces facts which the wildest imagination never conceived even in its dreams. Bold, if not absurd, would have been considered the flight of imagination of the romancer who compiled his work from such incidents as those which belong to the history of Volta electricity. For instance, in 1790 an Italian lady slightly indisposed was advised by her physician to partake of some frog broth; her husband being an anatomist, at once proceeded to prepare the frogs, and while so doing observed that the disconnected limbs became convulsed with movements resembling vital action whenever they were touched at the same time with any two dissimilar metals, iron and copper for instance.

The important results which have sprung from this simple incident illustrate the beautiful and unerring laws of nature developed under the most simple conditions, but which are too often, on that account, unheedingly passed by. This strange and startling phenomenon led to experimental research; and had Prof. Galvani been more of an electrician, he probably would not have adhered so tenaciously to his theory of animal electricity. The results of Volta's experiments led him to assert that Galvani's theories were incorrect, and that the phenomenon was not due to animal electricity but simply to a current of electricity emanating from the surface of contact of two metals; but Prof. Fabroni discarded both the preceding theories, and experimentally demonstrated that electricity was generated by the decomposition of the moisture lying between the two metals.

Each of these three hypotheses had their own partisans, but the controversy as to the origin of galvanic electricity, as it was then called, somewhat abated when, in March, 1800, Volta announced his discovery of the voltaic pile, composed of a combination of alternate discs of copper, zinc, and wet cloth. By this arrangement a generator of electricity was produced which gave a gentle and continuous current in large quantity, and not the sudden or instantaneous currents with uncontrollable and irresistible violence which had hitherto been obtained. From this discovery, commenced the most splendid era in the history of electricity; it supplied experimentalists with a new implement for electrical research, amongst the foremost users of which was Sir Humphrey Davy, who, although a young man of only twenty-one years of age, not only put beyond doubt the fact that chemical action is essential to the vitality of the voltaic pile, but showed different methods of generating currents, and thus localised sufficiently for all practical purposes the "seat of electromotive force in a voltaic cell." A few years afterwards he published that most important discovery of the decomposition of fixed alkalies by currents of electricity generated by chemical action, and of the metallic nature of their bases, thus founding a new science of electro-chemistry. These discoveries burst so suddenly and unexpectedly upon the scientific world as to cause great wonder.

Electro-magnetism was again eagerly sought for, this time by the aid of the voltaic pile, and, after twenty years of labour and thought, the experiments of Prof. Oersted carried him victorious to the desired goal; for he then discovered that an electric current, traversing a metallic wire joining the two poles of a voltaic battery, will deflect an adjacent magnetic needle from its natural direction; and that, in the absence of interfering forces, the latter would be placed at right angles to the former, thus demonstrating, by actual experiment, that an electrical current communicates magnetic properties, by induction, to such bodies in the vicinity as are susceptible of acquiring them. Prof. Oersted thus proved that there exists a reciprocal action between electric currents and magnetic bodies, and this was the foundation of the whole science of electro-magnetism. The discovery of the magnetic properties of electrical currents was at first received throughout the world with unqualified astonishment, as all previous attempts to identify electricity and magnetism had been unavailing. It was soon ascertained that Prof. Oersted had opened a new field of research, and its fertility was manifested by the great variety of interesting facts speedily brought to light by the emulative labours of experimenters; in fact, so rapid was the development of discovery in this new field of Oersted's that it was very difficult, if not impossible, for those whose attention could not be exclusively devoted to the subject to keep pace with its progress.

With the knowledge of Oersted's discovery, it would naturally suggest itself to every person giving thought to the subject, that if a conductor connecting the dissimilar metals of an electrical battery possessed magnetic properties, whilst so placed, then it would be fair to suppose that all the effects which can be obtained from a magnet should be obtained from a wire so placed, and their experiments would naturally be in that direction.

(To be continued.)

A SCIENTIFIC PROFESSION.

Judging by the numerous inquirers who have lately invaded our privacy, we are led to believe that a fresh trouble has overtaken the heads of families at this trying time of the year. Young men are coming home, many of them for the *very* long vacation—that is to say are leaving school for good, and are eligible for situations comparatively few in number, and the candidates for which are extremely plentiful. Education is no longer a scarcity in the market; and, added to those ailments which afflict us at Yuletide, commonly classed under the generic term Christmas-Bill-iousness, there has set in a new malady which, with similar levity, might be called Son-stroke, whereby the parent is mentally incapacitated from discovering any suitable employment for his male projeny. We say mentally, because in point of fact there are just as many facilities for obtaining good work as there ever were, in some respects more; the new difficulty being we suspect very largely, though not, perhaps, wholly, due to the higher views which have latterly come into vogue with regard to what constitutes good work, and what is derogatory to the dignity of a well-born and well-educated youth. A respectable and rather high-priced magazine has actually been started exclusively in the interests of the afflicted father, describing in glowing detail the advantages of the several careers open to the sons of gentlemen in this country. These careers are of course all professional, all requiring a liberal education, and some of them commanding wages almost as good as those of a skilled mechanic. They are highly respectable, moreover, and this of itself seems to be the chief attraction for the distracted father of the period.

With the opening up of brilliant prospects for Electric Lighting industry there naturally arose an enthusiasm for scientific teaching never before exhibited, in order that the rising young man might qualify to enter upon this new and lucrative career. And, notwithstanding the many disappointments it has encountered, "Electric Lighting of the future" still possesses many attractions for the anxious parent whose sons apparently were born into the world just in the nick of time, and with no other aim than to further the progress of the new illuminant. We need not state what respectively has been the advice we have tendered in the many cases laid before us. Suffice it to say, we are not responsible for the incompetent doings of the half-trained and wholly inexperienced persons who have already contrived to shipwreck more than one undertaking which in better hands might have been examples of brilliant success. This has come about through people meddling with electricity whose knowledge was mainly confined to engineering, or who knew something of electricity but not enough of engineering. Perhaps in the then condition of the educational market these catastrophes were unavoidable. All we say is that we had no hand in them. If any of our friends have blundered into unenviable notoriety, it has been through yielding not to our advice, but to their own rash impluses.

Some appropriate remarks on this subject were made by Sir Frederick Abel when distributing prizes at the Crystal Palace School of Practical Engineering last Saturday. Contrasting the opportunities of such men as Stephenson, Fairbairn, and Whitworth with those of the modern student, he pointed out that whereas only 12 years ago, when the work of technical education had hardly begun, there were only 202 persons who submitted themselves for examination, there are in the present year close upon 4,000. This is highly encouraging; but it was appropriately added that formerly men who rose to eminence like those mentioned above had to labour like working men in the hardest sense of the term, and at the same time had to acquire that knowledge which afterwards enabled them to fill such brilliant positions in the world. The statement is even truer to-day than it was formerly. To rise to eminence in any of the professions of applied science it is necessary to stoop to toil and not be ashamed of it. Scholarship has now, as ever, an important part to play; but, contrary to what is vainly imagined by the genteel parent, it is a part which few can play to perfection, and which it would be as absurd to choose for "a profession" as to "choose" to be a genius. If the student has genius to begin with, he will develop it in a fitting direction, whether in theory or practice—possibly in both. But young men whose parents have to find out a career for them are not usually geniuses; and what they have got to do is to work up to their proposed career, which is not attained by a fastidious regard for unsoiled fingers, or a languid preference for book learning. The field of science grows wider in every age, and an acquaintance with every corner of it becomes more and more unattainable except by the rarely gifted. But a practical knowledge of any given area is possible for every one who is endowed with diligence and not handicapped by pride. The science and the theory may be had simultaneously, or subsequently, according to the individual's capacity. But for earning a living, practical knowledge is the first and indispensable requisite.

To put a young gentleman in the workshop as a beginning is about the last thing the modern parent or guardian now thinks of doing. Yet in the majority of cases it is the very

Digitized by Google

best thing to do. If the candidate is naturally studious he will be none the less so, but more healthfully so, by throwing a good spell of handicraft into the bargain. As to his character, if he is what he professes, he will not lose caste in the workshop; quite the contrary; he will be respected while there, and if successful in after life, will be more highly esteemed for having started fair with the common workman. If there is nothing uncommon in him, nothing above the average labourer, then depend upon it his mediocrity will prove less disastrous than if he were thrust into the profession higher up the ladder only to drop from it a pretentious failure. There are abundant examples of showy scientism coming to grief when put to practical test; and not a few of ludicrous failures by eminent theorists unable to realise their conceptions in practice. But the practical man, if he flies not so high, is sure of his wings, and will alight safely. The thinker will always be the pioneer of the worker, and is mentally his superior; but in selecting a profession it is safer to reckon on what a man can do than on what he may think; and a working beginning will at all events not unfit any man for the exercise of his higher faculties later on. To all of our readers, and especially to such as have the cares of a growing male family on their minds just now, we heartily wish a Merry Christmas—to which the foregoing observations may, we hope, in some degree contribute.

CORRESPONDENCE.

CURRENT INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst Prof. T. A. Smith's *confrères* are giving their criticisms on the careful and interesting experiment he recounts (p. 111), will you kindly allow me space for a few words myself. Is it not a very striking fact that the only person who has taken up this question and dealt with it face to face is Prof. Smith, at a distance of some 4,000 miles? It is because a transatlantic mind is in advance of Great Britain in its wide receptiveness for what is new, and possibly true, that the Professor grants both a patient hearing and a considered judgment to a heresy bearing some marks of serious reasoning. As to the experiment itself, it is like one which Mr. Edgar Smart carried out some weeks ago, in which, however, an iron core was used. With apparatus improvised at home I have never succeeded in making a satisfactory experiment without the intervention of iron.

There is a good deal to say and to ask about the American experiment, but considerations of space urge me to defer my remarks.—Yours, &c., E. ALDRED WILLIAMS.

37, Burlington-road, W., Dec. 19, 1885.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Amongst the "Notes" of your previous number there is one headed "In the Organic World," and you write "We have an electric plant, an electric bug, an electric slug, and three electric fishes." Why was the electric boy not included in this list? Was he not exhibited in London? He was exhibited in Edinburgh for a long time, and advertised in the newspapers. When I first saw the advertisement I considered it a trick of some showman, therefore did not go near the exhibition; but after meeting with a friend, a scientist, who had seen the boy, I went to see him. He was then exhibited in one of the small stalls in the gallery of the market in Princes-street. I found there a little black boy in charge of a white man. There was no furniture in the stall but a couple of wooden seats and a small piece of carpet to keep the boy's bare feet off the floor. There was therefore nothing wherewith to conceal any electrical apparatus. As I was at that time the only visitor I had the boy stripped naked and was satisfied there was nothing outside of his skin that could produce electricity. While thus naked he walked in my presence, and also sat on the wooden seat with his feet off the ground. In every position in which I tried him I found electricity proceeded freely from his body when I touched it with one finger. The electricity came with the greatest freedom from the upper half of his body, and especially from his tongue. Although I felt a slight shock in my finger when I touched his tongue he did not seem to feel any; his tongue did not quiver and he did not offer to withdraw it. I thereon asked him if he did not feel anything unpleasant when I touched his tongue. He replied, No! This surprised me much, because when an ordinary person is placed on an insulated stool and there surcharged with electricity and then touched by an uninsulated person, both parties feel the passage of the electricity unpleasant; but not so this boy. He seemed to be so full of electricity that the passage of it from his body gave him no more uneasiness than the passage of perspiration from him.—Yours, &c.,

JAMES JOHNSTONE.

ELECTRIC BELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In experimenting on the short-circuit method of working electric bells, I have invariably found that it produces a very much feebler motion of the hammer than the ordinary method of making and breaking the circuit affords. The construction of these short-circuit bells is given in the articles on "Pratical Telephony" (p. 189, Vol. XI. of *The Electrician*), so perhaps some of our telephonic friends can explain the reason, and the remedy if there be one?—Yours, &c., J. W. J.

Birmingham, Dec. 18, 1885.

ELECTRICITY IN WARFARE.*

The first practical plan for using electricity in warfare was devised and executed by Col. Samuel Colt, the inventor of the revolver, who, in 1841, wrote to President Tyler, stating that he had invented an apparatus by means of which he could destroy in a moment the most powerful man-of war, even though miles away, and asking that the Government give him opportunity for demonstrating the truth of his statement. The truth of his statement he demonstrated a year later by exploding a "torpedo" under water, in New York harbour, by means of electricity. Following up this success, he totally destroyed, by similar means, an old gunboat named "Boxer," and six weeks later, in sight of the President, General Scott, and others, he destroyed a schooner in the Potomac, distant five miles. Congress at once appropriated 17,000 dollars to continue his experiments and perfect his apparatus; and in two months from this time he blew up the big "Volta" in New York, in the presence of forty thousand spectators. All of these vessels were at anchor; but in the spring of 1843 Col. Colt demonstrated the further value of his invention by blowing up a vessel while under way in the Potomac, he being at Alexandria, five miles distant. These performances seemed in that day little short of magic, and their practical value was evident to many, yet they stopped short at this point, and were never resumed. Col. Colt endeavoured to get further assistance from the Government, but without success. From a variety of reasons, the authorities regarded his plans with disfavour, and Colt, disheartened and distressed, was compelled to abandon his invention just at the time when its success was assured but its details unperfected. But the Russians caught his ideas, and in the Crimean War we find the harbour of Sebastopol defended by torpedoes, many of which were operated by electricity. A few years later, in our Civil War, the electrical torpedo was extensively used by the Confederates in the protection of their harbours. In the Franco-Prussian

* Lecture delivered before the Franklin Institute, November 13, 1885, by Lieut. B. A. Fiske, U.S. Navy.

Digitized by Google

War torpedoes were so successfully employed in the defence of harbours that hostile ships did not even attempt to enter them; and in the Turco-Russian War, the mere suspicion that a harbour was defended by torpedoes was enough, in many instances, to keep a hostile fleet at a surprising distance—for the hostile fleet could not know just how far beyond a harbour the torpedo defence extended.

Since the experiments of Col. Colt the electrical torpedo has gradually improved, keeping pace with the progress of the sciences of electricity and engineering. Yet the original plan is the basis of the most elaborate and perfect instrument, and to the brain of Col. Colt we owe the surest defence we have for the cities and harbours of our extensive coast. At the present day an electrical torpedo consists of a strong, water-tight vessel of iron or steel, which contains a large amount of explosive, usually gun-cotton, and a device for detonating this explosive by electricity; and the most important form is that form which is anchored in a channel, and which is made to explode when an enemy's ship passes near it. These torpedoes are usually called "submarine mines." In our war most of these torpedoes were not operated by electricity, but by mechanical means, which consisted, for the most part, of levers protruding outside the case, and so connected with the explosive inside that when a lever was struck by a passing vessel a hammer inside was caused to fall upon a cap, just as when the trigger of a musket is pulled a hammer is caused to fall upon a cap. These mechanical torpedoes were used with considerable success by the Confederates, and they caused tremendous damage to the Union ships; but they had a number of defects, on account of which they have been almost entirely supplanted by the more complete, though much less simple, electrical torpedo. One of the defects of mechanical torpedoes was the danger attending the operation of planting them; another was the danger attending the operation of raising them; another was the fact that it was impossible to tell whether they remained in order, save by the expensive and suicidal plan of seeing if they would explode; and still another defect was that a mechanical mine did not know a friendly ship from a hostile one, but would sink either with absolute impartiality.

Now, it is clear that an electrical torpedo is free from all these defects, because it cannot be exploded unless a current of electricity be sent through it from a battery on shore or on board ship, so that the only thing to do when it is desired to make it harmless is simply to disconnect the battery; and when it is desired to put the mine into operation again the only thing to do is simply to reconnect the battery; moreover, the condition of the mine can at any time be determined by sending a very minute current through it, even though the torpedo be miles away, and buried in water many fathoms deep. In order to understand how electricity can explode a torpedo, it is sufficient to know that when a current of electricity goes through a wire it heats it to some extent, and if the wire be small enough the heat produced is sufficient to make the wire white hot. Clearly, if powder or fulminate of mercury be in contact with a white-hot wire, the powder or fulminate will be ignited, and if this powder or fulminate be enclosed in a tight vessel, together with powder or gun cotton, a tremendous explosion will ensue. Therefore, in order to explode a torpedo, the only thing necessary is to send a current of electricity through a very small wire, preferably of platinum, which is within the torpedo, and in contact with the explosive. The part of a torpedo which includes this small wire and its connections is called the fuse. In practice, the fuse is a separate thing, and is screwed into the torpedo case, the wire from the battery coming in through the fuse through a water-tight gland, so that, after the fuse has been screwed in, the torpedo, as a whole is water-tight, and may be left under water for months without injury. If the explosive charge is wet gun-cotton, as is now usually the case, the fuse contains fulminate of mercury, and is surrounded by a small charge of dry gun-cotton. The heat of the fuse-wire explodes the fulminate, the explosion of the fulminate causes the instant explosion of the dry gun-cotton, and this, in turn, causes the instant explosion of the whole charge of wet gun-cotton in the torpedo. But it is evidently not sufficient to be able to explode a torpedo; we must also know when to explode it, that is, we must know when the hostile ship is in such a position that she will be destroyed if the torpedo is exploded. Clearly, we can know this if we have a chart showing the exact position of each torpedo, and have also an arrangement by which we can know at any instant the bearing of a ship coming up the channel from two stations properly situated. If the ship comes into such a position that she is in the line of one of the torpedoes as seen from each station, she is clearly on the intersection of those lines, and is therefore directly over that torpedo, and the only thing necessary is to touch the electric key controlling that torpedo, thus sending an electric current through its fuse and causing its instant explosion. Another way is to have the telescopes at the two observing stations so fitted that when both point at any torpedo the current is automatically sent through that torpedo. Therefore, if the observer at each station keeps his telescope bearing on an advancing ship, electricity will do the rest, and the ship will sink when she comes within the radius of destructive effect of any one of the torpedoes

But what can be done at night, or in a dense fog? Evidently these systems will not answer then, because a ship cannot then be seen; and for this reason torpedoes now are frequently made absolutely automatic, so that whether the time be day or night, clear or foggy, the mere fact of a ship's striking a torpedo is sufficient to ensure her instant destruction. This result is secured by the use of what is known to electricians as an automatic circuit closer, that is, a device which, when subjected to certain conditions, automatically bridges over the distance between two points which were separated, thus allowing the current to pass between them. In submarine torpedoes it is usual to employ a small weight, which, when the torpedo is struck, is thrown by the force of the blow across two contact points, one of which points is in connection with the fuse, the other in connection with the battery, so that the current immediately runs over the bridge thus opened and through the fuse. In practice, these two contact points are connected by a wire, even when the torpedo is not in the state of being struck; but this wire is of such great resistance that the current is too weak to heat the wire in the fuse. Yet, when the weight above mentioned is thrown across the two contact points, the current runs across this bridge instead of through the resistance wire, and is then strong enough to heat the wire in the fuse and explode the torpedo. Now, the advantage of having a wire of high resistance between the contact points, instead of having no wire between them, is that the current which then passes through the fuse, though too weak to fire it, shows by its very existence to the men on shore that the circuit through the torpedo is all right. But instead of having the increased current, caused by striking the torpedo, to fire the torpedo directly, a better way is to have it simply make a signal on shore, and at the same time throw in a firing battery. Then, when friendly vessels are to pass, the firing battery can be disconnected, and when the friendly ship bumps the torpedo the working of the signal shows not only that the circuit through the fuse is all right, but also that the circuit-closer is all right, so that had the friendly ship been a hostile ship she would certainly have been destroyed. The action of a torpedo placed in the harbour and connected by a submarine cable to an electric battery or shore is thus shown to be quite a simple thing. But it should not be gathered from this that the protection of a harbour is a simple thing, or one that could be accomplished in a few days on the outbreak of war. It should be remembered that each torpedo contains from 100 to 1,000 pounds of gun-cotton, that hundreds of torpedoes will have to be used, that the amount of gun-cotton required will be enormous, and that it will be wanted in a hurry, but that the operation of making gun-cotton cannot be hurried. It must be remembered that to make the torpedo cases required will consume much time; that the making of the fuses is a matter requiring the greatest possible care and calculation; that the operation of properly laying down these heavy, and yet delicate, torpedoes, in deep water, even in the best possible weather, is an operation requiring great nautical and engineering skill and practice. Yet,

Digitized by Google

even after the best system of submarine mines has been laid down, it will be of no use unless an enemy's boats can be kept from counter-mining, and unless the operating rooms be furnished with the best instruments and thoroughly protected against capture by fortifications, guns, and ships. It is no uncommon thing to hear men of intelligence airily say, "Oh, in time of war we can defend our harbours by torpedoes." I do not think I am exaggerating when I say it would take a year to put the torpedo defences of our harbours into proper shape, even if Congress were to appropriate the money to-morrow. And after that a corps of men would have to be formed and thoroughly trained in laying down and taking up torpedoes and cables, making splices in submarine cables, testing circuits, managing electric batteries, &c.

In order to detect the presence of torpedoes in an enemy's harbour, an instrument has been invented by Captain M'Evoy, called the "torpedo detector," in which the action is somewhat similar to that of the induction balance, the iron of a torpedo case having the effect of increasing the number of lines of force embraced by one of two opposing coils, so that the current induced in it overpowers that induced in the other, and a distinct sound is heard in a telephone receiver in circuit with them. As yet this instrument has met with little practical success, but, its principle being correct, we can say with considerable confidence that the reason of its non-sucess probably is that the coils and current used are both too small.

Besides these stationary torpedoes or mines anchored in harbours, there is another class, called spar torpedoes, which are carried on spars protruding from ships or boats, and which consist for the most part of cases of steel holding about 30 pounds of gun-cotton, and fitted with electric fuses similar to those for exploding submarine mines. The torpedo on the end of the spar is connected by insulated wires with an electric battery in the boat or ship, and it is designed to be shoved under a hostile ship by a determined effort and exploded there. The current is sent through the fuse by pressing an electric key at the proper moment, or a simple automatic circuit-closer may be put inside the torpedo, so that when the torpedo strikes the ship a break in the circuit is automatically bridged over in the torpedo, thus allowing the current to heat the platinum wire in the fuse, and explode the torpedo.

Still another class of torpedoes are movable torpedoes. These contain not only explosive and means for exploding it, but also machinery for moving the whole through the water, and for steering it. A movable torpedo is, therefore, really a torpedo boat and torpedo combined. In one class of movable torpedoes, such as the Lay torpedo, the motive power is usually carbonic acid gas or compressed air, the steering and firing being done by electricity. One wire usually suffices, a simple step-by-step device accomplishing the operation of sending the current through different circuits in the boat, the current through one circuit causing the throttle of the engine to open, the current through another causing it to close, another putting the helm to starboard, another putting the helm to port, another firing the torpedo, &c. Therefore, the operator on shore or on board ship can, by moving his switch in the proper manner, cause the torpedo boat to go ahead, stop, turn to the right or left in such a way as to go directly toward the object of attack and then explode in contact with her bottom.

In another class of movable torpedoes the electric current not only steers the boat, but also propels it, there being an electric motor—or engine—inside, which, when supplied with the requisite current from an electric machine on shore or on shipboard, revolves rapidly, thereby causing the propeller of the boat to revolve in the same way that a steam engine causes the propeller of a steamboat to revolve. The current for steering may either be sent along a separate wire, which may be inside the other one, or a device may be used by which one wire will suffice for everything. Movable torpedoes being usually cigar-shaped, so that their section is circular, or nearly so, the electro-motor for an electric movable torpedo which will most nearly fit the space intended for it—in other words, the shape which permits the largest size for a given space—is clearly one in which the distance from the centre of the armature to the outside of the magnets is constant, so that the field-magnets form nearly a circle embracing the armature. The exterior form of the motor called the Griscom motor evidently seems to fulfil this condition well. The most successful movable electric torpedo thus far tried is the Sims torpedo, with which experiments have been conducted under General Abbot's superintendence for some time, and with very good results. Now, as all men-of-war and all forts are to be supplied with means for generating electricity on a large scale, it is clear that an electric movable torpedo can be easily adapted to naval and military requirements, the mechanism of the torpedo being exceedingly simple, and the only thing to be done to put it into operation being to connect it to a suitable electric machine, and introduce a keyboard, by which the direction and strength of the current can be controlled. The torpedo will then be ready to move at any instant, and will have a supply of power practically inexhaustible. Recent experiments in England have shown that the Whitehead torpedo—over which control ceases after it is fired—is not so formidable a weapon when fired at a ship under way as many supposed, for the simple reason that it can be dodged. Now, an electrical torpedo, over which control is exercised while it is in motion through the water, cannot be dodged, provided it be given sufficient speed. For effective work against ships capable of steaming fifteen knots per hour, the torpedo should have a speed of twenty knots. Now, there is no theoretical difficulty in the way of doing this, for a speed of 11 knots has already been recorded, though an electric torpedo, to get this speed, would have to be larger than a Whitehead having the same speed; and it may be conceived that a torpedo carrying, say, 50lbs. of gun-cotton, capable of going 20 knots per hour—so that it would pass over a distance of 500 yards in about 45 seconds, and yet be absolutely under control all the time, so that it can be constantly kept pointed at its target—would be a very unpleasant thing for an enemy to meet. Our civil war introduced another use of electricity into warfare, and gave birth to the art of military telegraphy. At first, the telegraph was used only in communicating along the regular telegraph routes, but eventually a corps of military telegraphers was formed, and instant communication became possible between detachments in the field. The advantage of the telegraph in conveying information and orders with despatch was found to be so great that foreign nations took the hint, and to-day a telegraph train is essential to all armies. No well-equipped force in the world is without means for rapidly connecting by the telegraph different head-quarters with each other, and with the different parts of an army; and in the Franco-Prussian war it was the telegraph, combined with the railroad, which made possible that wonderful speed and certainty of mobilisation and manœuvre that caused the swift destruction of the armies of France. In military telegraph trains, miles of wire are carried on reels in specially constructed waggons, which carry also batteries and instruments, some of the wire being insulated, so that it can rest on the ground, and thus be laid out with great speed, while other wire is bare, and is intended to be put on poles, trees, &c. For mountain service the wires and implements are carried by pack animals. Regularly trained men are employed, and they are drilled in quickly running lines, setting up temporary stations, &c. In the recent English operations in Egypt the advance guard always kept in telegraphic communication with head-quarters, and with England; and after the battle of Tel el-Kebir, news of the victory was telegraphed to the Queen, and her answer received in forty-five minutes. The telephone also has been used in military operations, and with great sucess; having an evident superiority over the telegraph for some purposes. One use of the telephone, in fact, is to assist the telegraph in cases where by reason of the haste with which a line has been run, the current leaks off, so that the receiving instrument will not work. The only thing necessary is to use a telephone to receive the message, and to use as a transmitter a simple buzzer, or automatic circuit breaker, controlled by an ordinary key. In many cases, where the ordinary receiving telegraph instrument refuses to work, the more delicate telephone thus used will work very satisfactorily. In endeavouring to use the telegraph and telephone for strictly naval purposes between ships, a number of obstacles have been met which have not

Digitized by Google

yet been overcome, though many ingenious devices have been attempted. It might seem at first sight as if, in the case of ships at anchor, telegraphic and telephonic communication among the ships and between the ships and shore would be an easy thing to establish. It is easy, and it has been established in the case of ships moored so that they cannot swing; but when a ship swings by a long chain, most of which is embedded in the mud, it becomes very difficult to devise an automatic means to keep the wire from being fouled and broken. In England, in the case of lightships, the difficulty has been surmounted, or rather avoided, by making the cable by which she rides hollow, and running an insulated wire along the long tube thus formed inside. This plan has been found thus far to work very well, even in the worst sort of weather. But the problem is much simplified when temporary communication only is desired between ships at anchor, between a ship and the shore, or between a ship and a boat which has been sent off on some special service, such as reconnoitering, sounding, &c. In this case portable telephones are used, in which the wire is so placed on a reel in circuit with the telephone that communication is preserved, even while the wire is running off the reel. The telephone has been used to some extent on shipboard for communicating between different parts of the same ship, giving orders to the magazines, battery, &c. The vibration of a ship is seldom so excessive as to impair the working of the microphone transmitter; and, in cases where it is excessive, the original magneto-transmitter has been found to work perfectly, getting rid entirely of trouble due to vibration, and at the cost of only a little of the loudness of tone as heard in the receiver. The telegraph and telephone are both coming largely into use in artillery experiments and drills, as in tracking a vessel as she comes up a channel, so that her exact position at each instant is known, in determining the spot of fall of a projectile, &c. In these cases two observers at the end of a base line electrically connected know at each instant the bearing of the vessel or the projectile from both ends of the base line, and the intersection of these lines of bearing is, of course, the position of the vessel or the projectile at that instant. In the case of a vessel this gives the range for the guns, and in the case of a projectile it shows by how much the projectile missed the target. In getting the time of flight, also, of projectiles, electricity is of value, since it enables the observers to get the exact time of start, a thing impossible to get with stop watches; but by making the projectile break a wire in circuit with a chronograph, the precise instant of start, to a thousandth of a second at least, is automatically registered. An application of electricity somewhat analogous to this has been in use for years in what are broadly called velocimeters, that is, instruments for ascertaining the velocity of projectiles. There are scores of patterns, but in all wires are cut by the projectile at different points of its flight, and the breaking of each wire causes the breaking of the electric current going through it, and this causes the appearance of marks on a surface moving along at a known speed. Now, knowing the rate at which this surface moves, and observing the distance on the surface between the marks cause by the breaking of the first wire and the marks caused by the breaking of the second wire, we can compute the interval of time which elapsed between breaking of the two wires; and now, knowing this interval of time, and knowing also the distance between the two wires, we can calculate at once the velocity of the projectile in going from one wire to the other.

Within the past few years electricity has come to be employed to a great and increasing extent in firing great guns, both on ships and in forts. In the case of ships the advantage of electrical firing lies in the fact that a gun can be fired more quickly by electricity than by other means. The ordinary means of firing are, as is well known, percussion and friction, and in each of these systems the moving parts have to be of such strength that considerable force must be exerted by the arm in order to operate them. Moreover, for prudential reasons, the line leading to them from the hand must be kept very slack, lest a lurch of the ship should cause such a movement of the man's body as to bring a strain on the line sufficient to cause the accidental firing of the gun. Therefore, when the gun captain finds the sights on the gun bear on the target he must then move his arm through a considerable distance, and exert considerable force, before the gun will be fired. It may seem as if the time were insignificant; but when it is considered how rapidly a ship rolls, and how swiftly a modern ship moves, and when it is remembered how small an error in elevation suffices to make a projectile fall short of, or go over, a ship which subtends a very small angle in a vertical plane, it will be seen that a fire which comes instantaneously with the coincidence of sights and target is better than one which does not. Now, in firing by electricity, the gun captain holds a sort of push-button in his hand, which he simply presses, when the sights bear on the target; and practical experiments abroad have shown that greater accuracy is attainable by this method than is attainable by the old methods. But not only are modern vessels of war fitted with means for electrically firing individual guns, they are also fitted with means for firing any desired number together, the whole broadside even; for the effect upon an enemy of a blow from a whole broadside at once, is very much greater than the effect of the same number of guns fired at different times. The simplest way of doing this is to lead the electrical wires from all the guns to an armoured fighting tower, where a cool officer, under the personal direction of the commander, with an electrical key board and a good system of sights, can deliver the whole fire of the broadside at once upon an enemy.

This officer being clear of the smoke and away from the excitement and bustle of the battery, and with a view of the whole horizon, can clearly handle the battery with its maximum effectiveness; and, moreover, as soon as the guns have been laid at the range and in the direction at which it is intended to fire them, the men can lie down and be protected in a measure from the murderous fire of machine guns. Suppose that two modern ships are about to engage in a naval duel on the high seas, and that they are advancing towards each other at a speed of 14 knots an hour each, so that they are coming together at a rate of about 46ft. per second. The ships will, of course, begin to play on each other with their machine guns as soon as they get within range, so that as soon as the great guns are ready, the men had best be made to lie down on the deck, in rear of their guns. Now, the battery of each ship will probably be composed of guns firing projectiles of from 100lb. to 1,000lb., and each commander, knowing how much damage can be done by one well-delivered shot, knowing how long it takes to reload a modern gun, and appreciating the great speed at which the ships are approaching, will probably reserve his fire until sure that he has a good chance of making every shot tell. He will hardly fire at 2,000 yards range, knowing that his chance of hitting the rapidly moving target is small, and knowing that it will be only about one minute before the enemy will be at 1,000 yards range. Now, at 1,000 yards range, the machine guns of both ships will be working vigorously, and each ship will have an excellent target, but a target improving so rapidly that a commander would not wish to throw away all the shot of his great guns until a closer range is reached. One gun, for instance, might be fired now, having been previously laid for this range, of course; but probably it would be best to reserve nearly the whole broadside to be delivered simultaneously as the ships rush by each other at pretty close range. With the heavy guns and carriages of the present day, it would be impracticable to keep a gun pointing at a ship under these circumstances, since both range and bearing are changing so rapidly. Therefore, the guns must be pointed in certain directions and laid for certain ranges, and fired when the enemy reaches the spots thus defined.

In the case of a fort the value of firing by electricity is evident, since it can be employed in connection with the instruments used for determining at each instant the position of an approaching vessel or army. Different guns being laid at different ranges and in different directions, an officer in the operating rooms can keep track of the exact position of the enemy, and when the enemy reaches one of the predetermined points, all he has to do is to touch an electric key and fire the gun or guns controlled by that key, knowing that those guns

Digitized by Google

are not only pointed in the proper direction, but also are elevated for the correct range. It would seem difficult to improve upon the accuracy obtainable by this method.

Whitehead torpedoes are now so arranged that they can be ejected by pressing an electric button; and the firing keyboard in the fighting tower of a ship indicates at any instant what guns and torpedoes are ready for firing. The fighting tower should also be fitted with engine and steering telegraphs, and indicators for showing whether the commander's orders to the engine and steering apparatus have been understood and executed, so that the commander can tell at a glance the exact state of affairs at battery, engine, and steering apparatus, and can have all the separate departments of his ship under absolute personal control.

Within the past three years the superiority of the incandescent electric light over all other lights for ship use has become more and more evident, and nearly all first-class merchant steamships launched, and all men-of-war, are fitted with electric lights. In men-of-war this light has even more advantages than in merchant ships by reason of its safety in illuminating magazines, shell rooms, torpedo store rooms, &c., and the ease and speed with which it can be used in signalling at night.

For some time the electric light was declared unsuitable for naval use, the reason being urged that if the wire carrying the current should be shot away in action, the whole ship would be plunged into darkness, and that the same thing would happen if any accident should befall the dynamo generating the current.

The answer to this very sensible criticism is that, first, different circuits must be arranged for different parts of the ship, so that an accident in any part of the ship will affect that part only; second, that the wires carrying the current must be arranged in duplicate, so that even in case one wire is shot away, the lights will burn as brightly as ever, since the other wire remains, and is of sufficient size to carry all the current; third, it is very easy to repair a break in a copper wire, even if it be shot away, the only thing necessary being to bridge over the break by a wire a few inches long, whose ends can be clamped, spliced, or even twisted on to the broken conductor on each side of the break.

(To be continued.)

PHYSICAL SOCIETY.—December 12th.

Prof. GUTHRIE, President, in the chair.

Mr. C. F. Casella and Prof. T. E. Thorpe were elected members of the Society.

The following papers were read: "On a Magneto-Electric Phenomenon," by Mr. G. H. Wyatt. The author had conducted a series of experiments with a view of testing experimentally an expression obtained by Mr. Boys for the throw of a copper disc suspended by a torsion fibre between the poles of an electromagnet, when the current was made or broken, and communicated by him to the Society on June 28, 1884. Discs of various metals and of various dimensions were used, the results being such as to agree with the theory within narrow limits. It was, however, found that when the throw of the disc was used to measure the magnetic field, the value obtained from the throw at break was uniformly greater than that obtained on making the current.—Prof. S. P. Thompson observed that the case presented was analagous to that of the ballistic galvanometer, and that for the theory it was necessary that the magnetic field should be made and destroyed before the disc had moved sensibly. Mr. Boys believed that the results of the experiments showed this to be the case, since the result of such a movement would be to increase the throw on breaking the current, when the disc made an angle of less than 45deg. with the lines of force, and to decrease it when the angle was between 45deg. and 90deg. whereas no such variation from the theoretical result was observed.

"On Some Thermodynamical Relations," by Prof. William Ramsay and Dr. Sydney Young. In this paper experimental proof is given of the following relations:—(1.) The amount of heat required to produce unit increase of volume in the passage from the liquid to the gaseous state, at the boiling point under normal pressure, is approximately constant for all bodies. (2.) If these amounts of heat be compared at different pressures, for any two bodies, then the ratio of the amount at the boiling point under a pressure p_1 to the amount at another pressure p_2 is approximately constant. (3.) The products of the absolute temperature into the rate of increase of pressure with rise of temperature are approximately the same for all stable substances. (4.) The rate of increase of this product with rise of pressure is nearly the same for all stable substances. (5.) A relation exists between the absolute temperature of all bodies, solid or liquid, stable or dissociable, which may be expressed in the case of any two bodies by the equation

$$\frac{T_a}{T_b} = \frac{T'_a}{T'_b} + C(T'_a - T_a),$$

T_a and T_b being the absolute temperatures of the two bodies corresponding to any vapour-pressure, T'_a and T'_b absolute temperatures at any other pressure, and c a constant, which may be zero, or a small positive or negative quantity. (6). The variations from constancy of the expression $t\frac{dp}{dt}$, though small, may be expressed by a similar equation. (7.) If L_a, L'_a, L_b, and L'_b, represent similar relations of latent heat at different pressures the same for a and b, it appears probable that

$$\frac{L_a}{L'_b} = \frac{L_b}{L'_b} + C(T'_a - T_a).$$

(8.) The ratio of the heats of vaporisation of any two bodies at the same pressure is approximately the same as that of their absolute temperatures at that pressure. The authors conjecture that this statement is also true of dissociating bodies. A large part of the experimental work consisted in obtaining the relation between vapour pressure and temperature of different substances, values of $\frac{dp}{dt}$ had been obtained from these observations in two ways, by plotting curves with t and p as co-ordinates and drawing tangents, and by the method of differences.—Prof. Perry suggested that the curve should be expressed in such a form as—

$$\text{Log. } p = d - \frac{\beta}{t} - \frac{\gamma}{t^2}$$

which Rankine has shown to be a very true expression for the relation between pressure and temperature, and that $\frac{dp}{dt}$ should be obtained from this by differentiation.—Prof. Guthrie hoped the authors would experiment upon the vapour-tensions of mixed liquids, a subject to which he had himself given some attention.

LIGHTHOUSE ILLUMINANTS.—ELECTRIC LIGHT APPARATUS.

REPORT OF PROF. W. GRYLLS ADAMS, F.R.S., &c.

(Concluded from page 117.)

2. If the rays after leaving the lighthouse lens are not absolutely parallel, but slightly divergent, so that they apparently come from a point farther off than the source, by a distance x,

Then $u = x + l$; and if u_1 be the distance of the source of light from the lighthouse lens, then u_1 and x are the distances of conjugate foci from this lens.

$$\text{Hence } L = \lambda \left(\frac{r-a}{d-r}\right)^2 \times \frac{c\,c_1}{f^2} \times \frac{(x+l-f)^2 u_1^2}{x^2} \times \frac{1}{a};$$

$$\text{but } \left(\frac{f_1 - u_1}{f_1}\right)^2 - \frac{u_1^2}{x^2} = \frac{f_1^2}{(x+f_1)^2}\left(\text{since } \frac{1}{u_1} - \frac{1}{x} = \frac{1}{f_1}\right).$$

Hence for a divergent beam,

$$L = \lambda \left(\frac{r-a}{d-r}\right)^2 \times \frac{c}{f^2} \times c_1 f_1^2 \left(\frac{x+l-f}{x+f_1}\right)^2 \times \frac{1}{a^l},$$

or

$$L = \lambda \left(\frac{r-a}{d-r}\right)^2 \times \frac{c}{f^2} \times c_1 f_1^2 \frac{\left(u_1 + \frac{f_1 - u_1}{f_1}(l-f)\right)}{f_1^2} \times \frac{1}{a^l},$$

$$= \lambda \left(\frac{r-a}{d-r}\right)^2 \times \frac{cc_1}{f^2}\left(u_1 + \frac{f_1 - u}{f_1}(l-f)\right)^2 \times \frac{1}{a^l}.$$

For a converging beam the value of

$$L = \lambda \left(\frac{r-a}{d-r}\right)^2 \times \frac{cc_1}{f^2}\left(u_1 - \frac{u - f_1}{f_1}(l-f)\right)^2 \times \frac{1}{a^l}.$$

These formulæ are very convenient for estimating the intensity of the source of light in the experimental towers when photometric observations are made by means of the achromatic lens in hut 2. For the Mew Island lens $f_1 = 920$ millimetres $= 36{\cdot}22$ inches;

$l = 6200$ft. $(f_1 - u_1) =$ the distance of the source of light from the principal focus of the lens.

$f = 7{\cdot}593$ft.
$c = 1{\cdot}414$ for the achromatic lens.
$c_1 = 1{\cdot}15$ for the lighthouse lens.

The value of a depends upon the transparency of the atmosphere.

To apply the formulæ for the intensity for different diverging and converging beams, when the photometric observations are made at hut 2. Supposing the arc strikes across at the edge of a 40mm. carbon—

$f_1 = 920$mm., or $3{\cdot}02$ft. nearly. $u_1 = 900$mm.

$$\frac{f_1 - u_1}{f_1} = \frac{2}{92} = \frac{1}{46} = {\cdot}02174$$

Digitized by Google

$$\left(u_1+\frac{f_1-u_1}{f_1}(l-f)\right)^2=\left(3+\frac{1}{46}\times 6200\right)^2=138^2=19,000 \text{ nearly.}$$

For the M.I. lens with the arc 2 inches or ·167ft. out of focus in focal plane—

$$\frac{f_1-u_1}{f_1}=\frac{\cdot 1666}{3\cdot 018}=\cdot 055347.$$

$$\left(u_1+\frac{f_1-u_1}{f_1}(l-f)\right)^2=(2\cdot 85+342\cdot 8)^2=119,400.$$

$$\frac{f_1-u_1}{f_1}(l-f)=342\cdot 8\text{ft.}$$

$$L=\lambda\left(\frac{r-a}{d-r}\right)^2\cdot\frac{cc_1}{f^2}\times\{119,400, \times\frac{1}{al} \text{ nearly.}$$

For the M.I. lens with the arc 4 inches out of focus—

$$\frac{f_1-u_1}{f_1}=\frac{\cdot 33}{3\cdot 018}=\cdot 11074, \text{ and } \frac{f_1-u_1}{f_1}(l-f)=685\cdot 3\text{ft.}$$

$$\therefore\left(u_1+\frac{f_1-u_1}{f_1}(l-f)\right)^2=(2\cdot 69+685\cdot 3^2)=473,340.$$

For the M.I. lens 6″ out of focus in focal plane—

$$\frac{f_1-u_1}{f_1}=\frac{\cdot 5}{3\cdot 018}=\cdot 1657, \text{ and } \frac{f_1-u_1}{f_1}(l-f)=1026\text{ft.}$$

$$\left(u_1+\frac{f_1-u}{f}(l-f)\right)^2=(1028\cdot 5)^2=1,057,000.$$

For the M.I. lens 8″ out of focus in focal plane—

$$\frac{f_1-u_1}{f_1}=\frac{\cdot 6}{3\cdot 018}=\cdot 2210, \frac{f_1-u_1}{f_1}(l-f)=1,368.$$

$$\left(u_1+\frac{f_1-u_1}{f_1}(l-f)\right)^2=(1370\cdot 3)^2=1,878,000.$$

Suppose $f_1-u_1=18\cdot 4$mm., or that the light comes from near the outer edge of a 40mm. carbon—

Then $\frac{f_1-u_1}{f_1}=\frac{1}{50}$.

$$l-f=l \text{ nearly,}$$

and $\left\{u_1+\frac{f_1-u_1}{f_1}(l-f)\right\}^2=\left(3+\frac{1}{50}\times 6200\right)^2=(3+124)^2=16,130.$

The value of the multiplying factors $\delta^2=\left(u+\frac{f-u}{f}l\right)^2$ for a diverging beam, and $\gamma^2=\left(u-\frac{u+f}{f}l\right)^2$ for a converging beam for a source of light placed at a distance $(f-u)$ from the principal focus of a lens of focal length f are given for every centimetre in the following table for a first order lens whose focal length is 92 centimetres. When the source of light is a point accurately in the focus of the lens, the multiplying factor = 10. For a distance of 1 mm. from the focus the value is about 100.

Values of $(f-u)$ in cm.	$\left(\frac{f-u}{f}\right)$	Divergence with M. I. Lens of 60°.	δ^2	γ^2

With carbons which are 30 mm. or 40 mm. in diameter the striking of the arc leaves ridges and hollows on the surface, which are gradually burnt away, without causing much actual variation, because the arc is scarcely ever accurately in the focus of the lens; thus, for a variation in the distance from 1 cm. to 2 cm. the illumination from the same source is only diminished fourfold, the rate of diminution from this cause increasing at a slower rate as the distance of the arc from the focus of the lens is increased.

If we inquire what is the angle of divergence corresponding to the position of the carbons 2 inches, or about 5 cm., out of focus, with 40 mm. carbons, we find that the angle of divergence varies from 4deg. to about 5½, and that the multiplying factor lies between 120,000 and 225,200; so that a light of 12,000 candles in the "A" tower would give an illumination of from ·1 to ·18 candle at the distance of hut 2, or from 4 to 7½ candles at the focus of the lens in hut 2.

Supposing that the carbons employed are 22 mm. in diameter, then, with an alternate-current machine, the arc may strike across from point to point of the carbons and may be accurately in the focus, or, more commonly, the arc will be formed from near the outer edge of the carbons at a distance of nearly 1 cm. from the focus. Under these circumstances, supposing the atmosphere were absolutely transparent and the light from the arc to be absolutely steady, the illumination at hut 2 might be expected to vary quite one hundredfold simply on account of the almost constant variations of the distance of the arc from the correct focus of the lens. Even supposing the section of the arc is 2 mm. in diameter, the multiplying factor for the light at hut 2 is

$$\left(3\cdot 02+\frac{1}{920}\cdot 6200\right)^2=100 \text{ nearly,}$$

whereas for carbons 2 cm. in diameter, with the arc at the outer edge, this factor is nearly 5,000. If there were no other cause of variation but this, we see that the illumination given at any one point, such as hut 2, through a lighthouse lens from the electric arc must be subject to very great variations of intensity.

Practical Application of the above Formulæ.

Now let us apply these theoretical results to the actual observations made at hut 2 when the arc in "A" tower was placed 2 inches, 4 inches, and 8 inches out of focus.

These experiments were begun on February 27th, and great care was taken on each evening to see either that the carbon was accurately in focus or that it was very accurately placed at the required distance from the focus of the lens. On February 27th the Mew Island lens was placed 8 inches out of focus. The cylindrical lens with vertical prisms was employed for comparison, and, taking the Mew Island lens in focus as giving 12 times the illumination, we get the illuminations of ·45 early in the evening, and ·75 candle at 11 p.m. At hut 2, if the arc be supposed to strike at the edge of the 40mm. carbon, this would correspond to 9,850 candles and 16,350 candles respectively, as the intensity of the source of light (the single arc) in "A" tower, making no allowance for the absorption of light by the atmosphere.

With the Mew Island lens 8 inches out of focus with the arc in the focal plane, the illumination at hut 2 was, in one case, ·004825 candle (185,500), in another ·005322 candle (204,600), and in another ·0039 candle (149,900), which correspond to illuminations of 12,240 candles, 13,500 candles, and 9,850 candles at the arc in "A" tower, as deduced from the above table. The mean of these results does not differ greatly from the mean of the results with the arc in the focus of the lens. The night was a clear one, as the Wigham 108-jet (single) gave an illumination of ·05884 candle at the focus of the lens in hut 2, *i.e.*, ·00143 on the hut (55,460), so that probably the coefficient of the atmospheric absorption was about ·9. Taking this value, the illumination given by the arc in "A" tower was about 13,180 candles.

Experiments were made on the evening of February 28th with the Mew Island lens 4 inches out of focus, and with the Mew Island lens in focus. Observations were also again made with the cylindrical lens with vertical prisms. At 8:30 p.m. the illumination with the vertical prisms was 1,573 candles at the focus, or ·0382 candle at hut 2 (1,483,000), which corresponds to ·4629 candle at hut 2 (17,790,000), with the Mew Island lens accurately in focus. This corresponds to an illumination of 10,100 candles in "A" tower. At 10:30 p.m. the haze had increased, and the observation with the vertical prisms gave an illumination of ·03137 candle at hut 2 (1,206,000). This corresponds to a source of light of 8,217 candles in "A" tower. From 10 to 10:30 p.m. an attempt was made to measure the illumination given by the Wigham gas 108-jet, and the six-wick oil, but the haze was too great to admit of any measurements being made. Hence there must have been a very considerable quantity of the light absorbed by the atmosphere.

The observations with the Mew Island lens, when the arc was 4 inches out of focus, gave an illumination of ·3753 candle at the focus of the lens in hut 2, or ·0092 candle at hut 2 without the achromatic lens (353,700). With the multiplying factor for the lens 4 inches, or 10cm. out of focus, this gives 4,844 candles as the illumination at "A" tower, and, allowing 1cm. more for one quarter of the breadth of the 40mm. carbon, this would give 5,860 candles as the illumination in "A" tower. A direct measurement with the Mew Island lens accurately in focus, when two machines were employed to give a single arc, gave an illumination of 16·58 candles with the lens at the focus in hut 2, *i.e.*, ·4066 at the distance of hut 2 (15,630,000), which corresponds to an illumination of 8,886 candles in "A" tower. Seeing that the haze was too great to admit of measurements being made with the 108-jet at hut 2, we should probably hardly be wrong in supposing that the illumination actually produced in the "A" tower was at least double the above values which have been derived from the observations in hut 2, making no allowance for the absorption of light by the atmosphere. This would give from about 10,000 to 12,000 candles for the light produced from one machine at an electro motive force of 48 volts and a current of 137 amperes, whilst two machines at an elecromotive force of 57 volts and a current of 180 amperes would give 17,770 candles

On March 6th and 7th measurements were made with the Mew Island lens with the arc accurately in focus, and also 2 inches out of focus.

On March 6th red and green glasses were used in measuring with the photometer, and on March 7th the same red and green glasses, and the blue solution of ammonia sulphate of copper which had been used in the photometric gallery were also used, and measurements were also made without these media. The measurements on March 6th, about 10:30 p.m., with the arc accurately in focus, gave 4,690 candles with red light, 10,600 candles with green light, and 8,236 candles with white light (1,210,000).

There was a considerable amount of haze, and the greater part of the evening was spent in various experiments in sky-flashing with the Wigham gas, and also with the electric light.

On March 7th the sky was remarkably clear; from hut 2 the French lights were brilliant, and even the Varne light could be clearly seen.

With the Mew Island lens and with the arc 2 inches out of focus but in the focal plane, at 9:15 p.m. the illumination was :—

·0635 candle at hut 2 by red light (2,441,000).
·1245 ,, ,, green ,, (4,785,000).
·2144 ,, ,, blue ,, (8,241,000).
·09654 ,, ,, white ,, (3,711,000).

These numbers correspond to—

8,150 candles by red light at "A" tower.
15,970 ,, green ,, ,,
27,520 ,, blue ,, ,,
12,390 ,, white ,, ,,

At 10 p.m observations with cylindrical lens and vertical prisms and arc in focus gave—

82,790 candles by red light at "A" tower.
13,730 ,, green ,, ,,
16,630 ,, blue ,, ,,
10,390 ,, white ,, ,,

At 10:15 p.m. observations with the Mew Island lens accurately set with the arc in the focus gave—

·4690 candle at hut 2, or 8,925 candles at "A" tower by red light (18,030,000).
·7044 candle at hut 2, or 15,380 candles at "A" tower by green light (27,080,000).
·6898 candle at hut 2, or 15,060 candles at "A" tower by blue light (26,530,000).
·5996 candle at hut 2, or 13,090 candles at "A" tower by white light (23,040,000).

The values given in the same way with two machines to one arc were:—

·3893 ... 8,500 ... red light (14,960,000).
·8636 ... 18,860 ... green ,, (33,200,000).
1·525 ... 33,300 ... blue ,, (58,610,000).
·9280 ... 20,260 ... white ,, (35,670,000),

no allowance being made for absorption by the atmosphere.

On the evening of April 9th some observations were made at hut 2 to determine the relative illuminating powers from a single arc when supplied from one machine, from two machines clutched together in series, and from two machines running together parallel for quantity.

The cylindrical lens with vertical prisms was used, and the illumination at hut 2 was ·0263 candle with one machine (1,011,000), which corresponds to 6,890 candles at "A" tower.

The illumination at hut 2 with two machines in series was ·0395 candle (1,518,000), corresponding to 10,360 candles at "A" tower, and with two machines parallel for quantity was ·0406 candle at hut 2 (1,561,000), or 10,640 candles at "A" tower, no allowance being made for absorption by the atmosphere.

The evening was fairly clear. At first the Calais light was not seen, but during the evening there was a slight improvement, and at the end the Calais light was just seen. The order of the observations and the current and electromotive force are given in the above table :—

At 9:30 p.m. the change was made in the connections between the two machines, but from the observations of E.M F. and current it would appear that probably the machines were not clutched together, and therefore they would alter their phase and so fall into step together; and so as regards the external circuit would still be working as two machines parallel.

In this table the intensity of the source of light is deduced from the illumination measured at hut 2, by means of the formulæ on pages 117 and 135, in which no allowance is made for the absorption by the atmosphere.

The values (given for comparison) of the single 108-jet or 108′ will show the change in the transparency of the atmosphere during the evening

Effect of Placing the Electric Arc out of the True Focus of the Lens.

On February 27th, when the arc was 8in. out of focus, observations were made as to the effect of raising the arc 1in. and 2in. above the focal plane, and of lowering it 1in. and 2in. below the focal plane.

In the first case the light was thrown down and illuminated the space extending from near the lighthouse quite to the horizon.

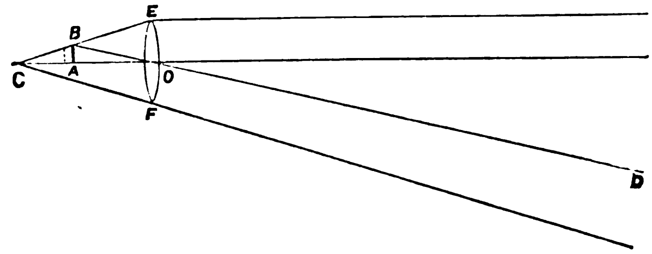

Fig. 6.

Let E O F represent the refracting portion of the lens.

Suppose it to subtend an angle of 30 deg. at C the principal focus. Let C O = 36in. Let C A = 8in., and A B = 2in. When the arc is at B, which will then be very nearly on the line C E, the rays proceeding from B to E will be refracted to the horizon. The axis of the beam will be in the direction B O D, inclined at an angle about 4 deg. below the horizon. At the distance of one mile from the lighthouse, the axis of the beam would be 380ft. below the focal plane.

The portion of the beam falling on the part of the lens near F will be refracted in a direction inclined at an angle of about 8 deg. below the horizon, and at the distance of half a mile will reach a point at a depth of 380ft. below the focal plane, *i.e.*, at the South Foreland the central refracted portion of the beam would illuminate the sea up to within half a mile of the lighthouse.

The intensity of the light in the direction of the axis of this beam, from a point 8in. out or focus, is about $\frac{1}{150}$th part of the intensity when the arc is placed accurately in the focus of the Mew Island lens, *i.e.*, not very far short of the intensity from the quadriform 108-jet gas, being about $3\frac{1}{2}$ times the intensity from the single 108 gas jet as mentioned on the same evening, when it gave an illumination of ·001443 candle at hut 2 (55,470)

The divergence from the refracting portion of the lens is about 8 deg., and the beam extends from the horizon, and will illuminate the sea up to within half a mile of the lighthouse.

The whole divergence of the reflected portion of the beam would be about 20 deg., and both on account of this great divergence, as well as on account of the diminution in the intensity of the beam, it is quite clear that it would never be advisable in practice to put the source of light so far as 8in. out of focus.

Let us consider the case when the arc at B is 4in. out of the focus of the lens, and raised 1in. above the focal plane.

C O = 36in., C A = 4in., A B = 1in. and O E about 10in

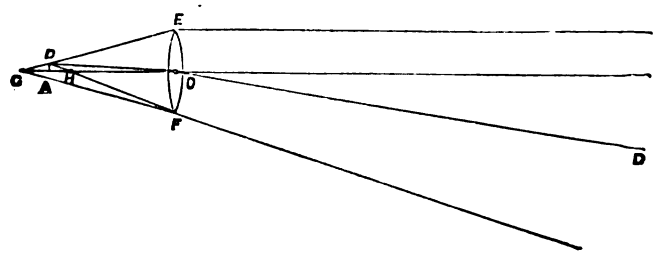

Fig. 7.

Under these circumstances the point B will be very nearly on the line C E, and the light proceeding from the arc at B to the portion of the lens near E, will be refracted to the horizon, whilst the axis of the beam will be inclined at an angle of about 2 deg. below the horizon, and at a distance of 2 miles from the lighthouse would be at a depth of 330ft. below the focal plane.

The divergence of the refracted portion of the beam will be about 4 deg. and the portion of the beam refracted near F will be 330ft. below the focal plane at a distance of 1 mile from the lighthouse.

Digitized by Google

This arrangement will illuminate the surface of the sea from the horizon up to within 1 mile of the lighthouse, and the intensity of the light in the direction of the axis of the beam, striking the sea at a distance of 2 miles, will be about $\frac{1}{15}$th part of the full intensity of the electric beam through the Mew Island lens with the arc accurately in the focus, and will be about double the intensity of the quadriform 108-jet gas.

The whole divergence of the reflected portion of the beam would be about 10deg., and a portion of the light would be thrown down on the sea up to within half a mile of the lighthouse at the South Foreland.

Probably this divergence would be regarded as giving a longer period than necessary for the period of visibility of the beam when it is revolving, and it would not be advisable to diminish the intensity of the beam so much by putting the arc so much as 4 inches out of the focus of the lens.

Let us consider now the experiments of March 6th and 7th, when the arc was 2 inches out of focus in the focal plane, and also raised ½ inch above and lowered ½ below the focal plane.

When the arc is 2 inches out of focus and raised ½ inch above the focal plane, the upper part of the beam, as in the last case, will be refracted parallel to the horizontal plane, and will reach to the horizon (*see* Fig. 7), but the divergence will be only about 2deg. instead of 4deg.; hence, while the axis of the beam will be 330ft. below the focal plane at a distance of 4 miles from the lighthouse, the part of the beam refracted near F will be 330ft. below the focal plane at a distance of 2 miles from the lighthouse.

The intensity of the light in the direction of the axis of the beam, striking the sea at a distance of 4 miles, will be about $\frac{1}{13}$th of the full intensity of the electric beam through the Mew Island lens with the arc accurately in focus, *i.e.*, thus, at the South Foreland the Mew Island lens, with the arc 2 inches within its focus and raised half an inch, will give a beam whose axis strikes the sea at a distance of about 4 miles from the lighthouse, and whose intensity is equal to the full intensity of the electric arc when placed accurately in the focus of the cylindrical lens with vertical prisms.

This intensity is from six to seven times the full intensity of the *quadriform* 108-jet gas.

The full intensity of the electric beam through the Mew Island lens with the arc accurately in its focus being from 70 to 80 times the full intensity of the quadriform 108-jet gas through the same lens

The whole divergence of the reflected portion of the beam from the outer prisms would be about 5½deg., and a portion of the light would be thrown down upon the sea at the South Foreland up to within 1 mile of the lighthouse, the lower edge of the beam at the distance of 1 mile being at a depth of 350ft. below the focal plane. This arrangement of the Mew Island lens when revolving would give a duration of flash nearly equal to that from the "C" tower, where the six-wick oil light has a divergence of about 6½deg., and would illuminate the sea from a point 1 mile from the lighthouse up to the horizon, the strongest part of the beam meeting the sea level at a distance of about 4 miles from the lighthouse. The measurements of candle-power at hut 2, when the arc was above or below the focal plane, show that in the focal plane the intensity was about from two-thirds to three-fourths of the intensity at the same distance along the axis of the beam. Hence the illumination thrown on the sea increases on approaching the lighthouse, and at 2 miles is from two to three times the illumination thrown on the sea at the distance of 4 miles.

With a light so brilliant as the electric light it would seem advisable to make the diameter of the lantern 4 inches smaller, to place the arc in the centre, and to raise it about half an inch above the focal plane. This will produce a beam of about 5½deg divergence with the Mew Island lens, and will illuminate the sea from the horizon to within 1 mile of the lighthouse.

In this way the concentration and the want of steadiness of the electric light would be greatly remedied, so that in hazy weather it would be better seen by the mariner, and when revolving would no longer resemble a sudden brilliant flash, but rather a steady and intense light lasting long enough to give him his bearings. I would recommend this method of using the electric light in lighthouses, and believe that if it were so used it would be hailed with delight by the mariner.

If we apply the above formulæ to find the illumination from one 20-candle light placed in the focal plane in the axis of the lens, at distances of 1 cm., 3 cm., 5 cm., 7 cm., 9 cm., 11 c.m., and 13 cm. respectively, from the focus of the lens, the illumination at hut 2 with the Mew Island lens would amount to ·0001754, ·00002067, ·00000754, ·00000386, ·00000234, ·00000157, ·00000113 candle repectively.

Now, taking one in front of and another behind the focus at each distance, the whole illumination amounts to ·000425 candles, *i.e.*, about one-third of the actual illumination gained from the single 108-jet in actual experiments.

If we attempt to estimate what light reaches hut 2 or any one distant point from the Wigham gas burner, we must take only those burners which are near enough to the axis of the lens to be focussed near to the position of the disc in hut 2.

Hence there can hardly be more than one burner in front and one behind the focus in each ring which can illuminate the point. Also, of these, a considerable fraction of the light from the flames behind will be absorbed by those in front.

With 14 lights, one behind the other in a row, in the seven rings of the 108 gas jet, it would appear from the investigations on the transparency of flames that a very small proportion of the light from any except the five or six front lights will be allowed to pass through.

Another mode of Comparison of Sources of Light.

Another way of estimating what light the 108-jet will give at any distance would be to assume that from the large area of flame the light is uniformly distributed over a given area, and to measure the divergence of the beam.

Taking the horizontal divergence at 14¼deg., as measured by me on September 22, 1884, we get the light diverging from the source and falling upon the lens, which subtends 60deg. at the focus, concentrated into a conical beam with an angle of 14¼deg. at the vertex of the cone.

Hence, at a distance x from the source, the illumination will be

$$\frac{L}{x^2} \times \left(\frac{\tan 30^\circ}{\tan 7\frac{1}{8}^\circ}\right)^2.$$

Hence, at the distance of hut 2 the illumination would be ·0012 candles from a source of 2,160 candles behind the Mew Island lens.

Probably the illumination is not quite equally distributed over a given area, but would be somewhat brighter in the axis of the beam, so that at the distance of hut 2 in a clear atmosphere the illumination would be greater than the value here indicated.

On April 1st the quadriform 108-jet gas was measured by me in hut 2 without the achromatic lens, and gave an illumination of ·004995 candles (192,000), and the single 108-jet was measured by means of the lens in hut 2, and gave an illumination of ·001216 candles at the distance of hut 2 (46,740).

Observations with the triform six-wick oil light on the same evening (April 1st) gave the illumination from the six-wick triform oil as ·798 of the quadriform gas.

Hence the six-wick triform gave an illumination of ·003987, or very nearly ·004 candles (153,300).

The measurement of the Douglass 10-ring gas on the same evening, without using the achromatic lens, gave an illumination at hut 2 of ·00186 candles (71,500), *i.e.*, more than half as much again as the illumination from the 108-gas jet.

This method of estimating the intensity of illumination at any point is not applicable to the electric light, since the light from the arc or from any source of light of small diameter is not uniformly distributed over the illuminated area.

Experiment with Incandescent Lamps.

A Swan incandescent lamp of 100 candle-power, and also a 50-candle lamp of smaller size, were, each in turn, placed in the "A" tower in the focus of a Mew Island lens. The beam was turned on hut 2, and the measurements made of the illumination were compared with the illumination from the 108-jet gas in the "B" tower. The following results were obtained:—

Source of Light.	Illumination at Hut 2.	Naked light giving the same Illumination.
108-jet gas	·001423	54,700
100-candle glow lamp	·00084	32,300
50-candle glow lamp	·00099	38,000

The glowing fibre of the compact 50-candle lamp gave a stronger illumination than the larger 100-candle lamp, and more than two-thirds of the illumination from the 108-jet gas light behind the same lens.

This experiment suggests the interesting question whether the grouping of glow lamps within the compass of a sphere six inches in diameter will not give a very effective lighthouse light.

Sky Flashing with the Electric Light.

On the evening of March 6th, from 10:15 p.m., and again on the evening of March 7th, from 8:30 p.m. to 9:10 p.m., experiments were made with the Mew Island lens revolving in front of the electric arc, which was placed below the focal plane so as to throw the electric beam above the horizon, to illuminate the haze and floating clouds.

With the electric arc 2 inches and 3 inches below the focal plane, a brilliant cone of light passed over the heads of the observers at hut 2, which was apparently almost divided into two separate cones with their vertices opposite ways, the space within an angle of about 30deg. over the head of the observer being so transparent as to send very little light to the eye. In the distance, towards Ramsgate, the cone of light seemed to gather again and to dip towards the horizon, an effect due to the fact that the observer was looking nearly in the direction of the beam. On March 7th the light was thrown so as to describe a wider cone, by lowering the electric arc 6 inches below the focal plane. By this means the haze and clouds at a greater elevation were brilliantly illuminated.

The arc was also placed 2in. out of focus so as to give a divergent beam, and lowered 6in. below the focal plane, while the Mew Island lens was revolved in front of it. In this way a brilliant but very divergent beam was thrown into the atmosphere above the heads of the observers, showing to perfection any effect which may be produced by flashing lights on the sky. It is possible that it may be advantageous to the sailor on a fairly clear night to have the electric light illuminating the sky over his head instead of falling on his vessel, especially if he should be approaching the light. The diverging cone of the electric light when thrown upon the sky may be seen above their horizon by vessels far beyond the horizon of the lighthouse. If the arc be placed 3in. below the focal plane, the focal length of the lens being about 3ft., we see that at a distance of about 12 miles, the beam would be about 1 mile above the observer.

There does not seem to be any special advantage to be obtained by throwing the light up into the sky during a fog, for experiments on the penetration of a fog by light have shown that on approaching the electric light in a fog the observer first becomes conscious of the presence of a distinct source of light by observing a bright point, the electric arc itself, or, when a lens is used, the image of the electric arc formed by the lens.

Digitized by Google

When the source of light is alternately eclipsed and exposed, then the observer becomes conscious of the existence of the source of light; but for a very considerable density of fog in which he is enveloped he cannot fix upon the direction of the source, the light coming to his eye being almost equally bright in all directions.

Experiments with Steam Fogs.

In experiments with steam in the photometric gallery the electric light and the 108-jet gas were tried, and were completely shut out by 30 or 40 feet of fog. As the fog cleared, and as both lights were alternately eclipsed and exposed, the observer, being near the outer limits of the fog, first became conscious of the light from the electric arc, and recognised it by its whiteness, after which a considerable interval elapsed before he recognised the yellow glare of the gaslight. Then, as the steam gradually cleared away, in the midst of the white electric glare, he caught the brilliant point of light of the electric arc, and after that he had to wait a considerable time longer before he was able to see any portion of the source of the 108-jet gaslight.

When first the faintest illumination from the electric light became visible, the illumination was not red or yellow, but white, and at any and all distances there could be no question whatever as to the source which was giving the light. The illumination of the fog was of the same colour as the source of light, showing that with a mixture of air and steam, forming a cloud, rays of different colours were absorbed and scattered very nearly in the same proportions. This shows that the proportion of the electric light which is scattered by such a fog is no greater than the proportion from any other source of light, and that we may make use of the same coefficient of transparency for the different lights.

A Wigham 108-jet gas burner, giving an illumination of about 2,500 candles, and a De Meritens arc lamp, giving about 12,000 candles, were placed at one end of the gallery. When the daylight was shut out and the fog admitted, I could see no light at all at any distance beyond 100ft. From 90ft. to 100ft., when the electric light was exposed, there was just the faintest possible illumination of the fog, but when the gas was exposed and the electric light eclipsed not the slightest illumination could be seen, until a point 65ft. from the source of light was reached. On approaching nearer, at 50ft., the glowing 44mm. carbons became visible, and at 36ft. the whole breath of the gas flames came into view at once.

The electric light of 12,000 candles, the Wigham 108-jet gas of 2,500 candles, a single burner of 20 candles, and the Douglass one-candle standard were observed in the same steam fog with the following results:—

The glowing carbons were seen to a distance of 117ft., the 108-jet gas was seen to a distance of 80ft., the single gas jet was seen to a distance of 70ft., and the standard candle was seen to a distance of 55ft.

These results show that the distance to which a light is seen in fog depends on the intrinsic brightness of the flame, and that an increase in the size adds very little to the penetrative power.

LAUNCH OF A TELEGRAPH CABLE STEAMER.

Messrs. R. Napier and Sons launched, on Monday last, from their shipbuilding yard at Govan a twin-screw cable steamer for the Eastern Telegraph Company, London, specially designed by Mr. Joseph Birnie for laying and repairing the company's submarine cables. The vessel is built of steel to class 100A at Lloyds's, and is of the following dimensions:—Length, 250ft.; breadth, 34ft.; depth, 25·4ft.; with a gross tonnage of about 1,500 tons. Externally the steamer with her cutwater stem has a very handsome appearance, while internally the arrangements are of the most complete character to suit the peculiar service for which she is intended. Besides having the usual appliances of a first-class merchant steamer, the vessel is fitted with special tanks for holding cables, and has been subdivided into 27 water-tight compartments for trimming and ballasting purposes. The cable gear is of the most modern design, and is driven by a pair of powerful engines. It consists of bow guards and triple sheaves, with leads for paying out and taking in cables, dynamo meters for registering the pressure, steam sounding machines, &c. The bow sheaves over which the cables are passed give the vessel a peculiar appearance, but they have been wrought in by the builders in an ingenious manner to form part of a clipper bow, which adds to the symmetry of the steamer. Very complete accommodation has been provided for the officers and electricians, and as the vessel is intended for service in hot climates Messrs. M'Whirter and Roberts' steam ventilating apparatus has been fitted throughout the ship, which will also be lit by a very complete system of electric light. Two sets of compound surface condensing engines have been constructed at the builders' Lancefield Works, under the supervision of Mr. A. Beldane, the company's superintending engineer.

After the launch the company adjourned to the model room, where lunch was served. Amongst those present were:—Messrs. A. C. Kirk, John Hamilton, and James Hamilton, of the builder's firm; Sir James Anderson and Mr. John D. Pender, directors of the Eastern Telegraph Company; Sir William Thomson and Lady Thomson, Mr. Joseph Birnie, who designed the ship; Mr. Renwick, the company's representative in Glasgow, and Mrs. Renwick; Principal Jamieson, Mr. M'Whirter, London; Mr. George Agnew, Superintendent Hamilton, &c. Mr. A. C. Kirk, who presided, gave the toast of "The 'Mirror' and the Eastern Telegraph Company." He remarked that, although the "Mirror" was a reflection of all the perfections of telegraph ships, she had not been called the "Mirror" for that reason. Her name was called "Mirror" in honour of Sir William Thomson's great scientific discovery. Sir James Anderson, with whose name the toast was coupled, replied. He passed a eulogium on Sir William Thomson for the skill he had displayed in the science appertaining to electricity. They were now able to telegraph to Egypt in ten minutes, to America in four minutes, and he did not think this could be beat. They had also telegraphed to India, and received a reply in five minutes. The "Mirror," he said in conclusion, had been in all her arrangements entrusted to Mr. Kirk, and he had no doubt she would reflect the great skill of that gentleman and the ability of her builders, one of the greatest firms in the country, and would also do credit to Sir Wm. Thomson's gaeat invention. Sir Wm. Thomson, after acknowledging the kind words spoken of him, proposed in complimentary terms "The Builders." Mr. James Hamilton replied, remarking that it was the fourth telegraph vessel built by them, and they now knew the requirements of the telegraph companies, and were quite prepared to equip telegraph ships from keel to truck. Sir James Anderson proposed the "Health of the Chairman of the Telegraph Company, Mr. Pender." Mr. E. D. Pender, in his father's absence, acknowledged the toost, and in graceful terms proposed the "Health" of the lady who named the vessel, Lady Thomson. Sir William Thomson responded, and the proceedings shortly afterwards terminated.

COMPANIES' MEETINGS.

Mediterranean Extension Telegraph Company (Limited).

A general meeting of the shareholders of this Company was held at the Cannon-street Hotel, on the 21st inst., for the purpose of receiving an account from the liquidators showing the manner in which the liquidation proceedings have been conducted and the property of the Company disposed of; and for fixing the liquidators' remuneration.

The Hon. Ashley Ponsonby (the joint liquidator with Mr. John G. Griffiths) presided, and having read the notice convening the meeting, said: You have all, I suppose, had a copy of the accounts placed in your hands, and we shall be very happy to give you any explanation you may wish on those accounts. You will observe that there is an item of £330. 0s. 3d. unclaimed dividends. That in the ordinary course of events would be an asset, but under existing circumstances we shall have to ask the intention of the Court as to what we may do with it. Every effort has been made to find out those to whom it belongs, but up to the present moment we have been unable to get any information whatever. Therefore, as to that £330, we shall have to ask the intention of the Court. You find that we have a balance to deal with of £1,739. 15s. 9d. Out of that amount it is proposed to return you another 1s. 2d. per share. That will absorb £886. 13s. 4d., and it is proposed to give that balance to the liquidators. It has always been the wish that some remuneration should be given to the old officers of the Company. Unfortunately, as you are aware, poor Mr. Tombs died shortly after the liquidation began, and he has therefore ceased to be a claimant in any way; but there are two other officers to whom, I think, the remarks of Sir James Carmichael apply. At one of the meetings Sir James, in reply to a shareholder, stated that if the officials, Mr. de Normann, Mr. Tombs, and Mr. Atmore were thrown out of employment, they ought to be remunerated. Well, we have taken counsel's opinion on the question, and we find we are unable to do that in the ordinary way; but you have the power of conferring on the liquidators' a sum for their remuneration, and out of it, if you pass the resolution that will be proposed, we intend to give Mr. de Normann £250, and Mr. Atmore £100, making together £350. That is the suggestion which we are going to make; and I feel the less hesitation in doing it, as you may all be aware of the long service which Mr. de Normann gave to the Company since its commencement, and from the fact that he is in old age and failing health. With reference to Mr. Atmore, he has given us great assistance, and I feel that £100 is the minimum that we can offer him. That will absorb the whole of our assets, with the liquidators' remuneration. We have now been over two years in liquidation, and we feel that we are not asking too much. It may be asked of us, Why have you been two years, as that seems a long time? In the first instance, almost immediately after the resolution to wind up this Company was arrived at the Italian Government gave us notice that we had no powers to sell the concessions, but that they would assist us in doing so. From that time forward till a whole year had passed negotiations were going on in Italy, and the Italian Government introduced a Bill into their Houses of Parliament, which was passed, authorising us to make over the cables and concession to the Eastern Company. That took rather more than a year. We next received notice of the action that was about to be commenced—of which I wish to say a few words—between the preference and the ordinary shareholders. That action was commenced, and the last part we had to do with it was in regard to the taxed costs, which were not delivered till last August. You may suppose that, although we had nothing directly to do with that action, we had a considerable amount of work in connection with it, as they were sending for our books, and looking into our accounts, and wishing for information. All this gave us no little anxiety, although we ourselves were no parties in any way to the action, which, as you are aware, was decided by the Courts in favour of the ordinary shareholders. All that your liquidators had to do was to pay the bills, which were very excessive, and we were very sorry we had to pay them. That was not done till last August; and we had to give you a whole month's notice in the *Gazette*. We are now met to-day to give you a statement of accounts. This is, I think, as clearly as I can state, the whole work of the liquidators. Is there any other point you would like me to go into? Mr. Griffiths will answer you on any point connected with the figures. I would only add that, although there has been this delay, you were not

Digitized by Google

kept out of your money, and we have paid you up to the present time £3. 5s. a share, and now we propose, as I have said, to give you another 1s. 2d.

Mr. WELLS said he thought, after the speech of the Chairman, that the shareholders ought to be very much obliged to the gentlemen who had acted as liquidators. For his own part he was very agreeably surprised at the amount already returned, and he was very pleased that there was a chance of their getting an additional 1s. 2d. a share. He had much pleasure in proposing the following resolution :—"Resolved, that the audited accounts, showing the manner in which the liquidation proceedings have been conducted and the property of the Company disposed of, be and are hereby adopted and approved."

Mr. CLOUT seconded the motion, which was carried unanimously.

Mr. NORRIS then moved the following resolution :—"Resolved, that it be recommended to the liquidators to declare a final dividend of 1s. 2d. per share on the preference and ordinary shares of the Company."

Mr. WHITTAKER seconded the resolution, which was also carried unanimously.

Mr. THOMAS ADAMS said that as the officials had been deprived of what they had a reasonable right to expect—a long continuance of their services—he thought the proposal to give them some compensation was only a right one. He also thought that the liquidators should be remunerated for what they had done in winding up the concern in such a very short time compared with some other cases. He concluded by moving the following resolution :—"Resolved, that the remuneration to the Hon. Ashley G. S. Ponsonby and J. G. Griffiths, Esq., the liquidators of the Company, be fixed at the sum of £853. 2s. 5d., the liquidators undertaking to pay and satisfy any outstanding claims on the part of the late officials of the Company." He did not know whether the claims of the officials were considered legal ; but the shareholders took it that the liquidators regarded them as moral claims.

Mr. GRIFFITHS : It is not a claim that we could at once admit as legal; but a legal claim might be made, and that might keep the liquidation open for a long time.

Mr. LEAN seconded the motion, which was carried unanimously.

The CHAIRMAN having intimated that that closed the business,

Mr. GRIFFITHS stated that there would be one more meeting, so as finally to wind up the Company, but there would be nothing to do. It would not be held till the liquidators got the direction of the Court as to the unclaimed dividends.

A SHAREHOLDER : Will you pay the 1s. 2d. a share before then ?

Mr. GRIFFITHS : We shall pay that now, directly, but we shall have to come before the shareholders with our final accounts when we get the direction of the Court as to the unclaimed dividends of £330.

A SHAREHOLDER inquired whether they could not pass a resolution to the effect that unless that amount were claimed within a certain period it would be divided among the shareholders who had come forward ?

The SOLICITOR (Mr. Campbell) said he feared that when once the money got into the Court of Chancery it would be a long time before they let it out again, unless the shareholders showed they had a right to it.

Mr. WELLS said that they had a right to it under the Articles of Association.

The SOLICITOR : Yes, but the Company is in liquidation. If it was not for the holding of these funds by the Government and others we should not hear of the large windfalls we do.

The CHAIRMAN : I am afraid this will not be a large windfall ; but still it would be 6d. a share.

The SOLICITOR : No doubt Mr. Wells is correct that we have a right to this by the clause (which he read) in the Articles of Association. As a going concern we could say to the Court that we had a right to divide this amount if the parties do not come forward and claim their dividends within three years.

Mr. WELLS : You will do the best you can for us in the matter ?

The SOLICITOR : Yes, certainly. I think if it is not claimed within three years it ought to be divided among those who do come forward.

Mr. WELLS proposed a vote of thanks to the Liquidators, who, he thought, had put down a very small amount for their remuneration. He thought the result of the liquidation must be considered very gratifying.

The SOLICITOR also thought it was very satisfactory, remembering that when the liquidation commenced the opinion of the public was that the value of the shares was about £2, whereas £3. 6s. would be returned.

A SHAREHOLDER having seconded the motion, it was carried unanimously.

The CHAIRMAN returned thanks, and the meeting then separated.

LEGAL.

Electric Lighting at Witney.

In the Queen's Bench Division of the High Court of Justice, on Monday, before Mr. Justice Field, judgment was given in the action of the Provincial Brush and Electric Light and Power Company *v.* Shillingford and Bateman, which was tried a fortnight before. The learned Judge said this was a claim for £53. 17s. 2d., the balance of an account for an installation of the electric light at the defendants' brewery at Witney, in Oxfordshire. The defence was that the installation was "not a success." The original claim was for £153, and the defendants, having paid £100, claimed to have that amount returned, as having been paid by mistake. The Judge explained how the electric light was produced. The motive power in this instance was furnished by a 3½ horse-power steam engine belonging to the defendants, with which the plaintiffs had nothing to do. That engine actuated the dynamo, which deposited its electric force into the commutator, which took it in the shape of a current and carried it first to the accumulator, where it was stored to be available when the engine was not at work, and thence it passed to the lamps. The contract was somewhat uncertain with regard to the number of lamps ; it was intended originally to be 15, whereas 20 or 21 were actually placed, the plaintiffs remarking that if the larger number of lights was provided they must not be all run at the same time. The estimate was dated July 15th. The defendants asked for a guarantee that the installation should be a success, and the plaintiffs expressed their willingness to give such a guarantee if the installation was carried out under their personal superintendence. Accordingly, written instructions were given to the defendants' engine driver as to how to work the engine with a view to the adequacy of light ; and it might be a question whether, for such delicate operations, a man was not required who was of a superior education to an ordinary engine driver. This man was instructed how to work the engine, and was told it must be so worked that the electric current had a volume of 25 amperes ; also that the battery must not be charged while the lamps were alight. The installation was made complete on September 10th, but very soon complaints were made that the light was not satisfactory. The plaintiffs went down and found that the brushes had given way, although a brush ought to last three or four months. The plaintiffs replaced the brushes, made other repairs, and complained that the engine was running while the lights were burning. The defendants subsequently paid £100 on account of the cost of the installation, and promised to call, but did not do so. Then the dispute arose which resulted in this action. The installation was not a success, because the defendants had to use gas ; but the question for decision was to what this want of success was due. Was it a defect of installation, in which case the plaintiffs were responsible, or was it a consequence of the mode of running the machinery, for which the defendants were responsible ? He had asked himself, as a medical man would in a case of illness, what were the symptoms in this case ? They were the destruction of the fuses, the breaking of the filaments, the blackening of the lamps, all of which were consistent with the same cause, namely too much energy, too much current, arising from there having been an overrunning of the engine. There was no mechanical defect imputed to the machinery ; and although no doubt the defendants had the greatest desire to do what they ought for the proper working of the installation, he believed that they did really and truly charge too heavily. Without pledging himself to perfect accuracy in his description of these scientific matters, he said without hesitation that the want of success in this instance was due to some other cause than a defect in the installation. There must therefore be judgment for the plaintiff company both on the claim and the counter-claim.

NOTES.

Burmah.—It is announced that telegraphic communication with Shwegyin has been restored.

Appointment.—M. Angel Mansi has been appointed the Spanish Director-General of Posts and Telegraphs.

The Brazilian Submarine Telegraph Company.—The traffic returns of this company for the week ended 25th December amounted to £2,605.

Cable Work in Italy.—We have received from M. Salvatore Raineri a pamphlet, with full description of the projected cables between Naples and Palermo.

Personal.—M. Fontaine has been made Judge of the Tribunal de Commerce de la Seine.—Mr. Jas. Swinburne has joined the staff of Messrs. R. E. Crompton and Co.

Electricity and Mining. — Electrical transmission of power has been resorted to during the current year in several mines of the Continent, and in each case with satisfactory results.

The Telegraph Battalion.—The section of the Telegraph Battalion of the Royal Engineers from the Cape will be quartered at Aldershot, instead of at Chatham, as previously ordered.

Geographical.—Our esteemed contemporary, *Electricité*, speaking of the Australian telegraphs, says that telegraphic communication between "Adelaide and Pesth" was established in 1877 !

The Crystal Palace.—We learn that the illumination of the Palace by the tens of thousands of tastefully arranged lamps, and by electric light, which has been so attractive a feature of the autumn months, will be extended and continued nightly.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 25th December were £2,052, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

A New Light.—Advices from Vienna state that experiments are being made, at Professor Lieben's chemical laboratory, with a new gas light invented by Dr. Auer. A cotton wick, saturated with an incombustible metal solution, is introduced into the flame of an ordinary Bunsen lamp, the result being a light similar to the incandescent electric light.

Another Electric Railway.—It is announced that the Swiss Government have granted a concession to a firm of electrical engineers at Geneva for the construction of a railway up Mont Salève, near Geneva. The line will be laid with a central rack, like that of the Righi railway ; but the toothed pinion of the engine which gears into it will be driven by electricity instead of by steam.

The Eastern and South African Telegraph Company.—This company announces that the coupons due on 1st instant on their Five per Cent. Mortgage Debentures will be paid on and after that date on presentation of the same at the banking house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

Windsor.—At Windsor the erection of a new post office has been commenced by Her Majesty's Office of Works at the corner of St. Alban's-street, in the vicinity of the Royal Mews. The building will be of handsome Elizabethan design, with red brick facings and white stone dressings, and will contain commodious money-order and telegraph offices and sorting rooms with yard for the reception of the mail carts.

Too Patent.—A Washington stove dealer, it is said, invented a house telephone, a simple little contrivance, making use of gas and water pipes instead of wires, attached to which in each room was a transmitter and receiver. But he was informed that his machine was an infringement of the Bell, though he used no electrical current, and he has abandoned his intention of making a business of furnishing these instruments in houses.

H.M.S. "Pylades."—An important addition has been made to the active list of the Royal Navy by the completion for sea at Sheerness Dockyard of the new unarmoured composite corvette "Pylades," which was launched from the building slip on the 25th November, 1884. In addition to her other armament, the "Pylades" is also equipped with Gardner and Nordenfelt machine guns, and the electrical apparatus for discharging the spar torpedo.

Photographs of Lightning.—At the meeting of the Franklin Institute last month, Prof. Houston presented two photographs taken on a dark night by the light produced by flashes of lightning, in which a building and trees were distinctly shown. They were thrown on the screen by the aid of Prof. Holman's lantern miscroscope. The duration of the flash by which the plates were secured was estimated at the one three hundreth part of a second.

The Soudan Telegraphists.—At Aldershot, on Saturday, Colonel Mainguy presented a number of officers and men of the Royal Engineers on Church parade with medals and clasps for the late campaign in the Soudan. Some of the recipients had formed part of the Nile Expeditionary force, and others were employed between Suakim and Korti. The Colonel spoke in complimentary terms of the excellent work performed by the Telegraph Section.

Honours.—The Queen, it is announced, has been pleased to confer the honour of Knight Commander of St. Michael and St. George on Colonel Bateman-Champain, well known in connection with Anglo-Indian telegraph enterprise. It is also announced that George Edward Paget, Esq., M.D., F.R.S., Regius Professor of Physic in the University of Cambridge, has been appointed to be an Ordinary Member of the Civil Division of the Second Class, or Knights Commanders of the Most Honourable Order of the Bath.

Interruption to Telegraphic Communication. — A singular accident occurred at Newbury on Saturday afternoon, resulting in the interruption of telegraphic communication between the metropolis and Bristol and other places in the West of England. A large walnut tree was being removed by a traction engine from one part of Newbury to another, and when passing through Northbrook-street the branches caught the line of wires which cross that thoroughfare and snapped them. The damage will be repaired with as little delay as possible.

Transmission of Power.—In a short article relating to the electrical transmission of power, M. Hospitalier comes to the conclusion that to M. Marcel Deprez must be given the honour of being the pioneer in the application of electricity for this purpose. We are under the impression that neither the idea nor the actual testing of the idea is as recent as the Vienna Exhibition of 1875. Speaking for the moment from recollection, we are under the impression that a number of patents between the years 1840 and 1860 deal with the utilisation of electricity for the transmission of power.

The Electric Lighting Act.—Referring to the compulsory purchase clause of the Electric Lighting Act, the *Building and*

Digitized by Google

Engineering Times says:—"The question raised seems to be whether the period of twenty-one years is sufficiently long or not; for that Parliament will refrain from imposing any limit at all is not to be expected. That the period at present specified is insufficient to encourage the development of electric lighting upon any extensive scale is, we think, sufficiently evident from the tardy progress it has made in this country as compared with what has been done on the Continent and in America.

MUST PAY.—An American contemporary says a new device has been invented for telephone stations. It is so constructed that a person wishing to use it enters a box, and on depositing a nickel in the fare box a clock indexes his entrance, and he is permitted to occupy the box five minutes. At the expiration of that time he must leave the box, or, if he remains, he must pay a second fare. Should he decline paying the fare he is bolted within, and the machine telephones the fact to the central office. Then he must remain until released by a messenger from said office. These boxes are designed for cigar shops, drug stores, and such places accessible to the public.

THE EDISON PATENT IN CANADA.—The taking of evidence before the Deputy Minister of Agriculture, on the application of the Telephone Manufacturing Company of Toronto, has been concluded and decision reserved. The application is to have the Edison telephone patent, now held by the Bell Telephone Company, declared void because of the importation, non-manufacture, and refusal to sell by the Bell Company. The Bell patent proper was annulled last year, but the Edison patent still holds good, and, as the Bell Company has brought an action against the Telephone Manufacturing Company for an infringement of the last-named patent, this application is made to set it aside.

A NEW METHOD OF PROPULSION.—The idea of propelling ships by forcing water out of pipes sternward has, as is well known, been put in practical application. An analogous method, which consists in forcing gases against the water, and thus establishing a means of propulsion, has been devised in Brooklyn, U.S.A. The system will, we are advised, soon be given a practical trial, the ship with which it is to be made having recently been launched. The method employed, briefly stated, consists in compressing a small quantity of air, which is then impregnated with petroleum spray. This is then exploded by an electric spark, and the large volume of gas generated is forced out at the stern.

THE NATIONAL TELEPHONE COMPANY.—From the December list of subscribers of this company in the Edinburgh district, we learn that each subscriber to the exchange system has a wire, bearing a number, running from his own office or residence to the company's nearest exchange or operating room. These exchanges, of which there are now four in full working order throughout Edinburgh and Leith, are connected together by cables, or trunk lines, and each exchange is provided with a switching apparatus, by means of which the operators in attendance can connect any two wires with each other, answer calls, and ring up subscribers. The exchanges are open day and night, and on Sundays.

ELECTRIC RESISTANCE OF ALCOHOL.—At the meeting of the French Physical Society, on December 4, M. Fousserau read a paper upon the Electric Resistance of Alcohol. His measurements have been obtained by Lippmann's method, and the arrangement was similar to that adopted in his experiments upon distilled water, &c. The resistance of commercial alcohol at 15°C. was found to be between 2·47 and 3·38 meghoms. Experiments were also carried out upon a mixture of alcohol and water. The resistance of these mixtures was generally found to be between that of alcohol and that of water, the minimum resistance being, for the mixture, three of water and one hundred of alcohol. M. Fousserau found that it was necessary to vary considerably the proportion of water in order to obtain an appreciable change in the resistance of the mixture.

PROPOSED TELEPHONIC EXCHANGE AT STIRLING.—A meeting of gentlemen interested in a proposal to institute a telephonic exchange in Stirling was held recently in the Golden Lion Hotel. Mr. A. R. Bennett, General Manager of the National Telephone Company, addressed the meeting on the utility of the telephone as a business adjunct, and explained that the proposed exchange would afford communication in the meantime with the subscribers within a six miles' radius from Stirling, the intention being afterwards to extend the communication to Glasgow, Dundee, Perth, &c. Mr. Mitchell Thomson, Edinburgh, a Director of the Company, also addressed the meeting. At the close a number of questions were put and satisfactorily answered by Mr. Bennett. On the motion of the chairman, votes of thanks were awarded to Messrs. Bennett and Thomson. A considerable number of gentlemen signified their willingness to join the exchange.

THE ELECTRIC LIGHT AND GAS COMPANIES.—Our readers are aware, says a contemporary, that the Imperial Continental Gas Association have undertaken the supply of electricity in Vienna. Another instance of an electric light installation being undertaken by a gas company is that of the Anglo-Romano Company, who are establishing electric lighting plant for illuminating several public and private buildings in Rome with a total of 12,000 incandescent lamps, 1,500 of which are expected to be in working order by May next. For the purposes of this installation, two self-exciting alternate-current dynamos, each to yield a current of 35 to 38 amperes, at a potential of 1,800 volts, are being prepared, one of which will serve as a spare machine. These dynamos will be driven by steam engines mounted on a common shaft with the respective dynamos. The electric lighting plant will be erected in the company's works, and the current will be conveyed to a maximum distance of about two miles.

THE ELECTRIC LIGHT IN KIMBERLEY, SOUTH AFRICA.—The illumination of the Kimberley Gardens and promenade concert which took place recently was the final item on the list or programme of festivities in connection with the opening of the railway to Kimberley. The arrangements for lighting the grounds by electricity were perfect, and reflected the highest credit on the energy of the borough electrician, Mr. R. L. Cousens. One lamp was erected near the cricket club's pavilion, and six more were fixed up under the trees and in the centre of the grounds. The electricity was generated by means of the spare machine taken from the Electric Light Works at the Compound to the workshops of the United Diamond Mining Company, where it was driven by that company's engine. The engine was a 25-lighter, fitted with an automatic regulator. The shifting of the wires, lamps, and supports had all been performed within four days, and at the same time the lights in the town, to the number of 46, had to be kept burning.

LIGHTING AT THE NEW THEATRE, BRUSSELS.—The Theâtre de la Bourse was opened on Thursday, 30th December, by an entertainment, the gross receipts of which were given to the poor of Brussels and the adjoining parish of Molenbeek-Saint-Jean. The lustres are designed by the architect, M. Chambon, to suggest the jewels hung from the roof of an Indian temple. They have also been arranged for

Digitized by Google

gas or electric light at pleasure, so that, if so desired, the two illuminants may be used alternately. It was intended that the lighting should be by electricity; and M. J. De Luyck, who is both builder and proprietor, had agreed with one of the Brussels companies for the entire lighting, at a cost of 800,000 fr., or £8,000, when the negotiations fell through on his requiring a guarantee of non-extinction, which the electrical company was unwilling to accord. To lend additional *éclat* to the ballet of "Nina," which, by the way, is a London production, M. Emile Closset, constructor of the Melsens lightning conductors, has provided six 500-candle arc lamps, of which two are Foucault regulators and the rest hand-worked, fed by 360 Bunsen batteries of 60 couples each.

Circular Electric Bells.—The Kinetic Engineering Company are manufacturing a circular electric bell which has some commendable features. The electro-magnet and armature are of carefully annealed soft Swedish charcoal iron, and wound with the best silk-covered copper wire, having a conductivity of 98 per cent., and the whole apparatus is both well made and cheap. The hammer spring is of such form and so arranged with regard to the armature that, when the latter is attracted to the electro-magnet poles, the elasticity of the spring carries the hammer on to the gong, so that the latter is always struck, and with proper force, even though, through accident or otherwise, its position may have considerably altered. It is believed that this is the only circular bell in the market in which even the slightest shifting of the gong does not necessitate re-adjustment and regulation. A screw and slot arrangement at the back of the case enables a rough adjustment to be effected once for all when the bell is first put up, and no delicate adjustment or regulation is afterwards required, even although the bell be subjected to very rough usage. The general appearance is graceful, and readily lends itself to artistic decoration.

The National Telephone Company.—The directors and staff of the Yorkshire District of the National Telephone Company gave a ball on Monday evening, the 21st inst., to the lady operators and other friends at the Technical College, Bradford. Amongst those present were Mr. G. A. Steinthal and Major W. H. Shepherd (Directors), Major A. W. Jassen, Mr. and Mrs. A. Philipp and Mr. C. Philipp, Mr. J. C. Chambers (General Manager of the Company) and Mrs. Chambers, Mr. and Mrs. Michael Mullen, Mr. and Mrs. Walter Emmott (Halifax), Mrs. Frank Lumley, Mrs. W. J. Gray (Dewsbury), and Miss Marion Whitehead (Manchester). The following gentlemen acted as stewards:—Mr. J. Lumley, manager of the company's Bradford District; Mr. Ralph Mewburn, manager Leeds District; Mr. W. J. Gray, manager Dewsbury District; Mr. C. Ball, cashier; and Messrs. W. J. Davison, and J. Holroyd, inspectors. The reception room, ball room, and galleries were tastefully decorated with evergreens and drapery, whilst the band was screened from the ball room by a beautiful arrangement of foliage plants. Dancing commenced at nine o'clock and was continued until twelve o'clock, when a supper, provided by the Bradford Café, was served. After supper several ladies and gentlemen went through a programme of songs and recitations, which were much appreciated. After this dancing was resumed, and continued until after three in the morning.—Mr. Michael Mullen, shortly before the conclusion of a very enjoyable night, proposed a vote of thanks to the committee and to the givers of the ball for the entertainment so splendidly provided, a motion which was seconded by Mr. H. Storey, and carried unanimously.—Mr. Lumley, who responded in the absence of Mr. Chambers, said that he trusted this was the first of a series of such annual assemblies.—The music was provided by Mr. Stocks Hammond's band.

Electric Lighting at Leeds.—The Electric Lighting Committee of the Leeds Corporation have decided to illuminate the Victoria Hall by means of arc lamps, at a cost of about £450. Secondary batteries, by the Electric Power Storage Company, are to be provided, and these will be charged by dynamos which the Corporation already have in its possession in the basement of the Municipal buildings. The current is to be carried from the Corporation Offices to the Town Hall along a subway now existing in Calverley-street, and thence into the "false" roof of the Victoria Hall, from which will be suspended eight arc lamps with ornamental pendants. A small sub-committee visited Manchester to see several lamps tried, and they made selection of what is known as the Brockie-Pell, which is said to burn very steadily. Each of the eight lamps will be of 2,000 candle-power. As the electroliers, by means of which the Victoria Hall was lighted by Messrs. Crompton and Co. on the occasion of the last musical festival have not been removed, only a portion of the new arc lamps will be fixed to begin with. It is intended at the outset to hang two of the arc lamps in the middle of the hall, early in January, and before the scheme is completed the committee, and, possibly, the public, will be afforded an opportunity of witnessing the effect produced. The pair of 12 horse-power (nominal) Otto gas engines, by Crossley Brothers, which supply the dynamo power for illuminating the Municipal Offices are at present standing idle all day, so that by the making of a battery installation for the Victoria Hall the corporation will not require any additional engine power, but will be able to fully utilise that which they already have, without extra outlay upon machinery. The two engines are coupled, so that should one dynamo break down, the whole of the power can be run upon the other dynamo, the loss being thus nearly all compensated for. The preparations for putting the committee's project into execution, which are being carried out under the superintendence of the borough engineer's department, are approaching completion, and when the lamps come to hand they will be put in position and set going without delay.

The Stock Exchange.—From time to time we have noticed the proceedings of the Stock Exchange in connection with the Exchange Telegraph Company's work, and we now reproduce the following letter which appeared in the *Times* of Thursday over the signature "F.":—"Sir: The electrical transmission of Stock Exchange prices by means of the Exchange Telegraph Company's recording instruments is a public convenience so well established and so widely recognised that any interference with the 'tape' on the part of the Stock Exchange requires explanation. Permit me, then, to say something as to the motives and intentions of those members of the Stock Exchange who are petitioning the committee in the memorial, the text of which I enclose. In the opinion of the signatories 'outside' agencies for dealing in stocks and shares are no less injurious to the public than to the Stock Exchange, and they consider. therefore, that the Stock Exchange would only be discharging its obvious duty if, in the exercise of its undoubted right, it took steps to discourage them. The Stock Exchange is, and ought to be, not a close, but a regulated corporation, and the public will approve its action in refusing to extend its market to those who are not bound by its rules and regulations. It is to the instantaneous communication of Stock Exchange prices to persons who deal on the strength of them without being amenable to proper control that the development of

REESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA

'outside' business in its most mischievous form is directly due. Without the transmission of instantaneous prices the market must remain with the Stock Exchange, and the 'bucket shop' must cease to exist. The Stock Exchange does not object to the 'tape.' It has everything to gain and nothing to lose from publicity, which brings business by inspiring confidence. Not can it have any possible objection to the public getting its prices so long as it gets the custom which such prices induce. But while the 'tape' is thus desirable for the Stock Exchange. the Stock Exchange is indispensable to the 'tape.' Note well that what the Exchange Telegraph Company wants is the instantaneous price, and it is precisely this which the Stock Exchange can withhold if it sees fit. Reliable and systematic prices can only be obtained from a member, who, having the *entrée* to the market, makes it his business to collect and communicate them, and it is not only in the power of the committee to forbid this, but, if such prices are to be purveyed for the benefit of outside irresponsible agencies, it is its duty to do so. The Exchange Telegraph Company cannot afford to be reduced to obtaining prices in a furtive and haphazard way, and there is every reason to believe that they would readily accede to a proposal from the committee to cut off outsiders if such were made. Indeed, they voluntarily offered to do so some time ago, but for some inscrutable reason the committee declined the suggestion and returned evil for good by requiring them to remove their transmitting instrument from the inside to the outside of the door. This was, to say the least of it, a mistake. The Stock Exchange should extend not less, but more, facilities to the Exchange Telegraph Company. Why should it not install them on the floor of the house, where there is now plenty of room, and enable them to transmit from thence not only prices, but announcements of 'business done,' as they are handed in, and of challenges by brokers wishing to deal in out-of-the-way securities? By this means the Stock Exchange would be at once improving the market they offer the public and furnishing them with more complete information regarding it. Obviously the proper course is not to kick out the 'tape' but to invite it inside on proper terms. We say, therefore, that the Exchange Telegraph Company shall have our prices, but only on the understanding that they are supplied to such persons as shall have previously obtained the license of our committee to receive them, and to no others."

THE TELEPHONE SERVICE IN LIVERPOOL AND MANCHESTER.—A special meeting of the Council of the Liverpool Chamber of Commerce was held at the offices, Exchange-buildings, recently for the purpose of hearing a deputation from the Lancashire and Cheshire Telephone Company. The Telephone Company was represented by Mr. C. Moseley, of Manchester, chairman of the company, Messrs. G. H. Robertson, and Mr. F. W. Reynolds. The secretary of the council read a letter which had been written to the company a short time ago, asking that the rates should be reduced, on the ground that with the exception of London, Manchester, and Liverpool, the telephone charges in the United Kingdom ranged from £10 to to £14. On the Continent the general charge was rather over £7, and in no instance exceeded £10 per annum. It was understood also that the Post Office authorities were prepared to give a large body of subscribers equal facilities to those given by the company for £14. 10s. per annum. As regarded the inefficiency of the system, although some improvement had been made in the working of late, it was found that they were often cut off in conversation, without due notice; that they were frequently connected with wrong numbers; that there was want of proper attention in the switch room, and there was a want of civility; that there were disturbing noises; that communication with Manchester and Ashton was so bad that telegrams were sent in preference. Mr. H. Glasgow said when he consented to adopt the telephone in Liverpool an inducement was held out to him that when they got 200 subscribers the cost would be reduced to £10 a year, but now it was said, owing to various causes, this could not be carried out. Mr. Moseley, in reply, said with regard to communication being cut off, this was one of the most difficult things they had to contend with. He believed it arose from currents in the atmosphere or in the earth. And there might be other causes, such as contact with neighbouring wires, or a little electric leakage. The whole process was of such a delicate nature, and was influenced by such minute currents, that these things were uncontrollable at present. As to delay, this arose from various causes which were beyond their control. With regard to being put on the wrong number, they knew that in listening through a telephone it was very difficult sometimes to distinguish numbers, and even words had often to be spelt. A more serious matter was the complaint of incivility, but this could not be dealt with unless some one would notify it when it was found. With regard to distracting noises, this was one of the difficulties which science had made no remedy against. In reference to the communication between here and Ashton, the fact was they had only lately been able to extend an arm of their business to Ashton, with a single wire between Manchester and Ashton, and this was insufficient for the wants of the public, but they hoped to extend their service in that direction. As to the rates charged, he quoted towns on the Continent and in America, where the charges were higher than in Liverpool. In England the companies had to pay a tax to the Government, which came back on the subscribers, but the most serious part of the letter was the reference to the Post Office. Now, it was well known that the Post Office limited the service for £14. 10s. to a radius of a quarter of a mile, and the charge was increased in proportion to distance. The company were as anxious on behalf of the public as they were on behalf of the shareholders, but they must make such a charge as would give the shareholders a fair return for their money. They were paying now 7 per cent., but they had no reserve fund to replace the plant, and they must have that before they could be justified in making a reduction in the charge. The company were desirous of doing all they could to secure the thorough efficiency of the service. Some discussion followed as to details, after which Mr. Moseley was thanked for his statement, and the meeting then broke up.

WESTERN TELEPHONE COMPANY.—*The Western Morning News*, in a recent issue discussing the position, history, and prospects of this company, among other things, says, "The first telephone erected for practical use in the Western Counties was to connect the office of the *Western Morning News* with the residence of its editor. There are exceptional reasons, from Governmental interference, that have caused England to be behind other countries in the use of the telephone. [We demur somewhat to this statement and the inferences drawn from it following.—ED. *E.*] It seems but yesterday the newspapers announced (in 1877) to an incredulous public that a discovery had been made which enabled persons at a distance to talk with each other by means of electricity. It seemed almost absurd to suppose that the vibrations of the air caused when a person speaks should set in sympathetic vibration a sensitive diaphragm in the same way that they act upon the tympanum of the ear; that then those vibrations should be carried along an electric conductor and be reproduced on another diaphragm a long way off, thus rendering audible sounds spoken at the original source. After being closed by the Government for a

Digitized by Google

short period, the Telephone Exchange was again opened in Plymouth on 18th December, 1884. In April of the present year a new company was formed, which took over all that was left of the old United Telephone Company, and started as the Western Counties and South Wales Telephone Company. Since then it has been bravely fighting against fortune, not so much on account of its only competitor, the Post Office, but on account of being heavily handicapped by that competitor. When the Post Office authorities closed the United Company they opened one of their own, and gave a promise to their subscribers that they would not license any other company or persons in the three towns for five years; and on that undertaking many firms pledged themselves by contract to become members for the five years. When, however, Professor Fawcett removed the restrictions, as already intimated, the promise of the Post Office came to naught, and the subscribers found themselves in the same position as if the Post Office had been guilty of a breach of agreement, as, indeed, strictly speaking, they had been. There are, therefore, two exchanges in this district, and it is pretty certain that one will have to go the wall. There can be little doubt that until the Post Office decides to do all the telephonic business of the country itself, it will really do little at all. Government never can, or rather never does, manage anything properly until the thing has proved such a national convenience that it is bound to succeed by whomsoever it is managed; an instance of which inaptitude for ordinary business is shown by the fact that the proprietors of Bell's patent telephone have refused a Government offer of many thousands of pounds for their rights, whereas a few years ago they were offered to Government for a very small figure. In these circumstances the policy of the newly-formed company was very simple. It was to endeavour to obtain on their list of subscribers those that were on the list of the Post Office telephone. The directors have seized the opportunity. They have offered to place on their list, free of charge, the Post Office subscribers until their five years' agreement determines, on the condition that for three years afterwards they become paying subscribers at the ordinary rates. The result is that there are on the company's list for the three towns ninety-five subscribers, and when this number is increased to two hundred, the company will keep their exchange open all night without any extra charge. This in itself would be a great advantage to all concerned; but the company does not stop there. They promise that if Government will remit the ten per cent. on the rental they now charge, or will make merely a nominal charge as a recognition of their rights, then the subscribers shall have the benefit of that remission by a reduction of ten per cent. in the rate of subscriptions. This is a consummation devoutly to be wished, and all the pressure that it is possible to bring to bear upon the authorities ought to be exercised as vigorously as possible."

THE ELECTRIC LIGHT IN CHELSEA.—Mr. Charles Mossop, chairman of the Electric Lighting Committee, and Mr. G. R. Strachan, surveyor to the Vestry of Chelsea, have made a report to the Vestry on this subject under these circumstances:—The Chelsea Electricity Supply Company having deposited with the Vestry a copy of the Provisional Order for which they are making application to the Board of Trade, and which, if confirmed by Parliament, will authorise them to erect and maintain electric lines and works and to supply electricity within the parish of Chelsea, the Vestry referred the whole subject to the committee. The gentlemen named above prepared a report, which was adopted by the committee, and on being submitted to the Vestry recently was approved by that body. The report states:—"The undertakers seek compulsory powers over that part of Chelsea included between Elizabeth-street, Exeter-street, and Cadogan-place on the north, and Ovington-street, Halsey-street, Cadogan-terrace, Draycott-place, Lower Sloane-street, and Little George-street on the west and south. This area includes Cadogan-place, Cadogan-square, Hans-place, Lennox-gardens, Sloane-square, and the Court Theatre, and is known throughout the order as Schedule A. Within three years from the commencement of the order, distributing mains for general supply are to be laid in the following streets:—Cadogan place and terrace, Cadogan square and street, D'Oyley-street, Draycott place and street, Elizabeth-street, Ellis-street, Grove-place, Hans-place, Lennox-gardens, Little Cadogan-place, Lower George-street, Milner-street, Pavilion-road, Pont-street, Sloane square and street, Walton place and street, York-street. At the expiration of the three years the undertakers must, on requisition, lay down mains in every other street in the area described. The capital of the undertakers for the purposes of this order is to be £100,500. If the order sought is granted, the owner or occupier of any premises within 25 yards of a main will be entitled to a supply of electricity during the whole or any part of the day, if he pays for so much of the service lines as lies beyond 30ft. from the main, and enters into an agreement to pay for a minimum supply of £14 a year for two years. He must also give security and provide proper apparatus on his premises. The maximum supply to which any single consumer will be entitled is at the rate of 1-24th of a unit in one minute. This limit, if used by any person, would make his lighting bill over £900 a year, and thus it is sufficiently ample. The owners or occupiers of premises not within 25 yards of a main, but which are in Schedule A or its additions, will be entitled to a supply of electricity if two or more of them enter into an agreement to pay for such a supply for three years as will produce an annual sum at least equal to 20 per cent. on the cost of providing the additional mains. The undertakers will be entitled to charge for a supply by any of the following methods:—1. By the quantity of energy in the supply. 2. By the quantity of electricity supplied. 3. By the number of hours during which the supply is used. 4. By agreement. The maximum price is 10d. per unit. In the Brush order it was 7d. per unit, and in the order before the committee last year it was 1s. per unit." The committee came to the conclusion that a modification of the stringent purchase section of the Electric Lighting Act, 1882, is necessary, if electric lighting is to be secured to the public at the present time. They, therefore, had conferences with the promoters, and prepared a clause in lieu of Section 27 of that Act, the effect of which will be as follows:—To give the company 35 years' purchase instead of 21. To authorise the local authority to pay to the undertaker "for all lands and buildings belonging to, and for all materials in store within such jurisdiction necessary to such undertakers for the purposes of their undertaking within such jurisdiction, such a price as would be paid by a willing purchaser to a willing seller in the open market; for all works, machinery, and plant not included in the above, the fair market value of the same, as necessary and in use for such generation and distribution. Such values to be in case of difference determined by arbitration. And in neither case shall any allowance be made for compulsory sale, nor in the basis of calculation of such values shall the actual or future profits of the undertaking at the time of sale be taken into consideration." The promoters of the undertaking have agreed with the Vestry upon the form of the order indicated in the foregoing report.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 107.)

A network of linear dielectric conductors, or of shunted condensers.

Let any number of points be connected by linear conductors, thus forming a network of any degree of complexity. They will be referred to as Branches. Let each branch consist of any number of conductors in sequence, to be called the Shunts. Let every shunt have its ends joined to the poles of a condenser by wires whose resistances we do not count. This makes the combination complete. We have a linear combination of inductive branches exactly similar to the conductive; they are side by side, as it were, and in connection at certain points. We may regard the conductors as shunts to the condensers, or the other way, as we please, but the former plan is perhaps the best.

Instead of thus shunting the condensers by external conductors, we may do away with the shunts, giving instead equal conductances to the condensers themselves, thus making a combination of unshunted leaky condensers.

Or, we may abolish the external condensers, and give equal dielectric capacity (uniformly distributed *in* the wires) to the former shunts themselves, thus making a network of dielectric conductors. The theory is in all cases the same, with certain exceptions as regards the effects of impressed force and of electro-magnetic induction. In many respects the theory is most simply expressed by having the two qualities, conductivity and dielectric capacity, coincident, as in the dielectric conductors, instead of side by side, as in the case of the shunted condensers.

If the shunted condensers were all disconnected from one another so as to form independent circuits, partly conductive and partly dielectric, any charges they might have would discharge through their shunts, each charge at its proper rate depending upon the time constant of the condenser concerned, which is rp, if r be the resistance of the shunt and p the capacity of the condenser (inertia is ignored). When they are in connection, as above described, the time constants of the normal systems will all lie between the greatest and the least of the time constants of the separate shunted condensers. If these be all equal, there is but one time constant, viz., the common value of rp. In this case, if the condensers be charged in any manner and then be left in connection without impressed force anywhere in the system, the charges will at once readjust themselves to a new distribution, to be found by the two considerations that the E.M.F. in any circuit in the new state is zero, and that the charges that disappear form a system of closed displacement in the combination. This new state will then subside uniformly everywhere, each condenser discharging through its own shunt. If an impressed force be introduced at the junction of two shunted condensers, say in an infinitely short wire joining one shunt to the next, it sets up the appropriate state of conduction current in the branches and of charge in the condensers instantly; these charges are equal in all the condensers in one branch, and in different branches are simply proportional to the currents in the branches. The same will be true if the impressed force be in a shunt, if there be an equal and similarly directed impressed force in the corresponding condenser. (In the case of the dielectric wires there is no need for this reservation.) But if the impressed force be in a shunt only, the charge of its condenser will be opposite to that of the others in the same branch, and there will be retardation according to the common time-constant. Thus, if the condensers be charged in any manner which could be produced by impressed forces in any of or all the branches (equally in shunts and condensers), and be left to themselves, the subsidence is instantaneous. There is only retardation in connection with those parts of the system of charges which could not be produced in the described manner. And, considering electro-magnetic induction, if it operate equally on conductor and dielectric, as in the case of the dielectric wires, it will only affect the discharge of the parts that before subsided instantly, the subsidence being no longer immediate; whilst the other parts will subside just as before, independently of inertia; for as the conductive and dielectric currents are equal and opposite, there is no true current and no electro-magnetic induction in connection therewith.

The above are conclusions from the general theory in the last section. As regards the proof of the limits between which the time constants must lie, let E be the E.M.F. in any condenser, p its capacity, and k the conductance of its shunt. Then, in any normal system, if Q be the dissipativity and U the potential energy,

$$\Sigma(k+pn)E^2 = Q + 2nU = 0,$$

the Σ to include all the shunted condensers. If n do not lie between the greatest and least values of $-k/p$, the summation cannot vanish, as it must; therefore every n does lie between these limits.

The differential equation of the combination, and the determinantal equation of the rates of subsidence, are most directly found by the method used in the paper on Induction in Cores, when treating of combinations of coils. The sum of the steps of potential in any circuit must be zero; get, then, the expression for the step of potential between any two points in terms of the currents, and we have one equation for every circuit. Eliminate the currents by their conditions of continuity, and the result is the differential equation, or the determinantal equation, according as we treat d/dt as the differentiating operator or as a constant.

In the present case, if Γ be the sum of the currents in a shunt and in its condenser, reckoned the same way in both (or the true current in the dielectric conductor), we have

$$\Gamma = (k+pn)E,$$

if n stand for d/dt. Every condenser has an equation of this form. Here E is the fall of potential through the shunt and through the condenser. Since Γ is the same along the whole of any one branch, the fall of potential between its ends is

$$\Gamma\Sigma(k+pn)^{-1},$$

the Σ to include all the condensers in the branch. Hence, if the combination consist of only one closed circuit,

$$\Sigma(k+pn)^{-1} = 0,$$

when cleared of fractions, is the differential, or the determinantal equation, according as n is d/dt or algebraical. That is, we equate the (generalised) resistance of the circuit to zero. Thus, if there be three condensers, and y stand for $k+pn$, the equation is

$$(y_1)^{-1} + (y_2)^{-1} + (y_3)^{-1} = 0\text{; or, } y_1y_2 + y_2y_3 + y_3y_1 = 0.$$

The determinantal equation of m condensers in one circuit is of the $(m-1)^{th}$ degree; one freedom is lost. The missing root is the negative infinity root of the instantaneous subsidence. To bring it to finiteness, put in the circuit a conductor without condenser. Then *its* y is its real conductance, say k_0, and the equation is

$$k_0^{-1} + \Sigma y^{-1} = 0.$$

This has the full number m of roots.

Let $q_1, q_2, \ldots$, be the charges and E_1 $E_2, \ldots$, be the E.M.F.'s of the condensers of capacity $p_1, p_2, \ldots$, whose shunts have conductances $k_1, k_2, \ldots$, going round the circuit in the + direction of Γ. A charge is + when the displacement is in the + direction. Then we have

$$q_1 = p_1E_1, \qquad q_2 = p_2E_2, \qquad \text{\&c.}$$

or, $$q_1 = p_1\Gamma/(k_1+p_1n), \qquad q_2 = p_2\Gamma/(k_2+p_2n), \qquad \text{\&c.}$$

Therefore, in a normal system, the ratios of the charges are

$$q_1 : q_2 : \ldots = (k_1/p_1+n)^{-1} : (k_2/p_2+n)^{-1} : \ldots = p_1/y_1 : p_2/y_2 : \ldots,$$

and thus we have m sets of ratios, by giving to n its m values in succession. To determine the absolute size of a particular normal system, use $U_{12}=0$, taking $p_1/y_1, \ldots$ as the normal functions. If A be their common multiplier, we get

$$A = (\Sigma Dy^{-1}) \div (\Sigma py^{-2})$$

if D_1, D_2, &c., be the initial charges.

When, by shortening the wire k_0, we send the root depending upon its presence to $-\infty$, the above ratios become $1:1:1:\ldots$

Digitized by Google

in the normal system of this root. Taking, then, 1, 1, 1, as the normal functions,

$$A = (\Sigma D p^{-1}) \div \Sigma p^{-1}$$

gives the common charge of all the condensers that instantly disappears. It is the charge due to the initial E.M.F. in the circuit. Its disappearance makes the electric force polar.

If all the time constants p/k of the separate condensers are equal we have $y=0$ repeated $(m-1)$ times. The charges at time t are therefore

$$q_1 = (D_1 - A)\epsilon_0, \qquad q_2 = (D_2 - A)\epsilon_0, \qquad \text{etc.,}$$

where $\epsilon_0 = \epsilon^{-kt/p}$, and A is given by the previous equation.

So far relating to a single closed circuit, the next simplest case is that of any number of branches uniting two points. Here the sum of the currents leaving either point is zero. If $\Gamma_1, \Gamma_2, \ldots$, be the currents in the branches, all reckoned parallel, $p_{11}, p_{12}, \ldots$, the capacities in the first branch, $p_{21}, p_{22}, \ldots$, in the second, with a similar notation for the other quantities, we have

$$\Gamma_1 = (k_{11}/p_{11} + n)q_{11} = (k_{12}/p_{12} + n)q_{12} = \ldots,$$
$$\Gamma_2 = (k_{21}/p_{21} + n)q_{21} = (k_{22}/p_{22} + n)q_{22} = \ldots,$$

&c., and the sum of the Γ's is zero. These give the determinantal equation.

$$(\Sigma y_1^{-1})^{-1} + (\Sigma y_2^{-1})^{-1} + (\Sigma y_3^{-1})^{-1} + \ldots = 0,$$

each summation to include all the y's in one branch only. That is, the sum of the generalised conductances of the branches in parallel is zero.

The number of missing roots is one less than the number of branches. The full number, equal to the number of condensers, may be got by inserting condenserless conductors in all the branches except one; if in that one also, it makes no difference in their number, though altering their magnitude.

If there be no inserted condenserless conductors, it will be necessary to determine what part of each charge instantly disappears. We have to make the electric polar force, and therefore equalise the E.M.F.'s in the different branches reckoned the same way between the two points, and do it by making equal changes in the initial charges in any one branch. The charges q at time t, after they were given D, are, if k/p is the same for every condenser, given by

$$q_{11} = (D_{11} - A_1)\epsilon_0, \qquad q_{21} = (D_{21} - A_2)\epsilon_0, \text{ \&c.}$$
$$q_{12} = (D_{12} - A_1)\epsilon_0, \qquad q_{22} = (D_{22} - A_2)\epsilon_0, \text{ \&c.}$$
&c. &c.

where ϵ_0 is, as before, the time function of the repeated root, and there is one A to be found in each branch. It will not be necessary to take up space by describing how they are got in this special case, or in writing them out, as the following method, applicable to any combination, will apply.

In any network of linear conductors there is a certain number of degrees of freedom, *i.e.*, the number of branches in which the currents must be given in order that they may be known in all the rest. Thus, in the common "bridge," the currents in three branches being given, those in the rest follow.

[If m points be joined by $m(m-1)/2$ conductive branches, the number of current freedoms is $(m-1)(m-2)/2$. This is $(m-1)$ less than the number of branches.]

This number of current freedoms is just the number of the missing $(-\infty)$ roots in the determinantal equation when the branches have condensers connected along them as described at the beginning. As for the equation itself, if the characteristic function of the conductive combination be known, it may be got by turning every k into $k+pn$ in it, and equating the result to zero. [The characteristic function is of the degree $(m-1)$ in terms of the conductances (one less than the number of points); hence, when for k we put $(k+pn)$, the determinantal equation is of the degree $(m-1)$ in n, so that the roots are fewer in number than the branches by the number of current freedoms in the conductive network, if there be but one condenser in each branch, and fewer in number than the condensers by the number of current freedoms in the conductive network if there be many condensers in each branch. If, on the other hand, there are no condensers, but we take account of the self-induction of every branch, we get the determinantal equation by turning k into $(k^{-1}+sn)^{-1}$, if s be the self-induction coefficient of a branch. There will now be $(m-1)$ fewer roots than the number of branches.] Now, suppose k/p is the same for every condenser, and we want to know how the initial charges subside. Let us number the branches 1, 2, 3, &c., and choose (arbitrarily) a certain direction in each for the positive direction in which the current, E.M.F., and charges (displacements) are reckoned. Let every capacity have two suffixes, the first to denote which branch is referred to, the second to show its position in the branch, and do the same with the charges and the conductances. The currents Γ only want one suffix to show which branch is referred to. We have, then, in the case of the infinity roots, if A_{11}, &c., are the charges that disappear,

$$A_{11} = A_{12} = A_{13} = \ldots = A_1 \text{ say,}$$
$$A_{21} = A_{22} = A_{23} = \ldots = A_2 \text{ say,}$$

&c.; that is, the same portion of the charge of every condenser in one branch disappears instantly. Besides that, $A_1, A_2, \ldots$, in the different branches, are connected together by the same conditions of continuity as the currents in the different branches. That is, $A_1, A_2, \ldots$, form a system of closed displacement.

The solution is therefore of the same form as in the previous equations, and we have only to find one A for each branch to complete the solution. Initially, we have

$$D_{11} = A_1 + (D_{11} - A_1), \qquad D_{21} = A_2 + (D_{21} - A_2), \text{ \&c.}$$
$$D_{12} = A_1 + (D_{12} - A_1), \qquad D_{22} = A_2 + (D_{22} - A_2), \text{ \&c.}$$
$$D_{13} = A_1 + (D_{13} - A_1), \qquad D_{23} = A_2 + (D_{23} - A_2), \text{ \&c.}$$
&c. &c.

The system of the A's is closed. That of the (D − A)'s is such that its electric force is polar. The mutual energy of the latter and any closed displacement is therefore zero. The mutual energy of the D's and any closed displacement is therefore equal to that of the A's and the same. Let this "any closed displacement" be the charges set up in the system by a unit impressed force in any branch (equally in shunt and condenser). For instance, let d_{11}, d_{12}, d_{13}, be the charges of the condensers in branches 1, 2, 3, &c., due to unit impressed force in branch 1. Then the mutual energy of the D's and d's equals that of the A's and d's. But the latter equals twice the product of the impressed force of the d's into the displacement of the A's; or, since the impressed force is unity and is in the branch 1 only, it equals $2A_1$ itself. Hence A_1 is one half the mutual energy of the D's and d's. Or,

$$A_1 = d_{11}\Sigma D_1/p_1 + d_{12}\Sigma D_2/p_2 + d_{13}\Sigma D_3/p_3 + \ldots$$

where the first Σ relates to branch 1, the second to branch 2, and so on.

Similarly, if $d_{21}, d_{22}, d_{23}, \ldots$, are the charges in 1, 2, 3, …, due to unit impressed force in 2, we have

$$A_2 = d_{21}\Sigma D_1/p_1 + d_{22}\Sigma D_2/p_2 + d_{23}\Sigma D_{23}/p + \ldots.$$

Thus the A's are known in terms of initial charges and of the d's. The latter may be found in precisely the same manner as the current in the branches due to the unit impressed forces. In fact, instead of mutual energy, we may employ the idea of mutual dissipativity and activity. Let $\gamma_{11}, \gamma_{12}, \gamma_{13}$, &c., be the currents in 1, 2, 3, … due to unit impressed force in 1. Then

$$A_1 = \gamma_{11}\Sigma D_1/k_1 + \gamma_{12}\Sigma D_2/k_2 + \gamma_{13}\Sigma D_3/k_3 + \ldots,$$

is an alternative form of A_1. In the reasoning we should now imagine the D's to be currents (not closed), and the A's closed currents, and speak of mutual dissipativity or of activity. The matter is therefore reduced to the problem of finding how current due to impressed force in any branch divides through the conductive system. [When the time constants of the condensers (shunted) are not equal, the charges that are left after the first readjustment require to be decomposed into their proper normal systems, to be done by the $U_{12}=0$ property. This does not present anything unusual.]

The following is the tridimensional representative of the above method of finding the A's. Referring now everything to the unit volume, let D_0 be the initial displacement, and p the capacity. Divide D_0 into two parts, of which one is closed, whilst the electric force of the other is polar. That is, let

Digitized by Google

A be the closed displacement, so that

$$\text{div. } A = 0, \qquad \text{curl. } (D_0 - A)/p = 0,$$

find A. The mutual energy of D_0 and any closed displacement equals that of A and the same, because the force $(D_0 - A)/p$ is polar. Let the any closed displacement be that due to unit e at any point, and call it d. Then

$$\Sigma d D_0/p = \Sigma d A/p = \Sigma(e+f)A$$

if f is the polar force of e,

$$= \Sigma e A = \text{tensor of A at the place of } e,$$

if e be parallel to A.

Thus we know the distribution of A as soon as we know the displacement due to impressed force.

(*To be continued.*)

MAGNETISM.

BY WILLOUGHBY SMITH.

(*Continued from page 129.*)

Amongst the foremost labourers in this new field of research was Ampère, who soon discovered that when two metal bodies are suspended or supported so as to be capable of moving either towards or from one another at the time that electrical currents are passing through them, they manifest a mutual attraction or repulsion, according as the currents are moving in the same or opposite directions. This phenomenon Ampère called electro-dynamics. M. Arago, in France, and Sir H. Davy, in England, about the same time made known that if a metal wire, while being traversed by an electrical current, be plunged into iron filings it will retain around it a considerable quantity of the filings in the form of a cylindrical mass, the thickness depending on the strength of the current, and that immediately the circuit is broken the filings fall. This phenomenon further proved the magnetic properties of the wire while under the influence of an electric current. The following notes are from results of similar experiments which I have made in this direction. The current must be of great strength to produce an appreciable effect; for instance, five amperes through a copper wire ·018 of an inch diameter. The larger the diameter of the wire the greater must be the current strength. Two Grove cells were sufficient to produce the effect with a very short length of wire, the greatest weight supported at any part of the wire being about 1 grain. Very fine iron filings settled round the wire, giving it the appearance of a circular brush. Copper, iron and aluminium all gave identically the same results, but with tin, zinc, and lead the necessary current could not be used on account of their low melting point. Arago and Davy also found that a steel needle became more strongly magnetised if the magnetising wire were bent into a helix and the needle placed in the axis of the helix, instead of the conductor remaining rectilinear.

The knowledge of this fact led to discoveries still more startling, for it was soon found that if a rod of soft iron were placed in a helix formed of a wire of any conducting metal covered with an insulating material, a feeble current was sufficient to impart powerful magnetic properties to the iron rod, more especially if the rod were formed in the shape of a horseshoe so as to permit of both ends being used to attract the same substance. The magnetisation was instantaneous, appearing immediately the helix was connected with the battery, and ceasing, almost entirely, as soon as the circuit was broken. Such an arrangement was called an electro-magnet, and this discovery caused a great advance in the science of magnetism, for it furnished a means of acquiring immense, if not an unlimited, magnetic power.

Experimenters soon gave their attention to determining the conditions most favourable to the development of powerful electro-magnets, and the published results of some of their labours are so remarkable that it cannot be deemed unjust to suppose that their ambition to excel each other took possession of their imagination and left their reason unemployed. However, some of their experiments produced very curious, interesting, and valuable results. For instance, it was found that if a helix of insulated copper wire be placed horizontally, and one end of a rod of soft iron be presented at one end of the helix, it will be attracted into the helix, and place itself so that its centre coincides with that of the helix, the result being the same whether the rod is shorter or longer than the axis of the helix. Again, a ball of soft iron of any diameter, providing it is not too large to enter the helix, when placed at the opening of the helix and being free to roll upon a very horizontal plane, in like manner rushes in and stops at the centre. So powerful can the action of a helix of this description be made, that if a magnetised needle or bar be placed within it so as to rest upon the lower portion of the helix, the moment the battery is connected to the helix the needle or bar will place itself in the axis, and so long as the circuit is maintained, remain suspended in the air in opposition to the force of gravity. In the centre of a vertical helix connected with a powerful battery, I have so suspended a rod of iron 3ft. long and 1·25in. in diameter, totally free from any material connection or support.

A helix of insulated wire enclosing an iron core and electrically excited not only makes that iron a magnet, but is itself a magnet, and has a sphere of magnetic lines of force surrounding it independent of the lines of force given out by the iron which it surrounds, and the more intense the current passing through the helix the more intense will be the magnetic lines of force. This should be borne in mind when experimenting with helices or iron rods separately or combined. The law of action and re-action being equal and opposite, it might be expected that, as electricity produces magnetism, so, conversely, magnetism ought to produce electricity. Thus, no doubt, reasoned Faraday, and the results of his experimental research in that direction brought to light several most valuable discoveries. Faraday wound a certain length of insulated copper wire round a cylinder of wood, and over this helix he wound a similar length of insulated wire. One of these helices he connected with a galvanometer, and the other with a voltaic battery; when the battery contact was made he noticed a sudden effect at the galvanometer, and a similar effect when the contact with the battery was broken, but in the opposite direction to the first deflection. This and similar phenomena Faraday called volta-electric induction. He then wound similar lengths of insulated copper wire separately on to sections of a welded ring of soft round bar iron. When one of these helices was connected to a galvanometer, and the battery to one of the other helices, much greater results were obtained than with helices wound on wood. When a charcoal point was fixed to each end of the wire of one helix, and these points were brought close together, a minute spark could be perceived each time contact with the battery was made with one of the other helices. He also found that whenever the end of a magnet was passed suddenly into or out of the centre of a hollow helix of wire connected with a galvanometer, strong deflections were produced, but the direction of the deflection depended on the movement of the magnet. When entering the helix the galvanometer was affected in one direction, and when leaving it was affected in the opposite direction. The same results were obtained if the magnet were fixed and the helix movable. This agency, excited by ordinary magnets, Faraday called magneto-electric induction. Thus Faraday proved that electrical currents can be produced by magnets the same as magnetic effects are produced by electrical currents, but he believed they differed in one important respect, viz., that time is required for the development of magneto-electric induction, whereas he considered volta-electric induction to be instantaneous; but the latter is not borne out by the results of my published experiments on volta and magneto-electric induction. It was while engaged in those experiments that Faraday coined and circulated the terms "line of magnetic force," or "magnetic lines of force," "magnetic curves," "line or lines of electric force," "magnetic or electric fields," &c.

Magnetism has ever been a fertile field for hypothesis, and the discovery of electro-magnetism increased rather than diminished the confusion created by the number of theories that were promulgated to account for so remarkable a phenomenon. If the reasoning of some had been correct, it would have been necessary to have ignored the fact that man cannot create, destroy, or in any way alter the mysterious power with which the Almighty has endowed matter, which power is designated, for the want of more knowledge, gravity, heat, light, electricity, magnetism, and so on.

The analogy which exists between the phenomena of magnetism and those of electricity are such as to warrant the suggested probability that the theory which applies to the one might, with equal justice, be attributed to the other. Thus arose the one-fluid theory of Apinus for magnetism, which is similar to Franklin's theory of electrical induction. The foundation of the hypothesis of two magnetic fluids, which is in many instances similar to Du Fay's two-fluid theory of electricity, was laid by Colomb. Faraday assumed that all the particles of matter were *not* polar in their normal state, but became so by the influence of charged particles when either in contact or in sufficiently close proximity to them, the particles thus polarised being in a forced state, and endeavouring to regain their normal or natural condition. Thus his hypothesis that induction, which always precedes conduction, is an action of contiguous particles consisting in a species of polarity. The great similarity of action between common magnets, electro-magnets, and electric currents furnishes powerful reasons that the action is the same in all cases; consequently the theory which applies the more correctly to the one should apply equally to the other. The further I extend my experimental research either in electricity or magnetism, the more strongly do I become converted to the belief of the correctness of Faraday's views concerning these matters; but I am inclined to differ from him on one most important point, for I assume that each atom of matter possesses in itself all the properties of a magnet,

Digitized by Google

and, consequently, emits its own lines of force; and, I further believe, that the molecular attraction known as "cohesive force" is one of the results of this all-pervading system of polarisation. Each atom existing in a polarised state it follows, I think, that the outer ones, which form the surface of the earth, affect and are affected by the atoms of the air and other atoms in contact or in close proximity to them, and thus the system of polarisation is continued in curved lines throughout the whole atmosphere surrounding the earth, and constitutes what is termed "terrestial magnetism." If this be so, it therefore follows that all particles of matter, solid, liquid, or gaseous, are in a polarised state, and consequently emit lines of force.

These lines arrange themselves so as to be in a position symmetrical to the lines of force emitted by any other body, the earth's magnetic field for instance; that is to say, the strongest polarised lines will control the weakest, and direct and attract them, as illustrated by gravity. But when forced from their normal position of equilibrium by any external agency, it depends on the energy of the same whether heat, light, or sound be developed separately, or the whole three combined, as instanced by the heat generated in a magnetic field, the light produced from it, the hum of the insect or other more significant causes, or the three combined, as in the lightning's flash and the thunder's peal. As soon as the cause of each phenomenon no longer exists, the lines of force regain their normal condition, and all is once more quietude.

All matter conducts electricity, but not in the same degree, in fact it is difficult with some substances to detect their conductibility. With an increase of temperature gutta percha and such like dielectrics decrease in resistance, while with copper and other good conductors their resistance is increased under the same conditions. All matter does not polarise to the same degree; in fact, with our present knowledge of instruments for this line of experimental research, we are only able to speak in positive terms of comparatively few; but with these few we learn that temperature affects polarisation, and perhaps, if sufficient variation of temperature could be obtained, it might be found that, under certain conditions, lines of magnetic force might be made manifest from bodies which at the present time we least suspect. I assume it is not possible to decrease the normal amount of polarisation of atoms, but that it can be increased up to a certain point by external influences, as instanced by the conducting properties of matter, which is, I think, the result of forced polarisation. But if an attempt be made to exceed the maximum specific capacity for polarisation of any combination of atoms forming the material under experiment, then will be developed all the phenomena just mentioned, and eventually, if carried too far, disruption occurs, a phenomenon well known to electricians, and manifested generally in the destructive effects of lightning.

Of course, in a mere pamphlet such as this, it is impossible for me to notice all that has been done by eminent physicists in advancing our knowledge of magnetism. My object has been to give a simple and brief outline, and in so doing to call attention to some of the most prominent points in connection with the history of the same, which, perhaps, might prove of service to the earnest student, in leading up to a better undertanding of the experiments which I am about to describe.

Having now completed my task so far, I will at once proceed to give the results of some experiments I have thought it necessary to make as opportunity offered to assist me in my search after the truth concerning that most wonderful phenomenon of nature which we call magnetism.

Faraday says that a magnetised steel ring shows no external sign of power, because the lines of force of one part are continued on by every other part of the ring; and he instanced this assumed condition, with a view of strengthening *his* hypothesis. But, if such a state of things did really exist, then, in my opinion, the hypotheses I have ventured to bring forward could not be maintained; for, as I understand it, no atom or combination of atoms in any form, animate or inanimate, liquid, solid, or gaseous, can exist in an unpolarised state or without possessing magnetic lines of force. It must, of course, be understood that the external lines of force would be much stronger from a piece of metal in the form of a bar or horseshoe than they would be if the same were made into a continuous ring, assuming each to be polarised to the same intensity. As already intimated, I assume that each atom composing our atmosphere is in a state of polarisation, and is influenced by the magnetic force emanating from the earth. The magnetic lines of force given out by each polarised atom of air in turn affect, more or less, each atom of matter immersed in it; and these atoms in a similar way throw out their own lines of force, and the intensity of these curved lines is no doubt influenced by the nature and form of the material from which the lines emanate. I know of no means by which the accuracy of all such views as these can be experimentally proved unless it be admitted, which I believe to be the case, that the force which is called gravity is the effect of such an universal system of polarisation with which God has endowed all matter.

Iron, especially when in a soft state, is very susceptible of polarisation from the effects of what is called terrestrial magnetism (the polarised atoms of the air); in fact, it is as difficult to keep it from being affected by polarisation as it would be to manipulate a sponge in a liquid without its becoming more or less saturated with it.

In my endeavours to experimentally demonstrate the existence of magnetic lines of force, I generally employed the following very simple but efficient arrangement, which measures the intensity and shows the direction of the lines of magnetic force emanating from "magnetic metals," in a closed ring or in any other form, artificially magnetised, or "unmagnetised," as it is said to be, when it has not been directly influenced by a natural or artificial magnet. This arrangement is shown in Diagram II., in which A represents a short thin steel magnet suspended top and bottom by a single silk fibre in the centre of a small vulcanite or wooden frame. On one side of the magnet is fixed a small thin circular lensed mirror; the magnet, mirror, and method of suspension being similar to that generally adopted in Sir William Thomson's mirror reflecting marine galvanometers, the magnet, mirror, and fibre weighing in all about two grains; B, represents a lamp, or any convenient source of light, so placed that a beam from it will impinge on to the mirror; which reflects it on to a graduated scale, C, placed at the proper distance to receive it in the form of a well defined vertical beam about ·1 of an inch in width and 1·0 in height. The mirror, lamp, and scale should be adjusted so that when the magnet is parallel with the lines of the earth's magnetic force, the reflected beam stands at zero on the scale. In an arrangement of this kind the resistance to its motion presented by the air, and the torsion of the fibre is so slight that the angle of the deflection of the magnet is. as far as could be ascertained, directly proportional to the force affecting the same to any degree within the limits of the scale, and from such delicacy great accuracy is insured. D represents a stand, placed at the back of the magnet, on which the body under experiment is manipulated. This stand should be in no way connected to that on which the magnet is placed, in order that all disturbances from mechanical movements and other causes may be prevented from affecting the magnet. The number of interesting and instructive experiments which can be made by the aid of this simple arrangement will not be apparent at first sight, but as the experimenter proceeds he will find that as soon as he has settled one question to his own satisfaction another will suggest itself.

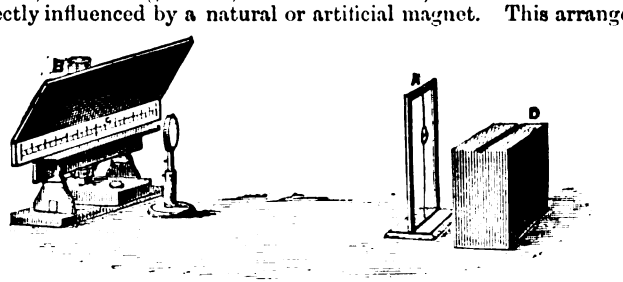

Diagram II.

A rod of annealed charcoal iron 10in. in length and ·31in. in diameter, the length being divided by marks into twenty equal parts, was placed in a groove on stand D, and at a distance of 6in. from the magnet. The positions of both magnet and rod were north and south, consequently they were parallel to each other. The north end of the rod was first placed exactly opposite the centre of the magnet, and the deflection of the magnet noted, the rod of charcoal iron being polarised by the earth's magnetism alone, or, to speak more correctly, by the polarised molecules of air in contact with it; the rod was then slowly moved in the same straight line towards the north, and the deflection noted every time one of the marks on the bar was opposite to the centre of the magnetic needle.

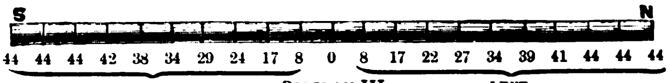

Diagram III.

The results are shown in Diagram III., where it will be seen that at or near the end pointing to the north the deflection produced is at a maximum to the left of the scale, and that, as the rod is moved, the deflection gradually decreases until the centre of the rod is at right angles to the centre of the magnet, when all influence of the rod upon the magnet apparently ceases; but, as the movement of the red proceeds, the magnet becomes again affected, but in the opposite direction, the deflection being to the right of the scale; and it gradually increases until the south end of the rod is at right angles to the centre of the magnet, when the maximum is again reached. Other results observed with this particular specimen of iron showed that the amount of magnetism and direction of polarity induced depended upon the position in which the rod was held; and, consequently, if the position were changed the intensity and polarity were also changed.

(To be continued.)

Retrospect of the Past Year	150	Electricity in Warfare. (Concluded.)	158
		Companies' Share List	160

1885.

A year ago we devoted a considerable space to discussing the why and the wherefore of the position and progress of applied electricity, as well as to recording the work of the year. The time seemed opportune. There were indications of activity, but those indications have not all been realised in actual work. On the whole, however, the candid observer cannot have failed to see great progress—legitimate progress—during the year now past. We do not intend to go over the same ground at present. The time which has elapsed is too short, and the conditions altogether against any startling advance. Company mongers would have us think otherwise; but the company mongers have had their day, and must rest satisfied with their spoil. Never again will the electrical boom be so easily worked as it was in 1882-3. The future student of English idiosyncrasies will be surprised to find on the one hand how vehemently we rail against foreign competition, whilst on the other how easily any foreign dodge empties our pockets. We pointed out a long time ago that the electrical wares for which English capital was asked to pay, and did pay, were almost entirely of foreign extraction. Americans, French, Germans, Belgians—all rushed to make their harvest with the crudest of crude ideas and apparatus. Figures were made to prove anything, and fools subscribed their millions. A host of these parasites is still hanging about desirous of again commencing operations; but we are glad to find that electrical work of all kinds is progressing in the hands of private firms, while it is hardly as successful in the hands of huge companies. There is room and work, however, for two or three such companies, and no doubt the natural process of the survival of the fittest will leave in operation those that are soundly constituted.

The pecuniary harvest, as far as electrical work in 1885 is concerned, has been from few sources. Probably lawyers have gained more out of electrical business than any other class, for scarcely a week has passed but two or three cases have been before the Courts.

Government requirements for ship lighting, and similar lighting for private firms, have kept the Brush Company, Crompton and Co., Johnson and Phillips, Siemens and Co., and the Swan Company, fairly busy in building dynamos, making lamps, and carrying out the installations. Among engine builders who make a speciality of engines for ship lighting, Messrs. Willans and Robinson have rapidly come to the front, and the concensus of practical opinion is that their engines are the best at present constructed for this class of work. Turning from ship lighting to house and street lighting, we find the firms of Davey, Paxman and Co., Marshall and Sons, and Ransomes, Sims, and Jefferies paying close attention to the work and taking the lead so far as engines are concerned. The mention of steam engines brings us to the text upon which this portion of our article hangs. The enormous services of steam are too well known to require description. The present generation, which can hardly imagine a world without steam power, can easily foresee a still further development. In our opinion, whatever be the utility of steam, whatever be its development, it will be ere long—perhaps before the beginning of the next century—altogether outstripped in the race by electricity. The uses to which electricity can be put are numberless, and its help will be more and more widely sought. Luxury and necessity alike go hand in hand in demanding the application of this wonderful agent. There seems to be no single operation in the cycle of the world's works for which its aid cannot with benefit be invoked. Many writers have predicted uses to which it has not yet been put, but neither the wildest imagination of the novelist nor the trained mind of the man of science has been able to give more than a glimpse of the probable value of its future applications. The practical annihilation of space, so far as communication is concerned, is an actual fact. Under oceans, over rivers and mountains, the message is transmitted, so that, if necessary, a drawing room in Antipodean New Zealand may communicate with a drawing room in London. Another application has enabled us to converse through shorter distances; but, as time moves on and conditions are better understood, the distance through which converse may be held will be increased. Then, we hear from time to time rumours indicating that light as well as sound may be brought under control. Outsiders, as a rule, do not in these days of scientific surprises attempt to obtain a knowledge of the rudiments of science; hence the multitude fancies there ought to be little difficulty in controlling light, when we have in some measure harnessed and made subservient the sister phenomenon "sound." When they know or when they recollect that light waves are waves of an imponderable ether, and that sound waves are waves of ponderable matter, they may be able to perceive the difficulties to be overcome before a solution of the problem is found.

Glancing at more prosaic but equally useful matters, a good deal is known as to the possibility of transmitting power by

Digitized by Google

means of electrical apparatus; but the most we can say in this direction is that at present power can only be transmitted economically when the conditions are favourable. Inventors and promoters are straining in the leash to enter into this hunting ground. Hence it is necessary at all times to utter a word of warning to the unwary lest they should be caught napping. The waste energy of Nature may be transmitted and utilised over comparatively short distances, and as the original energy costs nothing, such transmission may be economical. Energy obtained by the combustion of coal, or zinc, &c., is more economical when applied direct than in any indirect manner.

The application of electricity to the giving of light is really in its infancy, though for the past five years it has been the most prominent application. Here we obtain a decided gain in not using directly the light from the combustion of coal. The reasons are not far to seek, and need no recapitulation. The value of the electric light is after a manner admitted, but though admitted it is not understood. Though physiologists have thundered its innocent properties in the ears of the world, the world prefers dirt and the germs of disease to cleanliness and healthiness, because the latter are not immediately and overwhelmingly cheaper than the former. We cannot understand why, when the question of warmth has not to be considered, gas is for a moment tolerated. The electric light is in every way its superior, and even were the annual bill double or treble that of gas, it would be, paradoxical as it seems, by far the cheaper illuminant. This statement refers only to interior lighting.

When we come to street lighting we maintain that, for every reason, we should have more light. Far more business could be done in the busy streets of London at a less cost, so far as horse-flesh and wear and tear are concerned, were there more light. We are glad that the close of the year has seen the arrangement made with the Brush Company to furnish more light to a portion of the City.

Passing onward to other applications of electricity, surely even now their name is legion. By its means we ring our bells, we guard our houses and our safes—or we might do so if we chose; and to do so will, in the not far distant future, be the rule and not the exception. The doctor and the dentist call upon its aid, and it is gradually forcing a greater attention to many of its properties from all medical men. In warfare it is used for signalling purposes, for firing, for training guns, in torpedo work, and in a hundred different ways; in peace it is ubiquitous. Wherever we look we find its use increasing. A grand and at present an almost untrodden field is opening in chemical and metallurgical work. Its possibilities are, indeed, as vast as its operations are wonderful.

The briefest consideration will show that it is of the utmost importance that the younger generation should be well grounded in the fundamental laws which govern this extraordinary agent—that a thorough knowledge of the subject should lead to positions where the remuneration would be ample and the opportunities abundant The watchword, however, should be "thorough." Mediocrity here, as elsewhere, will have to be satisfied with a back seat, while "knowledge" will mean "money." Hand as well as brain must be cultivated, and the result will be satisfactory.

From all points of view the most important part of the telegraphic history of the year is centered round the Berlin Conference. The meeting made a considerable number of alterations, which have not yet come into operation, and the effects of which, therefore, cannot as yet be foretold. In the following paragraphs an attempt has been made to give the salient points of the work of the Conference.

In August last the usual Quinquennial International Telegraph Conference was held at Berlin, where almost every State in the world—excepting the United States and Canada—was represented, and the British Submarine Telegraph Companies were also invited to attend, with liberty to speak but not to vote. The main topic discussed was the tariff for European telegrams, Germany and Austria having proposed the adoption of a low, uniform rate for telegrams sent from and to any country in Europe.

At first blush the proposition approves itself to the minds of everybody unconnected with the telegraph service, the uniform postal rate being of great public convenience; but there is a wide difference between telegrams and letters. Any number of letters may be forwarded with very little, if any, additional cost to the State, but the number of telegrams is limited by the number of telegraph lines, and in the case of cables their capacity will not admit of a sufficient number of words being transmitted at a very low rate to cover the interest on the cost of construction, as well as the charges for maintenance and working.

At the present time the tariff of the submarine cables between all countries in Europe is the same as that of the land lines. Germany's proposition was to make a low, uniform rate by the land lines, and to allow the cables to charge something in excess. The effect of this, if adopted, would have been that the great bulk of the traffic now passing over the cables would have been diverted to the Government land lines, and the public, as well as the European States, would lose the advantage, which it now possesses, of having any number of routes open for the transmission of telegrams at equal rates. The representatives of the companies urged this strongly on the State delegates to the Conference, and the position was recognised, the uniformity of tariff was abandoned, and new rates were arranged, all of them something, and in some cases very considerably, less than those now in force, applicable both to the cables and the land lines.

The cumbersome "grundtax," or initial charge of five words, which the English and French public know nothing about, but which is general in other countries throughout the Continent, was abolished, and the word rate pure and simple agreed to.

The Conference was so much engaged on the question of tariffs that very few changes were made in the regulations which govern the telegraph service; these changes may be summed up in a few words.

At the present time code telegrams exchanged between two places in Europe must be composed of one language; after the 1st of July next they may be written in any one or more of the eight languages which are now admitted for telegrams exchanged with places out of Europe. The present rules of counting and charging extra European telegrams were not altered, but the Conference decided to strengthen the hands of the administrations in exercising their right to demand the production of the code books used by merchants in order to verify the authenticity of the words employed, many firms being accustomed to use irregular combinations which give great trouble to transmit, and deprive the administrations of a considerable portion of their legitimate revenue.

The Conference also made a new regulation, giving greater facilities for refunding the charges for service telegrams sent to obtain the repetition of words unintelligible or supposed to be mutilated in transmission.

It decreed that, unless otherwise directed, all telegrams should be sent by the cheapest route; but the Conference did

Digitized by Google

not withdraw the privilege of sending telegrams by any special route desired by the sender.

In extra European telegrams, at the present time, words containing more than ten letters are charged for as two words. This becomes a hardship when the sender wishes to address his telegram to a place requiring more than ten letters to express it, such as "Buenosayres," "Constantinople," or "Pietermaritzburg." A new regulation was introduced allowing the name of the office or country of destination to be counted as one word, irrespective of the number of letters employed to express it.

The Conference supplemented the present regulations with respect to "urgent telegrams," a class of telegrams widely used on the Continent, but unknown in this country. Urgent telegrams are those which take precedence of all others, except State telegrams. They are especially cared for, and in return for this they bear a tariff equal to three times that of an ordinary message.

The labours of the Conference were completed by numerous minor matters of detail, important in themselves, but not worth enumeration in this place.

The President was able to notify the adhesion to the convention of the colonies of Tasmania, Senegal, and Tunis, making a total of forty Sovereign Administrations which accept the rules adopted at Berlin.

The Eastern and the Indo-European Telegraph Companies notified their intention of meeting the wishes of the Indian Government by reducing the rate to India from 4s. 7d. to 4s. per word after the 1st July. The Eastern Extension Telegraph Company announced to the Conference that it would lower its rates to China and Australia, provided that other administrations concerned also reduced their charges; the exact amount of the reduction in both cases is not yet determined, but it will be either 2 francs or 2s. per word. There will also, after 1st July, 1886, be some modification in the rates to Cochin-China, Tonkin, and Japan.

The telephonic system of London is not one whit better than it was twelve months since, and we would commend to the careful consideration of all interested in the matter the following list showing the operations of the National Company and the prices charged to subscribers. We congratulate the National Company on its enterprise, but imagine there still remains much room for development and improvement. The statistics given are correct up to the 31st day of October, 1885:—

Name of Centre.	Annual Subscription.	No. of Lines.		Name of Centre.	Annual Subscription.	No. of Lines.

Total Centres = 34. Total Exchange Lines = 5,649. Total Private Lines = 995

The Company's trunk lines exist between the following towns:—

Dundee	and	Perth	Bradford	and	Halifax
Dundee	and	Forfar	Bradford	and	Dewsbury
Dundee	and	Arbroath	Leeds	and	Dewsbury
Edinburgh	and	Glasgow	Leeds	and	Huddersfield
Glasgow	and	Greenock	Leeds	and	Wakefield
Glasgow	and	Paisley	Dewsbury	and	Huddersfield
Glasgow	and	Dumbarton	Halifax	and	Huddersfield
Glasgow	and	Coatbridge	Birmingham	and	Wolverhampton
Glasgow	and	Hamilton	Birmingham	and	Wednesbury
Maryport	and	Workington	Wolverhampton	and	Wednesbury
Maryport	and	Whitehaven	Nottingham	and	Loughboro'
Bradford	and	Leeds	Sheffield	to	Leeds
Bradford	and	Huddersfield			Total number trunk lines = 25.

Passing from the general to the special, we may notice that during the year the second electrical railway has been opened. This railway is at Blackpool, and has been constructed upon the plans of Mr. Holroyd Smith. The time during which it has been in work is too short to give any real proof as to whether it will be a successful venture or not, and we must repeat, in season and out of season, that tramways or railways are not built for philanthropic purposes, or to prove scientific theories, but to pay the shareholders. The enterprise at Blackpool will be watched with a great deal of interest, and it is to be hoped the annual balance-sheet will be framed to give information, and not to hide from the general public the real state of affairs. If success attends this venture, other sea-side towns will follow the good example.

The electric railway at Brighton—the first of the kind in England—has to be looked upon in a somewhat different manner. It was initiated and has been carried out principally by the enterprise and energy of one man—Mr. Volk. This railway has been running throughout the whole year, and we have often referred to it in our columns.

There is not much to add to our previous remarks upon this most successful venture, except to say that it has continued running throughout the year, and carried a heavy traffic without hitch or delay. The motors in the cars have required no repairs beyond truing up the commutators occasionally; the generating dynamos have each required to be fitted with a new commutator. The severe work to which the plant is subjected proves that electric locomotion can be thoroughly depended upon to carry a heavy traffic, the cars here running incessantly for a period of twelve hours per day, and having a recorded mileage of 31,200 miles per annum.

The cost of traction is (using a gas engine) a fraction over 2d. per car mile, and the average earnings 1s. 3d. per mile. Of course the tramway has been constructed and carried out under exceptional circumstances, but the authorities of Brighton are to be highly praised for the spirited manner in which they have supported the enterprise, and enabled their townsman to show what really can be done in this direction.

On electric light work our space permits us to touch but very briefly in this issue, and therefore we take the work of the oldest firm, that of Siemens Brothers and Co., to start with:—

During the past year the various works carried out by this firm have in general been of the usual kind. In the electric light department, at the Inventories, the contract for the illumination of the grounds was given to Messrs. Siemens Brothers and Co., for which nearly 10,000 incandescent lamps were required. These were divided into twenty-three circuits, each of eight parallels of lamps, the twenty-three circuits being coupled up so as to form eight sections, the whole being controlled from a central switch room under the clock. For supplying the current required to work these lamps, three

Digitized by Google

Siemens self-regulating dynamos were provided, of the largest size ever made of that construction. These dynamos were of such power that two of them were capable of producing even more than the necessary current, the third being spare. During the whole of the time this installation (which may be considered as the most extensive of its kind yet carried out) was in work there was not the slightest hitch or breakdown in any of the electrical plant or apparatus, and we believe the result gave universal satisfaction to the large numbers of the public who visited the Exhibition. Contracts have been carried out to completely fit with electric light the following men-of-war for the Admiralty: — The "Imperieuse," "Collingwood," "Edinburgh," "Warspite," and "Rodney," and search lights for a large number of other ships and gunboats have also been supplied to order of the Government. A number of ships of the principal passenger lines of steamers have been fitted with the electric light. In cable work, Messrs. Siemens have completed the system of cables for the Mackay-Bennett Company, commenced in 1884 by the laying of a section from Waterville, in Ireland, to Havre, in France, and another from Waterville to Weston-super-Mare, near Bristol, this being the nearest point to London to which any Atlantic cable has, as yet, been brought; while on the other side of the Atlantic the cable is carried direct into the offices of the company, in the City of New York, without any intermediate land line. The Mackay-Bennett cables, therefore, now form a system consisting of two main cables from Waterville to America (one landing at Rockport, in Massachusetts, and the other at the office in New York), and branch cables from Waterville, one to Havre and the other to Weston-super-Mare. In addition to this work various repairs of cables have been carried out in the Atlantic, and we may mention the interesting fact that five repairs, all of them in deep water, from 2,000 to 2,600 fathoms, have been effected with the ss. "Faraday" within a period of twelve months, in addition to the work of laying those cables to which we have referred above.

Writing this portion of our notice for 1885 on its closing evening, we have great pleasure in wishing our subscribers and friends a Happy and Prosperous New Year for 1886.

CORRESPONDENCE.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The question raised by the narrative of the electric boy may be of much importance. If, as seems capable of demonstration, all the muscles of the human body depend upon the healthy existence of a permanent electric current, and each pair of muscles may be exerted without interference with the current operating among other muscles, we have much to learn which the existence of a so-called electric boy might enable us to elucidate. Some time time ago I saw some experiments in this direction conducted by Prof. Dewar. He not only showed, by means of a galvanometer, that when he exerted the muscle of one arm the needle deflected to the right, and when the corresponding muscle of the other arm was exerted it deflected to the left, but so delicate a pair of muscles as regulated the sight of each eye was shown with equal clearness to be similarly dependent upon a permanent electric current. This he did by surrounding the eye with a simple solution, and connecting it with the galvanometer, which immediately indicated the movement of the muscles, directing the sight to the right or left by the deflection of the needle in contrary directions. The effect of the displacement of the current by one set of muscles in no way affected the current associated with any other muscles, and although I am not at present aware of any way in which electrical research could be directed to prove the fact, I have no doubt so delicate a point as the interdependence between accommodation and convergence in vision would depend upon separate sets of muscles having separate permanent electric currents. Other interesting questions to be solved are:—The possibility of certain permanent currents existing in the human body being united without endangering life. The total strength of the permanent currents operating the human body. The possibility of determining the relative difference of strength, if any, in health and disease, in youth and age. The source of the periodical removal of the currents; if in the brain and sleep, by what special nerves or otherwise is the renewal supplied? Inquiries of this nature being assisted by the intelligence of the subject of the inquiry might lead to some comprehension of the mystery of the currents in the earth. The general utilisation of electricity would probably be much advanced by the success of such inquiries.—Yours, &c.,

RICHARD HERRING.

27, St. Mary's-road, Canonbury, 28th Dec., 1885.

NITRATE IN BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I shall be greatly obliged if you can give me any information on the following:—

1. Taking nitrate of soda, what are the correct proportions of water and sulphuric acid for depolarising solution?

2. Should the water be saturated with the nitrate before the sulphuric is added?

3. Given a saturated solution of nitrate of soda, is it capable of dissolving and holding in solution a further quantity of nitrate of potash and bichromate of potash, and if so would it necessitate an extra quantity of sulphuric acid?—Yours, &c.,

ATOM.

BICHROMATE OF POTASH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Can you inform me through *The Electrician* of a firm which manufactures bichromate of potash, and also of a firm from whom I can obtain, wholesale, rolled zinc rods ¾in. diameter and two or three yards long, for batteries?

I have a bichromate battery for lighting up my house, in which I use old carbons which have been used in Siemens and Brush arc lamps. The battery works well; but do you think it would work any better with proper battery carbons?

I am using incandescent lamps for fifteen volts and five volts; for the former I have for the main wires No. 14 and from the main to the lamps No. 22. For the latter I have No. 18 for main, and No. 24 from main to lamps. Am I using the proper numbers of wires? If you can give me the above information I shall be obliged.—Yours, &c.,

F. ISSELS.

THE WINDING OF VOLTMETERS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

I. The use of voltmeters for measuring the potential difference existing between the mains in electric light circuits, and for enabling us to maintain this potential difference constant, is so wide in its possible application, that it is unnecessary to dwell on the importance of voltmeters giving accurate indications. Indeed, the sensibility of an incandescent lamp to changes in the potential difference at its terminals is so great (the light, as we have shown in a previous communication to this society,† being in many cases proportional to the cube of the potential difference minus a constant) that it is necessary that voltmeters should record with great accuracy the potential difference, as well as quickly indicate any changes that may from time to time take place in this potential difference.

* Paper read before the Physical Society.

† The most economical potential difference to employ with incandescent lamps.—*Proc.* Phy. Soc., Vol. VII., page 40.

Digitized by Google

It is, therefore, desirable to consider what are the most important errors in commercial voltmeters as at present constructed, and how these errors may be practically diminished or altogether removed. They are :—

1. An error arising from the sensibility of the voltmeter varying with its resistance, and therefore with its temperature. This change of temperature is due partly to the variation of the temperature of the room and partly to the coils of the instrument becoming heated by the passage of the current through them.

2. An error arising from the sensibility of the instrument being temporarily varied by external magnetic disturbance.

3. An error arising from certain types of voltmeters altering in sensibility, so that their constants vary from time to time.

4. An error arising from the volt standards employed by different makers of voltmeters differing several per cent. from one another.

The variation in the resistance of a voltmeter produced by changes of temperature of the room can, of course, be made very small by winding the instrument with German silver wire, or better with platinum silver, or best of all with wire made of platinoid, or it may be made absolutely nought by using an outside resistance of carbon; or, lastly, if the voltmeter be simply wound with copper wire, this error, although large, can be accurately allowed for if the temperature of the voltmeter be known. But the error arising from the heating of the voltmeter by the passage of the current through it is much more difficult to allow for, as this rise of temperature of the instrument will be unknown. Hence it is important to reduce this error to a minimum, and it does not at all follow that the employment of German silver wire or even platinoid wire will affect this result; indeed, we have already given, in a previous communication made to this society*, general reasons showing that German silver is undesirable to be used in the winding of voltmeters. When, however, the diameter of the coil of the instrument exceeds a certain limit it would appear that German silver wire might be better for the outer coils, hence the following investigation has been made for the purpose of ascertaining whether in an instrument of the size of our solenoid or long range voltmeter any portion of the coil should be wound with German silver wire, and if so, how large a portion; also what should be the law of variation of sectional area of the wire with the diameter of the convolution in which it is wound, so that the heating error produced by the passage of the current through the voltmeter shall be a minimum.

Although the dimensions of the instrument adopted in the following investigation are those of this special form of voltmeter, the mode of considering the problem will apply equally well to any other galvanometer used as a voltmeter, or to the fine wire coil of an ohm-meter, power-meter, and erg-meter, or, indeed, in any case where it is desired to produce a given magnetic effect with a minimum error due to heating. It is only necessary to consider the case of a cylindrical coil of internal radius r_0 and external r_1 and length l, as it is easy to extend our reasoning to a coil of any other shape and dimensions.

II. At a place in the coil at a distance, r, from the axis let the cross section of the wire be x, let ρ be the specific resistance of the material, and γ the rate at which ρ increases with temperature, x, ρ, and γ being functions of r. For simplicity of calculation we shall neglect the volume of the insulating material. Let one spire of radius r produce a magnetic effect of the amount

$$K\,C\,r^d \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

C being the current, and d having in almost all instruments a value which lies between the limits -1 and 0. Also let

$$x = x_0\, r^a \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\rho = \rho_0\, r^b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$\rho\,\gamma = \rho_0\,\gamma_0\, r^c \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

In a layer of wire of thickness δr there are $\frac{l\,\delta r}{x}$ spires of wire, and the resistance of the layer is

$$\frac{2\pi r \rho l}{x^2}\delta r, \text{ or } \frac{2\pi r \rho_0 r^b l}{x_0^2 r^{2a}}\delta r, \text{ or } \frac{2\pi \rho_0 l r^{1+b-2a}}{x_0^2}\delta r,$$

so that the whole resistance of the coil is evidently

$$R = \frac{2\pi\rho_0 l}{m x_0^2}(r_1^m - r_0^m) \text{ if } m = 2 + b - 2a \quad . \quad . \quad . \quad . \quad (5)$$

The magnetic effect of the spires in the thickness δr is

$$K\,C\,r^d\, l\frac{\delta r}{x}, \text{ or } \frac{K\,C\,l}{x_0} r^{d-a}\,\delta r,$$

so that the whole magnetic effect of the coil is

$$M = \frac{K\,C\,l}{x_0 n}(r_1^n - r_0^n) \text{ if } n = d - a + 1 \quad . \quad . \quad . \quad . \quad (6)$$

We shall now assume that we can, by introducing thin strips of copper among the windings, give the same ease of cooling to unit volume of the wire everywhere; that is, after the current has flowed for some time, that the increase of temperature at any point is proportional to the rate at which current heat is produced per unit volume. Now,

$$C^2\frac{2\pi\rho_0}{x_0^2} r^{1+b-2a}\, l\,\delta r, \text{ or } C^2\frac{\rho_0}{x_0^2} r^{b-2a} \,.\, 2\pi r l \,\delta r$$

is the rate at which heat is produced in a layer of thickness δr.

This rate is $\frac{\rho_0}{x_0^2} r^{b-2a}$ times the volume of the layer. Therefore, the rate at which heat is produced *per unit volume* is $C^2\frac{\rho_0}{x_0^2} r^{b-2a}$; hence, by hypothesis, the increase of temperature is proportional to $C^2\frac{\rho_0}{x_0^2} r^{b-2a}$.

The increase of resistance of this layer is the resistance of the layer multiplied by γ times the increase of temperature, and is therefore proportional to

$$\frac{2\pi\rho_0}{x_0^2}\, l\, r^{1+b-2a}\,\delta r \,.\, \gamma \,.\, \frac{C^2\rho_0}{x_0^2} r^{b-2a},$$

$$\text{or to } \gamma\frac{C^2\rho_0^2}{x_0^4} r^{1+2b-4a} \text{ where } \gamma = \gamma_0 r^{c-b},$$

and the whole increase of resistance is proportional to

$$\int_{r_0}^{r_1} \gamma_0 C^2 \frac{\rho_0^2}{x_0^4} r^{1+b+c-4a}\, d r,$$

$$\text{or } \gamma_0 C^2 \frac{\rho_0^2}{p\, x_0^4}(r_1^p - r_0^p), \text{ if } p = 2 + b - 4a + c. \quad . \quad (7)$$

so that the fractional change of resistance is proportional to

$$\frac{\gamma_0 C^2 \rho_0^2}{R\, x_0^4\, p}(r_1^p - r_0^p) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

Now, regarding M as constant, and substituting for C and R from (6) (5) and (8), we observe that the fractional change of resistance due to heating is proportional to

$$\gamma_0\rho_0 \cdot \frac{n^2}{(r_1^n - r_0^n)^2} \cdot \frac{m}{r_1^m - r_0^m} \cdot \frac{r_1^p - r_0^p}{p} \quad . \quad . \quad (9)$$

and it is required to find the values of a, b, and c, for which this expression is a minimum.

III. It may be seen that the error (9) is less as $\gamma_0\,\rho_0$ becomes less, therefore $\gamma_0\,\rho_0$ should be made as small as possible so that *when wires of two metals, as for example copper and German silver, are employed, the wire for which $\gamma\,\rho$ has the least value, that is the copper, should be used for the inner winding.* It is, however, when we consider the waste of electric energy in the coil that the great objection to the use of German silver for the internal winding becomes still more striking, for the rate of production of heat in the coil is proportional to $C^2 R$ which, from (6) and (5), equals

$$\frac{x_0^2 n^2 M^2}{K^2 l^2 (r_1^n - r_0^n)} \times \frac{2\pi\rho_0 l}{m\, x_0^2}(r_1^m - r_0^m).$$

* "Direct Reading Electro-Measuring Instruments, and a Non-Sparking Key."—*Proc.* Phy. Soc., Vol. VI., page 69.

Digitized by Google

Hence to produce the same magnetic effect M in a coil of given length l, the rate of production of heat is proportional to

$$\frac{n^2}{(r_1^n - r_0^n)^2} \times \frac{r_1^m - r_0^m}{m} \rho_0 \quad . \quad . \quad . \quad (10)$$

Consequently the rate of wasting electrical energy in heat will be thirteen times as great if German silver wire be used as it will be if copper is used, when a given angular deflection is produced, no matter what be the gauge of wire employed—that is, whether the voltmeter be wound to measure a maximum potential difference of 50 or of 500 volts.

Eliminating r from (3) and (4) it follows that

$$\left(\frac{\gamma \rho}{\gamma_0 \rho_0}\right)^{\frac{1}{c}} = \left(\frac{\rho}{\rho_0}\right)^{\frac{1}{b}} \quad . \quad . \quad . \quad . \quad (11)$$

where b may have any arbitrary value. Hence, if there is a regular change possible in the value of $\gamma \rho$, such as is given in (4), we must have

$$c = \mathrm{P} b$$

where P is some constant. Equation (11) therefore becomes

$$\frac{\gamma \rho}{\gamma_0 \rho_0} = \left(\frac{\rho}{\rho_0}\right)^{\mathrm{P}} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

If, therefore, our wire in the inside of the coil is of copper, and at the outside of German silver,

$$\gamma \rho = \frac{13}{9} \gamma_0 \rho_0,$$

or

$$\rho = 13 \rho_0.$$

Hence from (11) $\frac{13}{9} = 13^{\mathrm{P}}$,

or $\mathrm{P} = 0{\cdot}143$,

and $c = 0{\cdot}143 b \quad . \quad . \quad . \quad . \quad . \quad . \quad (13)$

It is certain that generally the relationship between γ and ρ cannot be of the simple character here assumed, but inasmuch as our results are only applied in cases where the windings are either of German silver or of copper, or of the two together—and in these cases the expressions used are quite correct—there is no practical objection to the use of such a law. The law is very nearly the same as the assumption that a wire of any material lying electrically between German silver and copper is made up of wires of German silver and copper.

Since from (7) $p = 2 + b - 4a + c$,

it follows, using (13), that $p = 2 + 1{\cdot}143 b - 4a \quad . \quad . \quad . \quad (14)$

and the values of m and n are given respectively in terms of a, b, and d in (5) and (6), and are

$$m = 2 + b - 2a \quad . \quad . \quad . \quad . \quad . \quad (14)$$

$$n = d - a + 1 \quad . \quad . \quad . \quad . \quad . \quad . \quad (14)$$

In our solenoid voltmeter r_0 equals 1, r_1 equals 8, and d equals − 1, and since the greatest value of ρ is $13\rho_0$, it follows that r^b cannot be greater than 13; but b is a constant, and the greatest value of r is 8, therefore b must be less than 2. From (14), since b is always small, we see after a has reached a certain large value that p, m, and n increase numerically as a increases, and are positive when a is negative, and *vice versâ*, also that, finally, p equals $2m$, or equals $4n$.

Substituting the values for r_0 and r_1 the error (9) may be written

$$\frac{\gamma_0 \rho_0 \left(\frac{n}{8^n - 1}\right)^2 \left(\frac{m}{8^m - 1}\right)}{\frac{p}{8^p - 1}}$$

and it may be seen by inspection that each of the factors of which it is composed is always positive, whether m, n, and p be positive or negative. Therefore the error is always positive. For large values of m, n, and p the error may be written

$$\frac{\left(\frac{n}{8^n - 1}\right)\left(\frac{2^n}{8^{2n} - 1}\right)}{\frac{4^n}{8^{4n} - 1}} \text{ which equals } \frac{\left(\frac{n}{8^n - 1}\right)^2}{\frac{2}{8^{2n} + 1}}, \text{ or } \frac{n^2 (8^{2n} + 1)}{8^{2n} + 1 - 2 \times 8^n}$$

This expression is always greater than n^2, whether n be positive or negative, and is therefore very great, since n is great. Consequently, for large positive or negative values of m, n, and p the error (9) becomes very great, and therefore it can have no maximum. The values of a and b, therefore, found from equating to nought its differential coefficients with respect to a and to b, will give a minimum value of this error. And the error will be a minimum when its logarithm is a minimum. Now, taking its logarithm, putting r_0 equal to 1, and r_1 equal to 8, differentiating with regard to a and b respectively, and equating to zero, we arrive at the equations

$$\phi(n) - 0{\cdot}857 \phi(p) = 0 \quad . \quad . \quad . \quad . \quad (15)$$

$$\phi(m) - 1{\cdot}143 \phi(p) = 0 \quad . \quad . \quad . \quad . \quad (16)$$

where $$\phi(a) = \frac{\log \epsilon^8}{1 - 8^{-a}} - \frac{1}{a} \quad (17)$$

To assist in the solution of these three simultaneous equations, we calculated the following table :—

Table I.

a	$\phi(a)$
− 3	0·3293
− 2	0·4670
− 1	0·7029
0	1·0397
1	1·3764
2	1·6124
3	1·7502
4·5	1·8474
10	1·9794
100	2·0694

and in order to solve these three equations we used the following artifice :—A curve was first plotted on squared paper with $\phi(a)$ as ordinate, and a as abscissa, and by means of this curve for any value of $\phi(a)$ given we could at once find a approximately.

Table II. was then arrived at in the following way :—A value of p was chosen, and $\phi(p)$ written down. Then, since $0{\cdot}857 \phi(p)$ is equal to $\phi(n)$ by (15), n was known from this by the curve for $\phi(a)$; m was next found in the same way from (16). Thus columns 1 and 4 in Table II. contain values of p and n which satisfy (15), and which were obtained in this way, while in columns 1 and 6 we have values of p and m which satisfy (16).

Table II.

p	$\phi(p)$	$0{\cdot}857 \phi(p)$ or $\phi(n)$	n	$1{\cdot}143 \phi(p)$ or $\phi(m)$	m
2	1·6124	1·381	1·03	1·842	4·35
1	1·3764	1·18	0·39	1·572	1·78
0	1·0397	0·8913	− 0·425	1·189	0·425
− 1	0·70295	0·6026	− 1·370	0·8035	− 0·69
− 2	0·467	0·4002	− 2·38	0·5337	− 1·69

Now, first using the pair of columns 1 and 4, we chose corresponding values of p and n, say 2 and 1·03; then, since

from (14) $2 = 2 + 1{\cdot}143 b - 4a$,

and $1{\cdot}03 = d - a + 1$

we could calculate a pair of values for a and b which satisfied (14) and (15), since d was assumed to be known. Next, taking another pair of values of p and n from Table II., another pair of values of a and b was calculated, and so on.

Plotting these values of a and b as co-ordinates of points on squared paper we obtained the curve *sss* (Fig. 1)* the co-ordinates of every point of which are the values of a and b that satisfy (15). In the same way we drew the curve *ttt* for (16), and the co-ordinates of the point of intersection Z are the values of a and b which satisfy (15) and (16), and therefore make the error (9) a minimum.

Thus, for example, taking $d = -1$, as seems to be the case

* This and the two succeeding figures are only about one-twelfth of the size each way of the figures actually employed in the calculations.

Digitized by Google

in our solenoid instrument, we find that, with some approximation to accuracy,

$$a = 0{\cdot}19 \quad \text{and} \quad b = -0{\cdot}82$$

for minimum error. But if we have used our material of least resistance for the inner winding, b cannot in practice be less than 0, for ρ cannot be less than ρ_0; and since r is never

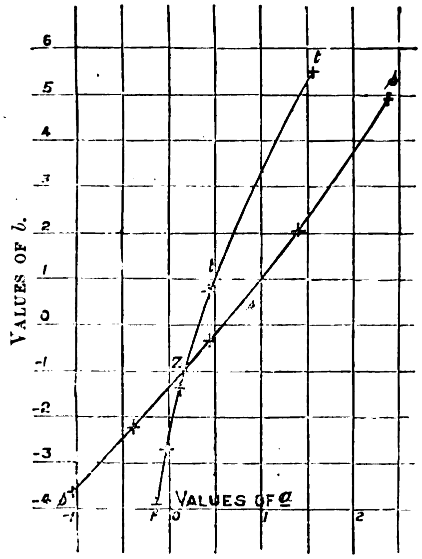

Fig. 1.

less than 1, ρ would be some fraction of ρ_0 if b were less than 0. Hence, in practice we find that b must equal 0—that is, *a less heating error is produced when all the wire is of copper than when we use German silver windings on the outside of the coil.*

(To be continued.)

DYNAMO TESTS.

It is well known to our readers that a series of dynamo tests were carried out at the Philadelphia Exhibition. The full report of these tests has just been issued by the Franklin Institute. All tests have a certain value, and although much has been said against the tests at the Philadelphia Exhibition, we do not hesitate to give the report almost verbatim, so that our readers can judge for themselves the exact value to be given to the figures. The sections preceding the commencement of our reprint are of no interest scientifically, and as our space is none too great, we have not given them.

Section III.—*Preliminary Tests.*

5. The resistance of the field magnet coils and of the armature coils will be measured as follows :—A strong current from a secondary battery shall be passed through these coils and amperemeter and sensitive voltameter used to determine current and fall of potential. The resistance will be determined from these measurements. As an additional precaution, a strip of German silver of known resistance shall have its fall of potential measured with the same current and instruments. These measurements shall be made before and after the tests, with the machine hot and cold.

Insulation Resistance.

6. Tests will be made of the insulation of the terminals of the machine from its metal bed plate. Tests will be made of the insulation resistance between the commutator and the axle.

7. It is understood between the parties that if any mechanical defect is observed, another machine may be substituted if the committee agree that such defect exists. The competitors shall have reasonable opportunity to obtain information of the progress of the tests, and to know the figures of each test for the object of ascertaining errors in time for correction. The observations made will be publicly posted before the machine is removed from the dynamometer.

Calibration of Instruments.

8. The constants of all instruments used shall be determined by at least two independent methods. The companies shall have opportunity to inspect and observe the methods used, and shall be furnished with the constants of the instruments immediately after they have been determined. All objections to the methods used will be received and acted upon as provided under Section IV., Article 17.

Section IV.

Quantitative Tests.

9. The dynamo to be tested will be run under full load for ten hours continuously, to see that all is in good working order before the tests begin.

10. For the actual test the machine shall be run and the temperatures of the pole pieces and armatures observed until a uniform temperature is reached.

11. When a uniform temperature for each load is reached, the measurements of power shall begin.

12. The machine will be tested on both live and dead resistances.

13. The machine will be tested on one-quarter, one-half, three-fourths, and full load. In the latter case, to be run at least five hours after a uniform temperature is reached.

14. Full measurements of friction and of energy expended in field will be made in each case.

Dynamometric Measurements.

15. The shaft of the dynamo will be directly attached to the end of the shaft of Tatham's dynamometer, by means of a universal joint coupling, and the horse-power used read from the dynamometer, unless the committee, for reason, shall decide otherwise.

Observations.

16. The observations on the dynamometer, current galvanometer, and potential galvanometer, and all other instruments, will be taken at synchronous intervals. The temperature of the room will be made as even as possible, and the temperature noted and necessary corrections made. The adjustment and oiling of machines shall be in the hands of the authorised expert for the company.

17. In case any objection be made, or difference of opinion should arise between the committee and the contestants, the unanimous vote of the committee shall be final. If, however, there be not a unanimous vote, the minority of the committee shall appoint one referee and the majority another; these two shall appoint a third referee. The decision of the majority of these referees shall be final.

In all determinations of efficiency of machines, measurement of potential shall be made (simultaneously with measurements of the current strength) at the binding posts of the machine, and at such other points of the circuit as will determine the total fall of potential, due to the resistance of the leads, connections and switches included in circuit with the instruments used for determining current strength. From these measurements, the loss shall be calculated and credited to the machine under trial.—(Signed) Francis R. Upton, United States Electric Lighting Company, per Edward Weston, electrician.

Fig. 1 gives the general arrangement of the apparatus. The test room, in which most of the instruments for electrical measurement were placed, was in about the middle of the exhibition building of the Franklin Institute. The dynamos, with the boiler and engine used in running them, were in a shed at one corner of the building; and the resistances for their external circuit—lamps and German silver strips—in a room inside the building and very near the shed.

The storage battery, tangent galvanometer for current calibrations, and galvanometer for measuring field currents, were in different parts of the building, far enough from the test room not to affect the instruments in it. The leads from the dynamos and storage battery and to the tangent galvanometer were of heavy, insulated copper cable. They were taken to the corner of the test house farthest from the instruments, and where they approached it the two parts of a circuit were

Digitized by Google

twisted together, one of them being covered with rubber tubing as an additional precaution against leakage. Even with the heaviest currents (about 400 amperes) there was no effect on the instruments, and calibrations made both when the dynamos were and were not running, showed that any disturbance from currents in the leads had been avoided. Before any measurements were made, the insulation resistances between the leads themselves, and from the leads to the ground, were carefully tested and found in every case to be over fifty megohms; and measurements at intervals during the tests showed that they remained about the same.

Observations.

The power applied to the dynamos was measured by a Tatham dynamometer, while the electrical energy was calculated from observations of the potential at the terminals of the machine, the currents in the external circuit and field, and the resistance of the armature. The latter was measured by sending a current from a storage battery through the armature and observing the current in the circuit and fall of potential between the terminals of the machine. The dynamos were run both on lamps and dead resistance, the value of the latter serving as a rough check on the potential and current.

APPARATUS.

Storage Battery.—This was kindly furnished by Mr. Weston, and was used for all calibrations, measurements of armature resistance, &c. Seventeen cells in series were generally employed; they were placed on boards separated from the floor by porcelain insulators.

Tangent Galvanometer—This was used for calibrating the current galvanometer. It consisted of a single turn of a large-sized wire fastened on the edge of a wooden disc which was nailed against a square board frame. The ends of the wire were bent up parallel to each other and fastened by brass connectors to the leads. A correction due to the space between the ends of the turn was applied to the mean radius. The diameter, about two metres, was measured in different directions, and the mean taken in calculating the constant. There was a space cut in the middle of the wooden frame, with a shelf for the compass and needle. After the needle was adjusted to the centre and levelled, plumb lines and pointers were arranged so that any warping or change of level could be at once detected. The value of H was determined by a magnetometer of the coast survey pattern with detached theodolite, it was found to be ·1938, and the constant of the galvanometer 31·088 amperes.

External Resistances of Dynamos.—The "dead" resistances for the external circuit of the dynamos were made of German silver strips 1¼in. wide by about ·01in. thick. They were eight in number, each wound on a frame about 3ft. square by 10ft. high, made of four wooden uprights with pieces framed across at the top and bottom. Porcelain insulators were fastened horizontally to the cross pieces and the resistances passed under one of the bottom insulators, over one at the top, to the bottom again, &c. Heavy copper wires were hard soldered to the ends of the strips and taken to the switch-board. The resistances were adjusted by cutting out part of the strip by a short length of German silver with clamps at the ends, which could be shifted to cut out as many of the turns as was desired. The coils were adjusted by means of a calibrated bridge, to 2·400 ohms at 20° C. There was a good air circulation in the room, and fifty amperes could be carried by each coil. In the same room with the German silver resistances were the racks for the incandescent lamps used for "live" resistances.

Switch-board.—Two troughs about 2½ft. long and 1½in. wide, and 10in. apart, were cut in a heavy block of wood. Between them were bored two rows of eight holes each, and into these were fitted glass insulators turned upside down to serve as mercury cups. The wood was soaked in boiling paraffin, and melted paraffin poured between the cups and allowed to harden. The distance between the troughs and the middle of the nearest row of cups was three and a half inches; between the two rows, and the cups in each row, three inches. The cups and troughs were filled with mercury, heavy amalgamated copper rods in the latter serving to increase the conductivity. The resistances were brought to opposite cups in the two rows. The dynamo circuit was from one terminal of the machine to an ordinary Edison switch, by which the current could be made or broken, to one of the troughs, through the resistance to the other trough, to the test house, passing through the fixed resistance for current measurement there, back by the other lead to the dynamo. Connections at the switchboard were made by thick U-shaped copper rods, with a stretch of three and one half inches. The resistances could be readily arranged in any desired way, with little or no chance of causing accident by making mistakes. The insulation between the troughs and the cups and the troughs themselves was practically perfect.

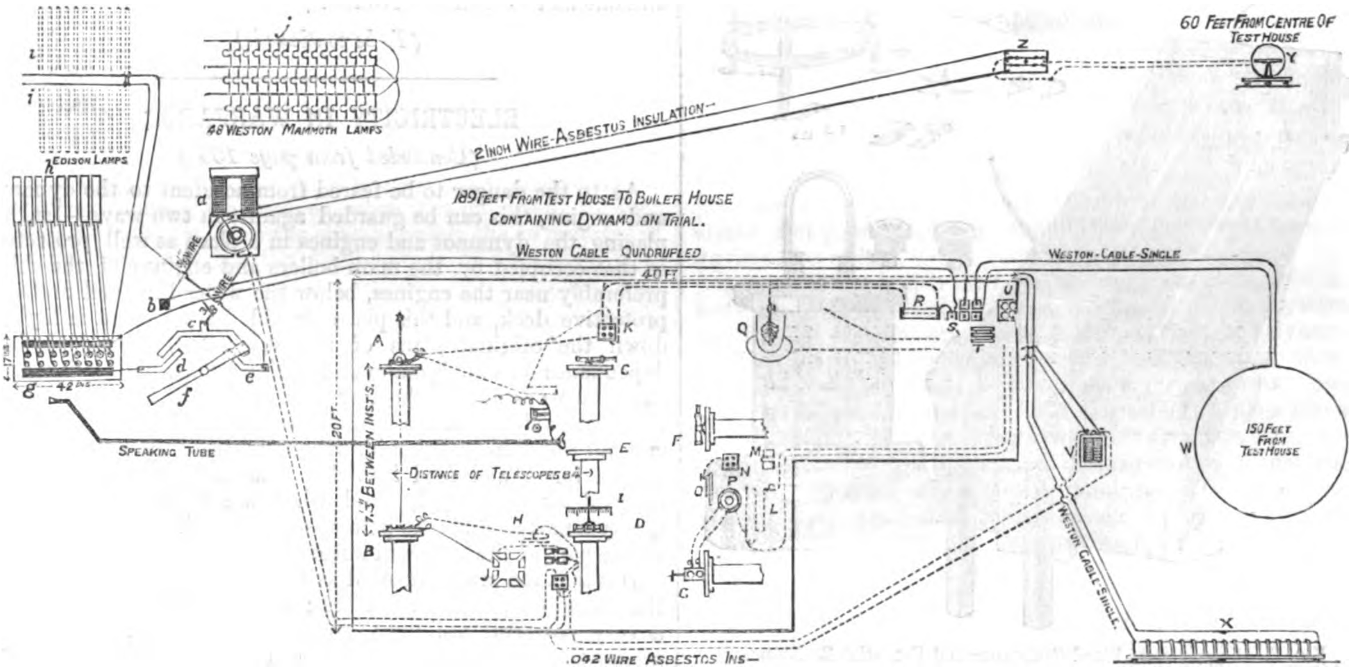

Fig. 1.—Arrangement of the Apparatus in the Test Room.

Digitized by Google

Field Galvanometer.—The current in the field of the dynamos was measured by a tangent galvanometer of the Helmholtz type, the coils being each a single turn of large-sized wire. It was calibrated at the same time as the current galvanometer, being reversed as often as possible, and the same end of the needle read on each side of the zero mark.

Wheatstone Bridge.—For measuring resistances that could not be taken to the Johns Hopkins University, a resistance box, with a bridge attachment by Elliott, of London, was used, with a Thomson astatic mirror galvanometer. The box was standardised, as described below.

Calorimeter.—The calorimeter is shown below in Fig. 2. This was used for calibrating both the potential and current galvanometers; it was made of copper, was cylindrical in shape, about 8in. in diameter by 10in. in height, and held about eighteen pounds of water. The cover was screwed to a flange on the cylinder, the joint being water-tight; in it were holes with raised flanges around them, for the terminals of the coil and the thermometer. For stirring, a shaft, working in a bearing on the bottom of the cylinder and passing through the cover, had on it five paddles

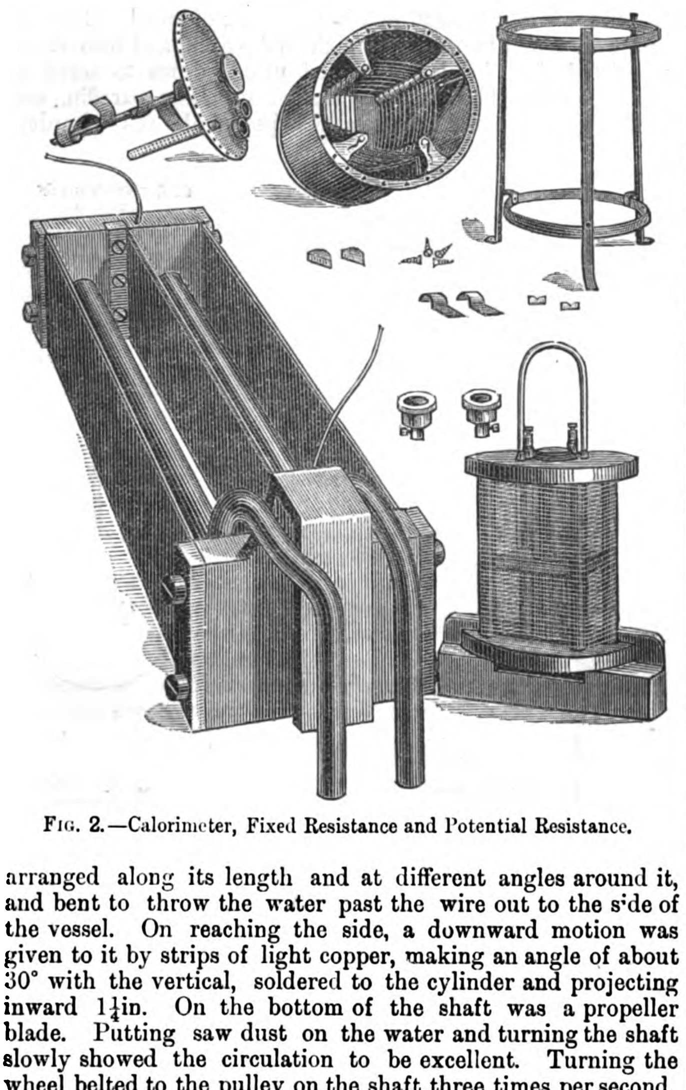

Fig. 2.—Calorimeter, Fixed Resistance and Potential Resistance.

arranged along its length and at different angles around it, and bent to throw the water past the wire out to the side of the vessel. On reaching the side, a downward motion was given to it by strips of light copper, making an angle of about 30° with the vertical, soldered to the cylinder and projecting inward $1\frac{1}{4}$in. On the bottom of the shaft was a propeller blade. Putting saw dust on the water and turning the shaft slowly showed the circulation to be excellent. Turning the wheel belted to the pulley on the shaft three times per second, raised the temperature of the calorimeter ·02° C. in five minutes. In the later experiments it was only turned once per second, so the error from this correction must have been small. In the first three experiments, copper wire of about 1·3 ohms resistance was used; in the last two platinum-silver wire of 1·1 ohms. The coil was held in the cylinder as follows:—At equal distances around the cylinder, at the top and bottom, were soldered pieces of copper projecting inward, with clamps at their ends. The wire was wound on glass rods held in a light framework; the whole was placed in the cylinder, the rods clamped in place and the framework cut away, leaving a clear space for the stirring arrangement. The terminals were small copper cups, thoroughly amalgamated and partly filled with mercury. They were surrounded by a rim of ebonite and wedged in their places in the cover. The calorimeter fitted in a light iron frame, from which it was separated by small blocks of ebonite. The whole was surrounded by a tin cylinder fitting closely on the shelf to which the frame was fastened, so there was no draught past the cylinder.

Balances.—Two balances were used, one for weighing the calorimeter, the other in voltameter work. The former could weigh up to thirty pounds and was very sensitive. The latter was an excellent analytical balance. Both were by Trœmner, of Philadelphia, and the weights were compared with standards in his possession.

Thermometers.—The thermometers generally used were by Green, of New York. They were divided into degrees and tenths, and were compared at the Johns Hopkins University with one of the standards there, the apparatus used in the comparison being that described by Prof. Rowland, in his "Determination of the Mechanical Equivalent of Heat."* For the last two calorimeter experiments, a thermometer by Hicks, of London, was used. It was graduated to centimetres and millimetres, and was one of those used by Mr. Leibig, in his work "On the Variation of the Specific Heat of Water."†

Potential and Current Galvanometers.—These will be described under measurements of potential and current. They, with the other instruments in the test house, rested on stone slabs, cemented on the top of heavy wooden posts, sunk about two and one-half feet in the ground.

(To be continued.)

ELECTRICITY IN WARFARE.‡

(Concluded from page 135.)

As to the danger to be feared from accident to the dynamo and engine, this can be guarded against in two ways—1st, by placing the dynamos and engines in a place as well protected as that occupied by the main boilers and engines of the ship, preferably near the engines, below the water line, and under a protective deck, and this place should be provided in laying down the original plans of the ship; 2nd, by not placing dependence on one dynamo and engine alone, but by dividing the total work among three or four, so that in case of accident to one the ship will have the benefit of all the others. To this end, all the dynamos should, of course, be of the same electromotive force, and feed into the same mains, from which all lamps draw their supply, and which are fed by feeders from the dynamos at different points, so that accident to the mains at one part of the ship will affect that part only.

But it is the arc light, used as what is called a search light, that is most valuable in warfare; a search light being simply a very powerful arc light, so arranged with a catadioptric mirror that it throws out a very concentrated beam of light, and so mounted that this light can be cast in any desired direction, and made to illuminate any locality which it is desired to inspect. I believe the first use made of search lights was in the siege of Paris in the Franco-Prussian war, when the French employed them to discover the operations of the besieging army at night. Their value, from a military point of view, was so evident that other nations took the hint and introduced them into their military and naval services. Since then their use has been extending, more probably for ship use than for use on shore, though they are also employed considerably in forts guarding the approach to harbours, to watch for the approach of hostile fleets, torpedo boats, or countermining expeditions at night.

For the use of an army in the field search lights are mounted on suitable waggons, together with portable boilers and engines, so that they can be taken on the march, moved to any part of the field, the top of a hill for instance, and

Digitized by Google

employed at night whenever desired. It is clear that a search light might often be very useful in doing such work as searching for wounded after a battle, examining the nature of the ground in a comparatively unknown country, watching the enemy when a surprise might be anticipated, guarding against a sortie from a beleagured fort or city, &c., on many occasions, in fact, when the darkness of the night might be a hindrance to the operations of an army or an element of insecurity. On board men-of-war the principal use of the search light has been in watching for the attack of torpedo boats; but the experiments in Bantry Bay last July showed that it was often useful in detecting the approach of hostile ships, in aiding the sighting of guns at night by bringing the target out clearly, and in embarassing the operations of a torpedo boat or ship in trying to force a passage up a channel, by dazzling the eyes of the enemy one instant and leaving them in total darkness the next. It was related that in Africa some three years ago an attack on a fort was frustrated by a single search light. The barbarians advanced to the assault brave and determined, under cover of darkness, but were suddenly terrified by finding themselves enveloped in an awful and miraculous light which turned night into day. Halting for an instant, they covered their eyes to shield them from its dazzling whiteness, then suddenly turned and fled in panic. But even had they not been barbarians, even had they been trained soldiers of a highly civilised people, how bewildered they would have been to find themselves suddenly in such a brilliant light that their eyes were blinded so that they could not see to pick their way; and then, in a few seconds, just as the pupils of their eyes had contracted under the influence of the light, to find themselves suddenly in total darkness! Such alternations of dazzling light and black darkness would render the march of an attacking force over a broken country toward a fort a very difficult undertaking, for it should not be forgotten how dependent we are upon our eyes for our most simple actions, and how much our eyes assist us, even in the dark.

It may be pointed out here that the search light, like all other military instruments, must be used with judgment. It should not be used, for instance, when it is important to keep your position secret from the enemy, unless the advantages of observing him outweigh the disadvantage of disclosing your own position, or unless you can immediately extinguish your light, and change your position. In order to use the search light effectively on board ship, there should be four on each side of the ship. Search lamps are of much higher power than any other lamps that have ever been made, and the effect of the white cylinder of light, as it touches up the different points of the land or sea over which it is made to rapidly pass, is striking and beautiful in the extreme. The people of Philadelphia may remember the naval search light with which I used to illuminate the city last autumn, and do not have to be assured of its power and beauty. The best idea that I got of its illuminating effect was got one night when I went to the tower of the Pennsylvanian Railway depot, and watched the light stationed at the Electrical Exhibition building on Thirty-Second-street. The ray of light, when turned at right angles to my direction, looked like a silver arrow going through the sky, and when it was turned on me I could read the fine print of a railroad time-table at arms' length. For signalling at night, incandescent lights and search lights have both been used, the search lights being employed to reach long distances, or to reach points hidden by hills or other intervening objects. In using the search light in this case, the beam is thrown into the sky, and signals are made by showing long and short flashes, or by interrupting the beam in accordance with any preconcerted code. Flashes from the search light which I had at the Electrical Exhibition last autumn were seen from a distance of thirty miles. In using incandescent lamps for night signalling, the simplest way is to arrange a keyboard with keys marked with certain numbers, indicating the numbers of lamps arranged in a prominent position, which will burn while that key is being pressed. If it be desired to signal the number 5348, for instance, meaning, let us suppose, "Prepare to receive a torpedo attack," it is only necessary to press in succession keys marked 5, 3, 4, and 8, and the light of 5, 3, 4, and 8 lamps will successively blaze out and expire. Other codes, of course, can be used; the Morse code, for instance, in which a dash can be denoted by two lamps and a dot by one. One lamp could, of course, be used, the dot being denoted by a short flash and a dash by a long flash; but it is found best, practically, not to use time intervals in optical telegraphy.

Electric lights have been used considerably of late in photographing the bores of great guns. Views can be thus obtained of any part of the bore, showing whether the gun has been accurately bored and rifled, and showing how the metal is standing the erosion of the powder gases. One of the needs arising in modern warfare is means for handling heavy ordnance with speed and precision, and for bringing up ammunition. Guns, carriages, and ammunition have increased so much in weight, that it has become more difficult to handle them quickly than it used to be, and yet the speed of ships has so increased that there is more necessity for handling them quickly. The electric motor will certainly be used for handling ordnance on board ships not very heavily plated with armour, for it is clear that a small wire is a much more convenient way of conveying energy to a motor of any kind, and is much less liable to injury in action than a comparatively large pipe for conveying steam, compressed air, or water under pressure; and, besides, the electric motor is the ideal engine for work on board ship, by reason of its smooth and silent motion, its freedom from dirt and grease, the readiness with which it can be started, stopped and reversed, and its high efficiency. In forts, Colonel Hamilton, U.S.A., says that heavy guns must be worked by dynamo-electric machinery, since some other power than manual power must be employed, and since electricity is better than steam, compressed air, or water under pressure, because it can be conveyed from a central source by a single wire. Now, in forts, it is clear that the dynamos for search lights and incandescent lights, and for generating power for the electric motors for handling the guns, could be placed in a well-protected spot, and the wires leading therefrom could pass to the guns through underground pipes, where they would be well protected from projectiles, and the guns could be pointed in any desired direction with speed, silence and precision, by the simple turning of a lever or the moving of a switch.

It is probable that, in the near future, every man-of-war and every fort will be fitted with a complete "electrical system," well protected from projectiles, which will include dynamos capable of supplying a very large amount of electrical energy to a system of mains, from which all the incandescent lights, all the search lights, and all the motors of different sorts can draw the supply of energy requisite for their needs.

Electrical launches have been tried abroad to some extent, and with results which — though not completely satisfactory—give promise of success in the future. These boats are propelled in the same way as other boats—that is, by a propeller revolved by an engine—except that the engine is an electrical, instead of a steam engine. The electrical engine draws its power from what are called storage batteries carried in the boat. These storage batteries are first charged by a dynamo ashore or on board ship, and then are capable of rendering up to the motor the electrical energy stored in them, so that the motor is made to revolve, and thus cause the revolution of the propeller and the advance of the boat through the water. These electrical launches have carried hundreds of people, and have made a speed of about eight knots per hour, and the electric engine has worked perfectly well; but there has been considerable trouble with the storage batteries. Now, these storage batteries are improving every day, and as their defects do not seem irremediable, and as a great number of electricians are devoting study and experiment to them, we may hope that storage batteries will soon be efficient and durable. This done, the electric launch will certainly replace the steam launch in warfare, by reason of the quickness with which an electrical launch can be got ready, as there are no fires to be lighted, and, above all, by reason of the noiselessness of the electro-motor, and of the fact that in an electrical launch no flame ever flares up above the smoke pipe. With steam torpedo boats this flame frequently betrays them—that is, if the noise of the exhaust has not already done so. In using

Digitized by Google

electrical launches in warfare, two sets of storage batteries will, of course, be necessary, so that one set can be replaced by another, and used while the first set is being recharged.

A novel application of electricity has recently been made in what have been named "electric sights." It is well known that it is difficult to get a sight at an object in the dark—first, because the object itself cannot be distinctly seen, and, second, because the front sight of the gun cannot be distinctly seen. Now, Mr. Gaston Trouvé has recently invented an electric sight no larger than the ordinary front sight of a musket, which consists simply of a filament of fine wire in a glass tube, covered with metal on all sides save at the back. It looks much like an ordinary sight, except to a man looking along the barrel towards the back of the lamp, but a man so looking sees a fine, incandescent wire. The battery is said to be no larger than a man's finger, and to be attached to the barrel near the muzzle by simple rubber bands, so arranged that the act of attaching the battery to the barrel automatically makes connection with the sight, and so arranged, also, that the liquid of the battery is out of action except when the musket is brought into a horizontal position for firing. To throw a good light upon the target, the same inventor has devised a small electric lamp and projector, which is placed on the barrel near the muzzle by rubber bands, the battery being held at the belt of the marksman, with such connections that the act of pressing the butt of the musket against the shoulder completes the electric circuit, and causes a bright cylinder of light to fall on the target, thus bringing it out into strong relief, and enabling the marksman to get as good a shot as in the daytime. An application of electricity coming somewhat into use abroad in Continental armies is in connection with ballooning, which has received there the benefit of considerable attention and experiment. It is well known to all here that balloons have been much used for observing the movements of the enemy from a distance, and now it is reported that not only have balloons been successfully fitted with telephones, for communicating at once to people on the ground the nature of the information gathered, but also with small search lights, by which the ground can be illumined for a considerable distance at night, and the enemy's manœuvres discovered. Incandescent lamps have also been sent up in small translucent captive balloons, and under small ordinary captive balloons, and signals have been transmitted to a distance by making and breaking the current according to a preconcerted code.

Yet another way in which electricity will undoubtedly be used in any future war between civilised powers is in submarine boats, or boats which go beneath the surface of the water, to attack ships below the water line. Though it cannot be said that submarine boats have ever yet been successful, still, submarine boats are being improved, and men have always been found willing to risk their lives in them. Some have been devised of late years in which the propelling power is electricity derived from storage batteries.

In submarine diving the telephone has been used with success in maintaining constant communication between the diver and his attendants above water; and the incandescent lamp, suitably protected, has also been lowered into the water to light him at his work. Submarine diving will certainly play a part in future wars, the diver descending to cut an enemy's torpedo cables, or to inspect or repair damages to submarine mines or to ships. Progress is now beginning on what have been christened "electrical guns," in which the cartridge contains an electric fuze, which is ignited by pressing an electric push-button on the gun, instead of containing the ordinary percussion primer, which is struck by a hammer or bolt when the trigger is pulled. At present this invention has not reached the practical stage, and the necessity for a battery to fire the cartridge is decidedly an objection. Yet we should remember that the battery required is very small, that it needs very little care, and that it will last a long time. We should also note that an electric gun possessses the great advantage that a better aim can be got with it than with one fired by a trigger-hammer, for the reason that the hard pull of a trigger causes a movement of the barrel, except in the hands of the most highly-skilled marksman. Now, this hard pull of the trigger is a necessity, since the hammer or bolt must have considerable mass in order that it may be strong enough to strike the primer with sufficient force to explode it, and having considerable mass, it must have, necessarily, considerable inertia, so that it needs a deep notch in order to hold it firm at full cock when jarred, and this deep notch necessitates a strong pull on the trigger. But with an electric gun the circuit-closing parts can be very small and light, and can be put into a recess in the butt of the gun out of the way of chance blows, so that when it is desired to fire, a very light pressure of the finger is all that is needed, and yet from the small inertia of the parts a sudden shock will not cause accidental closing of the circuit and firing of the gun.

We have now taken a running survey of the uses of electricity in war, and we find that they include nearly all the uses to which electricity can be put. Warfare now means more than the mere handling and provisioning of troops and ships; it means, in addition, the intelligent employment of scientific instruments. Particularly is this the case with naval warfare, for a modern ship, considered as a whole, is, in itself, the most elaborate, complicated, and powerful machine existing. Science has made warfare a greater thing than scientists themselves foresaw, for it has put into the hands of our naval and military commanders weapons surpassing in power and length of reach the fabled weapons of mythology. Yet our wonder and admiration at what has been accomplished pale before our wonder and admiration at what will surely be accomplished. Progress is marching with rapid steps. Looking forward to the future with the light the past affords us, we see the promise of great things to come. Let us welcome each new triumph of the discoverer and inventor, and take advantage of every resource that science can suggest. War is a sad necessity, but it comes seldom to a nation known to be prepared. Let us thoroughly prepare ourselves. Then, if war does unfortunately come, we need not fear the issue.

NOTES.

South of England Telephone Company.—The address of this company will in future be 50, Old Broad-street, London, E.C.

West Coast of America Telegraph Company.—This company have removed to their new offices, 50, Old Broad-street, London, E.C.

The Brazilian Submarine Telegraph Company.—The traffic returns of this company for the week ended 1st January amounted to £2,569.

Electric Telegraphs. — Taquin and Ettieyhausen, in Vienna, in 1836, erected an electric telegraph, the wires being partly overhead and partly underground.

Diary for the Watch.—Messrs. Kendal and Dent have prepared a little almanac to go inside the watch case. The specimens sent are, though small, quite clear.

Eastern Telegraph Company.—The traffic receipts of this company for the month of December amounted to £53,179, against £53,036 in the corresponding period of 1884.

Direct Spanish Telegraph Company.—The estimated traffic receipts of this company for the month of December, 1885, were £1,754, against £1,748 in the corresponding period of last year.

Eastern Extension Telegraph Company.—The traffic receipts of this company for the month of December, 1885, amounted to £34,785, and to £41,426 in the corresponding period of 1884.

The Telephone and Railway Signalling.—The telephone is being rapidly introduced on the German railway lines at places where the old electro magnetic signalling appliances can be superseded with advantage.

Personal.—The Royal Humane Society have lately awarded their bronze medal and certificate to Mr. Herbert Tomlinson, Demonstrator of Natural Philosophy at King's College, London, for saving a young girl from drowning at Seaford, Sussex.

Woodside Electric Works.—We have received the catalogue of the firm of J. D. F. Andrews and Co., Glasgow, giving full particulars as to the appliances and plant manufactured and sold by them in connection with Electric Lighting industry.

The Western and Brazilian Telegraph Company.—The traffic receipts of this company for the week ending 1st January, 1886, were £2,150, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

Great Northern Telegraph Company.—The traffic receipts of this company for December amounted to £20,280. From 1st January to 31st December, £284,720; against, in the corresponding months of 1884 and 1883, £276,280, and £254,480 respectively.

Mechanical Telephone at Dundee.—At a meeting of the Dundee Harbour Trusts on Monday, a Sub-Committee of the Works Committee was instructed to report as to the desirability of adopting the mechanical telephone for short distances at the Harbour.

The Patent Laws.—The first meeting of the Departmental Committee appointed by the President of the Board of Trade to inquire into the working of the Patent Laws will be held early next week. The inquiry is expected to be a protracted one, on account of the mass of detail involved.

The West India and Panama Telegraph Company.—The estimated traffic receipts of this company for the half month ended the 31st December are £2,017, as compared with £2,359 in the corresponding period of 1884. The September receipts, estimated at £3,876, realized £3,913.

Lancashire and Cheshire Telephone.—We have received from the Lancashire and Cheshire Telephonic Exchange Company a card almanac for office use, illustrated by pictures of the various instruments and apparatus used in telephony, the whole forming a neat and handy card for reference.

International Society of Electricians.—We notice from the *Proceedings* just received that it is intended to organise a series of public lectures to be given in the spring, which it is hoped will attract the same attention as those given at the Exhibition last year, which were held at the Observatory.

Chess by Telegraph.—An intercolonial chess match has been played by telegraph between New South Wales and Victoria, resulting in a win for the latter. Victoria won three games and lost one, while New South Wales won one and lost three. The other two games were unfinished, both being in favour of Victoria.

Sir Henry Bessemer.—It is not generally known that this gentleman, whose greatest successes have been won in other directions, was an earnest worker and one of the pioneers in electro-deposition. About 1834 he electro-deposited copper on lead castings so as to produce antique heads in relief for mantelpiece ornaments.

Silicium Bronze.—We shall be glad if our readers will send us information relating their experience in the use of this wire for electrical purposes. We have, during the past year, received information that it is not trustworthy material, but as no doubt many people have used it, greater experience will enable us to somewhat decide the question.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of this company during the month of December was 3,023, estimated to produce £2,450, against 3,001 messages, producing £2,553 in the corresponding month of last year. The traffic receipts for the month of September, estimated at £2,100, realised £2,160.

Electricity at the Antwerp Exhibition.—We have received from M. Charles Mourlon, a report of about 300 pages dealing with the electrical exhibits at the recent Exhibition at Antwerp. The majority of the exhibits present little or nothing new, but, nevertheless, they have been described in a very interesting manner by the author of this report.

Thermo-Electricity.—Little attention is paid to this branch of electrical investigation, but although, as Lord Rayleigh has shown, we cannot expect great things from it, there surely remains much that can be done. Have we really advanced much beyond the rudiments? Thermo-electric batteries start from about the year 1832, when Dr. Botto, of Turin, made one out of platinum and iron.

Globe Telegraph and Trust Company.—The directors of this company have declared an interim dividend on and after the 18th inst. of three shillings per share on the preference shares, less income tax, and of one shilling and sixpence per share on the ordinary shares (income tax having already been deducted) for the quarter ending the 18th January, 1886. The transfer books are to be closed from the 11th to the 18th January, both days inclusive.

Digitized by Google

Electric Light Installation.—Messrs. Colville and Sons have resolved to introduce the electric light into their extensive iron and steel works at Motherwell, and Messrs. Norman and Sons, Glasgow, have been instructed to fit 200 incandescent lights and 32 arc lamps. These are guaranteed to burn for a period of eighteen hours at a stretch. The new screw steam yacht "Mohican," belonging to Mr. John Clark, Paisley, has also been fitted up with the electric light.

Earthquake in South Devonshire.—The neighbourhood of Dartmouth and Kingsbridge was visited by a slight shock of earthquake on Monday forenoon at twenty minutes past ten. At Stoke Fleming a number of persons felt the vibration, and at Stokeferry some little damage was done by it. The phenomenon was most severely experienced at Torcross, where much alarm was created, especially in houses near the beach. At Stoneham, Chillington, and Frogmore, slight oscillations were also experienced.

Lighting a Christmas Tree.—At a children's evening party given by Mr. Albert Kisch, of 3, Sutherland-avenue, W., nearly a hundred children being present, a large Christmas tree was successfully lighted by means of the electric light by Messrs. Woodhouse and Rawson, thus giving the whole a most striking effect without the slightest danger of fire or destruction to the handsome presents borne by its branches. The current was supplied from accumulators placed in the corner of the room.

The Electric Lighting Act.—According to the *Standard* the only Bill before the new Parliament relating to the electric light is promoted by the West London Electric Lighting Company, which asks for an extension of time within which to carry out the powers conferred upon them by several provisional orders, which have from time to time been granted to the Company under the Electric Lighting Act of 1882. They also seek to exempt themselves from certain provisions in that Act, which define the terms upon which electricity shall be supplied.

Magnetised Cables.—Advices from America state that tests made of the elevated railway structure and the Brooklyn bridge cables, East River Bridge, show that they are magnetised. The induced magnetism from the earth is supposed to have been fixed by the jarring to which these structures have been subjected while under magnetic influences. The bottom parts of all the pieces of iron thus magnetised show north polarity, and the cables of the bridge are said to be magnetised in the direction of their diameter; the upper surface of the cables throughout their length, being of south polarity, and the lower surface of north polarity.

Advertisers and Battery Supplies.—The replies to Mr. F. Issels' inquiry are almost all from firms and companies in advertisement of their own wares. We rather expected this would be the case. Letters containing similar inquiries reach us constantly and are generally answered privately. In America the firms who supply such wares advertise them in the ordinary way. In England the great desire seems to be to get the wares advertised for nothing. Some of the letters received have been sent to our correspondent by post, as we must emphatically decline to make our correspondence pages the place for advertisements.

Telegraphic Communication with the Continent.—At a meeting of the Liverpool Chamber of Commerce, the subject of improved telegraphic communication with the Continent was brought up, and a memorial to the Postmaster-General was adopted, pointing out that owing to the many sectional divisions of wires and cables, and the complicated arrangements existing in the Exchange Telegraph Office, serious delays take place in messages sent from Liverpool to Hamburg, Berlin, Havre, Paris, Frankfort, Vienna, Milan, Moscow, and St. Petersburg, and suggesting that nothing short of an adequate provision of direct wires from Liverpool to the principal Continental cities would remedy the evils complained of.

The Tape System.—The petition presented to the Stock Exchange Committee, says *The Times*, the object of which is to restrict the delivery of prices by the Exchange Telegraph Co. to members and such other persons, if any, as may be privileged by the Stock Exchange, was considered on the 6th inst. We understand that evidence was produced which was strongly in favour of the Exchange Telegraph Company being given an official *status* in the House, under certain conditions, but that the committee decided to adjourn the matter to a future day. Negotiations with the Exchange Telegraph Company are, we believe, going on informally on behalf of the Stock Exchange Committee, and the result will probably be known shortly.

Underground Wires.—The Standard Underground Cable Company, of Pittsburg, U.S., have lately laid an experimental electrical cable, connecting the headquarters of the police and fire departments. A trench about 4ft. deep was dug along the gutter, in which a wooden box to contain the cables will be laid. The cables consist of six insulated copper wires pressed in a malleable lead pipe and laid side by side in the boxes. The latter when closed up are to be covered with roofing pitch. All the wires of the fire alarm telegraph running out of the headquarters in Mercer-street are to be removed from the tall masts in front of the building and connected with the underground cables, and the police telegraph wires are to be similarly treated.

The Telegraph and Lighthouses.—At a meeting of the Works Committee of the Dundee Harbour Trustees, the engineer called attention to the unsatisfactory nature of the telegraphic communication between the Dock Office at Dundee and Buddonness High Lighthouse, and the committee recommended that the telegraph wire between Earl Grey Dock Office and the High Light at Buddonness be disconnected from the instrument at the Coastguard Station at Broughty Ferry, and so form one uninterrupted line between the Dock Gate House and the Lighthouse, and that a connection be effected between the Dock Gate House and the Coastguard Station by means of the National Telephone Company's system. At a meeting of the Harbour Trust on Monday, the recommendation of the committee was approved.

Early Patents.—The earliest patent mentioned in the "Abridgments of Specifications" relating to electric or magnetic subjects is that of Gowin (or Gowan) Knight, dated June 10th, 1876, and relates to the construction of compasses so as to prevent them being affected by the motion of the ship; in fact, most of the earlier patents relate to compasses. It is interesting to notice, however, that in these early days of patents the applications of electricity physiologically were studied, for Edward Nairne in 1782 patented an invention to affect the body in any part with either kind of electricity, and Benjamin Douglas Perkins in 1798 professed to cure aches, pains, and diseases in the human body by drawing certain metals over the parts affected. Henry Pinkus in 1834 embodies in his patent the use of magnetic attraction to propel carriages.

The Snow Storm and Overhead Wires.—The daily papers will have called sufficient attention to the damage to overhead wires caused by the snow storm of Wednesday last in the London district. As might be expected, both telephonic

Digitized by Google

and telegraphic communications were considerably interrupted. Communication of this kind has become an essential part of civilised life, and we are so accustomed to rely upon a certainty of telegraphic communication that when a breakdown occurs we feel it the more keenly. With regard to telephony we have always contended that the system pursued, instead of developing one of the greatest of modern discoveries, is really keeping it back. We should like to see the telephone in every house. We think if a right system were adopted, that a few years would see its use so extensive that a house without it would be the exception and not the rule. It is not only the cost which arises from the damage done by snow storms, but the discredit which attaches when the instrument fails at a time it is most needed.

SINGAPORE.—The introduction of the electric light into this colony may now be accepted as an accomplished fact, says the *Straits Times*. Mr. E. J. Wells has been exhibiting the latest form of the incandescent lamp at his works in River Valley Road for some weeks, and he is waiting the arrival of suitable machinery in order to exhibit the more powerful arc lamp. Mr. Wells is also in course of forming a company, to be called the Singapore and Straits Electric Light Company (Limited), for the purpose of furnishing the necessary capital to carry out the lighting of private dwelling houses and public buildings in the colony and the native states on an extensive scale, and he has already obtained from the Municipal Commissioners a concession of the right to lay wire in one district of the town, and a promise of a further concession so soon as the company is registered. It may here be noted as a curious circumstance that it is to the same gentleman who is now introducing the electric light into the Colony that Singapore was indebted for the introduction of gas about 24 years ago.

SOCIETY OF ARTS.—The following papers are announced for reading before the Society of Arts at meetings previous to Easter:—At the ordinary meetings on Wednesday evenings, at 8 o'clock:—"Results of Experiments on Mechanical Motors for Tramways made by the Commission at the Antwerp Exhibition," by Capt. Douglas Galton, D.C.L., C.B., F.R.S. (Sir Frederick Abel, D.C.L., C.B., F.R.S., chairman of the society's council, will preside); "Machinery in Mines," by Henry Davey (Sir Frederick Bramwell, F.R.S., Pres.Inst.C.E., will preside); "Artistic Bronze Casting," by George Simonds; "Calculating Machines," by C. V. Boys; "Domestic Electric Lighting," by W. H. Preece, F.R.S.; "The Experiments with Lighthouse Illuminants at the South Foreland," by E. Price Edwards. In the Applied Chemistry and Physics Section, on Thursday evenings, at 8 o'clock—"Magnetism of Ships and the Mariner's Compass," by Wm. Bottomley, jun.; "Photography and the Spectroscope in their Application to Chemical Analysis," by Prof. W. N. Hartley, F.R.S. The next course of Cantor Lectures will be by Prof. H. S. Hele Shaw, on "Friction."

"CHEMICAL ELECTRIC LIGHT."—A company appears to have been formed at Boston, Mass., for the purpose of manufacturing and supplying this singular commodity. The prospectus informs us, however, that the light is so called because it is obtained from a primary battery fed by Volta Pavia, a "new chemical." The name is certainly new; but of the chemical we can only make out for sure that it is sold at five dollars per gallon when there are any buyers. It is said that batteries containing this solution possess five times the efficiency of other primary batteries—which is not so sure; and that incandescent lamps can be maintained by it at "full candle-power" for 200 hours on one solution without renewal—which is rather vague; and lastly, that Volta Pavia in a medical battery has done "consecutive work for three months, which formerly required replenishing every week"—which is rather ungrammatical. The trade mark of this enterprising firm is a pair of frog's legs in convulsions, delicately intended as an allusion to Volta, but in their present relation more likely to remind us of that ingenious speculator the owner of the Jumping Frog.

THE ANGLO-AMERICAN TELEGRAPH COMPANY AND ITS SHAREHOLDERS.—We are strongly of the opinion that the action of the shareholders, or rather of a section of the shareholders, as reported in another column, is ill-considered and ill-advised. It is impossible for us to enter into any lengthy discussion as to the policy of the directors—they must combat the criticism themselves; but when all the conditions of Atlantic telegraphy are considered it is difficult to suggest a better policy. On one point we shall speak, and that is as to the reserve fund. The existing fund is not large enough, and the directors are perfectly justified in increasing it, even to double its present amount. The shareholders should consider that their property has been attacked again and again of late years; that opposition has sprung up; that the carrying capacities of the Atlantic cables are far in excess of the requirements; and instead of staying the hands of their directors the shareholders should give them full powers. Just when the directors are in the greatest straits as to the best course to be pursued, the shareholders, knowing but little of the real position, precipitately interfere—a policy which, if persisted in, will end in disaster.

ELECTRIC ACCUMULATORS.—In 1883 the Academy of Mining and Forestry in Schemnitz, Hungary, was furnished with incandescent lamps, the electric current being supplied by about 90 accumulators. A paper by S. Schenek and S. Farbaky describes the construction of the accumulators employed, and gives an account of some observations made by the authors. To study the behaviour of the sulphuric acid during the condensation of the discharge of the current a series of experiments was made. It was found that when the accumulators are charged the sulphates are decomposed, sulphuric acid being liberated; whilst on discharging, the sulphates are again formed, the free acid being recombined. To determine the ratio of accumulated energy to acid set free, and the ratio of discharged energy to acid fixed, a further series of trials had to be made. The results appear to show that when the accumulators are charged 2·23 grams of sulphuric acid are liberated per ampere per hour, and that during their discharge 2·25 grams of acid are fixed, giving a mean value of 2·24. The authors term this number the electro-chemical equivalent of sulphuric acid for an electric force of one ampere per hour. From this value some useful data in regard to the preparation, treatment, and application of electric accumulators are said to be derived.

THE TELEPHONE QUESTION.—Writing to the *Scientific American* on this question, Mr. Berliner says:—"Reis telephones, when used *as described by him*, will not transmit speech. He who invents a new *art* is entitled to the fame and financial success based upon a patent for such an art. If the assertions that Reis *did* occasionally understand spoken words be true, that did not constitute the art of speaking, because an art is something that can be *controlled*, and Reis then only spoke because the action of his transmitter occasionally was *beyond* his control. Five years before Reis made his instruments, their principle was *fully published in a prominent scientific paper in the city where he then lived, under the name 'telephony,' and he was then an active*

Digitized by Google

member of the physical society of that place. Those principles were first accurately expounded by Charles Bourseul, of whom said publication spoke. The method of producing undulations by immersing an electrode in liquid, which is the subject of Mr. Gray's caveat, was described in Mr. Bell's original application, which was sworn to several weeks before Mr. Gray's caveat was *written.* Hence it is absurd to assert that Mr. Bell obtained that idea from Mr. Gray's caveat. That we can *now* speak with the Reis instruments is no more proof in favour of Reis than the fact that we can also *now* speak with a Morse key and sounder is a proof that Morse invented the art of speaking by electricity. Both, together with other electrical instruments, can to-day be manipulated on Bell's principles so as to transmit and receive speech."

Royal Institution of Great Britain.—The winter programme in connection with the Royal Institution opens with a series of Christmas lectures by Prof. Dewar on the story of a meteorite, and the list of lectures down till Easter next includes such names as those of Dr. Ball, Astronomer Royal of Ireland, whose subject is the astronomical theory of the great ice age; Mr. R. S. Poole, Mr. C. T. Newton, Prof. A. Gamgee, Mr. W. C. Roberts-Austen, Prof. W. Boyd Dawkins, Prof. Tyndall (who gives four lectures on light), Mr. Archibald Geikie, and Dr. Taylor, of St. John's College, Cambridge. The Friday evening meetings begin on Jan. 22, when Prof. Tyndall discourses on "Thomas Young and the Wave Theory," and the programme of probable arrangements is one of sustained interest. The Royal Institution, as is well known, is an association of individuals who are devoted to science and desirous to promote its advancement. It includes two laboratories for the promotion of chemical and physical science. In the physical laboratory the researches of Prof. Davy, of Prof. Faraday, and of Prof. Tyndall were conducted; while in the chemical laboratory Prof. Falkland made some of his most important researches in organic chemistry; and more recently Prof. Dewar has conducted his spectroscopic researches and his experiments relating to the chemistry of the electric arc and the condensability of gases. Both forms of the electric light, the voltaic arc and the magneto-electric spark, were, indeed, first introduced at the Royal Institution by Davy and Faraday. In addition to the public lectures and the weekly meetings of the members, there are a model room, containing scientific apparatus of historical interest and of present use; a library of about 50,000 volumes, a reading room for study, and a newspaper room. It only remains to be added that the institution is self-supporting, and has never received any aid from Government.

As Others See Us.—Our contemporary, *The Journal of Gas Lighting*, in its summary of the year's work, says:—"With regard to the electric light, upon which we have considered it our duty to keep watch from week to week, there is little to be said that will give satisfaction to its supporters. The history of 1885 is the same as that of 1884, 'only much more so.' Very few companies connected with electric lighting as a business remain solvent; and these keep afloat by the comparatively small amount of trade which they can secure in the way of making and dealing in electrical machinery. Electric lighting, as a business independent of the trade in apparatus, does not at this time exist in Great Britain. Not one of all the Provisional Orders and licenses granted by the Board of Trade under the Electric Lighting Act has been carried out by the undertakers; and there is not the slightest likelihood of any improvement in this respect. The blame for this utter collapse of electric lighting as a business has been ascribed to the socialistic purchase clauses of the Electric Lighting Act; and there is a rumour afloat that these are to be amended in the next session of Parliament. It is impossible for those who are interested in industries protected by statute to regret that discredit has thus been thrown upon Mr. Chamberlain's confiscatory legislation, because it will tend to discourage fresh movements in the same line, having for their object the retrenchment of statutory privileges already granted. It may well occur to those most given to cry out in condemnation of what they are pleased to call 'monopolies' that, after all, the supply of a thing under a regulated monopoly may be preferable to no supply at all. The lesson should not be allowed to pass unheeded. At the same time, the electricians who swarmed into the Board of Trade with applications for Provisional Orders immediately after the passing of the Act, knowing perfectly well what were its provisions, are not justified in declaring that it has destroyed their occupation. What the Act undoubtedly did destroy was a host of speculative companies which, with limited and encumbered capitals, presumed to apply for right to take possession of all the towns of the United Kingdom. It has been rightly said that the Electric Lighting Act does not apply to the entire universe; and when electricians can show that they enjoy in Bombay or Melbourne, in Florence or Amiens, a success which is denied them here, the offending law will soon be repealed. How long would a law remain on the Statute Book if the capitalists of England were assured that it, and it alone, stood in the way of a profitable employment of the idle gold which fills their coffers to overflowing? There has certainly been some progress in electric lighting; but it has been in the improvement of details of apparatus and arrangement in the hands of private firms, who do the greater part of such legitimate work of this kind as is required. Desperate attempts have been made to claim success for the transmission of force by electrical currents, according to a system imagined by M. Marcel Deprez. The genuineness of the results obtained by Deprez has been questioned; and the latest news concerning the experiments is that there has been a serious breakdown, accompanied by much damage to machinery. There is no longer any talk of primary batteries for domestic lighting which will pay for the light by the value of the residuals of the cells; and a practical meter is still to seek." The whole of the above is so evidently biassed that we who know how utterly fallacious are the various statements can afford to say "let those laugh who win." From first to last this trade contemporary has perverted the truth, and those who trust it will lamentably suffer in the long run.

Development of Electricity.—M. E. Dorn, in *Wiedemann's Annalen*, has given the following experimental proof of the law that both electricities are developed at the same time and in the same quantities, for pyroelectricity. According to the *Phil. Mag.* he says:—"That both electricities are produced in equal quantities in all cases of electrical excitation is a principle generally admitted, though the experimental proofs are not numerous. It appeared to me desirable, therefore, to prove the above principle for pyroelectricity, particularly as here an apparently paradoxical case occurs. If a crystal of tourmaline is warmed at one end and then rapidly passed through the flame, it is first found to be almost entirely unelectrical. As it cools somewhat, considerable disengagements of electricity occur which are occasionally *of the same kind at both ends.* The above principle requires that the same kind of electricity occur in equal quantity on the lateral faces, or in the interior of the crystal. A test is furnished by the principle, that a quantity of + electricity in the interior of a shell-shaped conductor would induce − electricity on its inner, and + electricity on its outer side, whatever was the distribution

Digitized by Google

of the original + electricity. If the tourmaline, after being heated, is brought inside a conducting but insulated hollow body, an electrometer connected with the latter should show no signs of electricity as the crystal cools. The arrangement of the experiment was as follows:—A brass cylinder, 4 centimetres in height and 2 centimetres in diameter, was supported on a rod of shellac, and had a lid which could be lifted off by means of an insulating rod of shellac. A third rod of shellac was fixed to the under surface of the lid, and in it was fused a thin brass wire which was wrapped round the tourmaline. The tourmaline used was of a green colour, very transparent, fractured on both sides, and for a length of 2·05 centimetre weighed 1·59 gramme. One pair of quadrants of the electrometer was put to earth. A volt was represented by a deflection of about 2·5 centimetre on the scale, at a distance of 130 centimetres, which was sufficient for the present purpose. It was more important that the insulation of the one pair of quadrants should be good, and that it should not receive a charge from the movable part of the electrometer, or from the air in the room, than that the electrometer should be very sensitive. These conditions were more than sufficiently satisfied. For when electricity was imparted to the insulated pair of quadrants, the deflection only sank in forty minutes from 14·0 to 13·3; and further, after insulation for three quarters of an hour without charge, there was a deflection of 0·4 centimetre. The shellac rod which supported the cylinder also insulated well; for after being connected with the insulated pair of quadrants, the deflection sank in eleven minutes from 38·2 to 30·4. The capacity of the insulated pair of quadrants was found in several experiments to be about seven times as great as that of the cylinder. In the experiments the second pair of quadrants, from which a wire passed to the cylinder, was connected with that to earth. The lid with the crystal was raised, the latter heated in one end of the flame of a Bunsen burner or spirit lamp, again brought into its place, and the connection with the two pairs of quadrants rapidly broken. However the heating was arranged, no deflection was ever obtained which exceeded the uncertainty of the instrument, although the quantities of electricity developed were often considerable, and were frequently of the same kind at both ends. From a long series of experiments I select the following:—When the crystal was heated at one end, and after a minute removed from the cylinder, the proof plane applied to the crystal and then to the insulated pair of quadrants showed negative electricity at both ends, the deflections at the top and bottom being 3·0 and 7·50 centim. respectively. In another case there was no apparent electricity at one end, while that of the lower sent the image out of the field. If the duration of heating was somewhat greater, and the crystal remained longer in the cylinder, there was on the top positive, and on the bottom negative, and of such strength that often, on raising the lid with the crystal, the luminous image disappeared from the scale, which is simply explained by the fact that part of the electricity induced on the cylinder is removed with the lid."

Information for the People.—The following has appeared in one of the Sheffield papers:—"We have lately had the opportunity of ascertaining a few practical details about the electric light as applied to works, which may be interesting at the present time of year. As most persons interested are now aware, there are two distinct systems of electric light—the arc, in which a brilliant bluish-white light is given by the glowing ends of two carbon rods, and the incandescent, in which a light is given by a long thin filament of carbonised thread, which is made white-hot throughout its whole length by the electricity. This filament is enclosed in a glass globe, from which all air is exhausted. The incandescent system is the one which seems to commend itself for use in mills, the lamps giving a steady manageable light equal to about 16 candles. In the latest form of lamp the thin filament is made from carbonised cotton thread, in the form of a curl, to give equal illumination all round, the ends finished off in a socket, by which it is easily fitted into the holder. This is the most practical form, and is the outcome of the union of the two best known systems invented by T. A. Edison, in America, and J. W. Swan, in England. The electricity for these lamps is not of very high pressure, and there is no danger from shocks on touching the wires, as there is in some other systems. No matches are required, the lamps all lighting together when the dynamo is started; but each lamp can be controlled, if necessary, by its own knob, and turned off and on like an ordinary gas-burner. Being enclosed in a glass globe there are no fumes, no dirt, and very little heat. It can thus be placed close to the worker, or amongst inflammable materials. If the glass breaks the lamp goes out. Moreover, to prevent danger from escape of electricity, each lamp is controlled by a piece of fusible wire which melts and breaks all contact if by accident too much electricity tends to pass. Practically about eight lamps can be kept alight for each indicated horse-power, allowing for all loss; thus for 100 lights a 6 horse-power nominal indicating about 12 horse-power would be required. For the uninitiated who wonder how the motion of a belt turning a pulley can be converted into electricity, we may say that the whole development of electric light is founded on a simple experiment of Faraday, who found that if a coil of wire is moved near a magnet, a current of electricity flows as long as the motion is kept up. The magnets of the dynamo are made very strong, and numerous coils of wire are mounted so as to be turned very quickly (800 per minute) between the very poles of the magnet; each wire as it passes gets its shock and pours little currents into the main cable, something like the water buckets on a chain pump. Where water-power is available there is hardly any expense for maintenance; the electric machinery, spinning merely in air between magnets, has very little wear and tear, save at the brushes when the electricity is taken off. These cost a few shillings a year. The only real expense is for replacement of lamps, and these last over 1,000 working hours, and of course require replacing only according to length of time burnt. Where steam-power is used the cost of fuel has to be added, but experience shows that even then, in a large mill, the saving is often considerable over gas. One great advantage is that, when required for sorting, a few lamps could be easily arranged to be run over the usual power; they then give a beautiful white light, nearer to daylight than any other artificial light. Large numbers of mills and public and private buildings have lately adopted the light, the feeling of hesitation as to its capability having now worn off. The display at the Inventions Exhibition itself gave a complete answer to those who imagine that no real progress has been made. The Metropolitan stations, Cannon-street, Monument, Eastcheap, and others, also Paddington and Waterloo, are lighted by this means. The Bank of England, House of Commons, Royal Courts of Justice, Inner Temple, and many theatres have adopted the light. Amongst manufacturers, Colmans, of Norwich, and J. and P. Coats, the Paisley cotton thread spinners, are using the light, the latter having 1,200 lamps, and they are adding thereto. We are told that the principal factory of these lamps is making them at the rate of half a million a year. It is evident, then, that though the Utopia of public supply has not yet arrived, great development has taken place."

THE WINDING OF VOLTMETERS.*

BY PROFESSORS W. E. AYRTON, F.R.S., AND JOHN PERRY, F.R.S.

(*Concluded from page* 156.)

IV. Making b equal to nought as the least value of b attainable, we can now find the value of a to make the error a minimum. To do this we must put b equal to nought, take d equal to -1 in (9), differentiate with respect to a, and equate the result to 0.

Thus $$\phi(m)+\phi(n)-2\phi(p)=0 \quad . \quad . \quad . \quad (18)$$

where $\phi(a)$ has the signification given to it in (17).

Since $b=0$

and $d=-1$

it follows from (14) that
$$\left.\begin{aligned} m&=2-2a \\ n&=-a \\ p&=2-4a_1 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (19)$$

therefore, from (17)
$$\phi(2-2a)+\phi(-a)-2\phi(2-4a)=0.$$

The equation cannot be solved generally, but by giving various values to a we can find which of these values makes the expression on the left hand side most nearly equal to nought, and to ascertain the value of the function for each of the values of a we can conveniently use the curve connecting $\phi(a)$ and a previously employed.

For $a=0{\cdot}5$ we have
$$\phi(1)+\phi(-0{\cdot}5)-2\phi(0)=1{\cdot}375+0{\cdot}865-2\times1{\cdot}04$$
$$=+0{\cdot}16,$$

for $a=0{\cdot}4$ we have
$$\phi(1{\cdot}2)+\phi(-0{\cdot}4)-2\phi(0{\cdot}4)=1{\cdot}43+0{\cdot}9-2\times1{\cdot}182$$
$$=-0{\cdot}034,$$

for $a=0{\cdot}3$ we have
$$\phi(1{\cdot}4)+\phi(-0{\cdot}3)-2\phi(0{\cdot}8)=1{\cdot}48+0{\cdot}936-2\times1{\cdot}311$$
$$=-0{\cdot}206,$$

for $a=0{\cdot}2$ we have
$$\phi(1{\cdot}6)+\phi(-0{\cdot}2)-2\phi(1{\cdot}2)=1{\cdot}53+0{\cdot}97-2\times1{\cdot}43$$
$$=-0{\cdot}36.$$

Plotting these points, we find (Fig. 2) that the curve for the

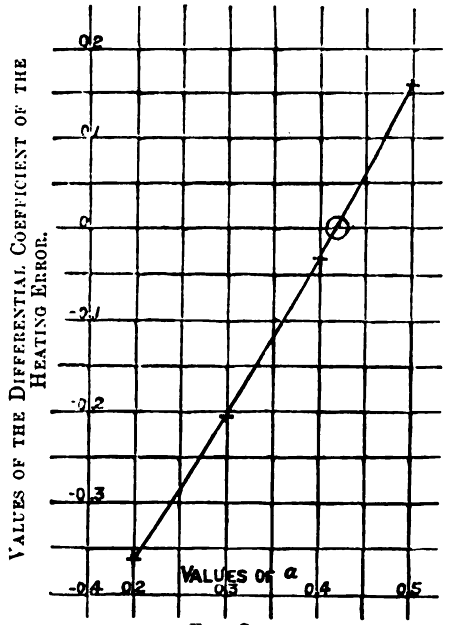

FIG. 2.

differential coefficient cuts the axis along which a is measured at a point 0, for which a has the value 0·42, or, in other words, *a equal to 0·42 makes the differential coefficient equal to nought, and hence is the value of a that makes the heating error a minimum.*

* Paper read before Physical Society.

As a check on this we have drawn the curve for the values of the heating error for different values of a (Fig. 3), and from this also it is seen that the heating error has a minimum when a equals 0·42. Hence it follows that the law of increase of the sectional area of the wire with the radius of the convolutions should in our solenoid voltmeter follow the law
$$x=x_0\,r^{0{\cdot}42}$$
in order that the error due to heating may be a minimum.

Fig. 3 not only gives the value of a that makes the heating error a minimum, but it shows by how much the heating error is increased if a has a value greater or less than 0·42. For example, if a equals 0—that is to say, if the voltmeter be all wound with wire of the same gauge—then continuing the

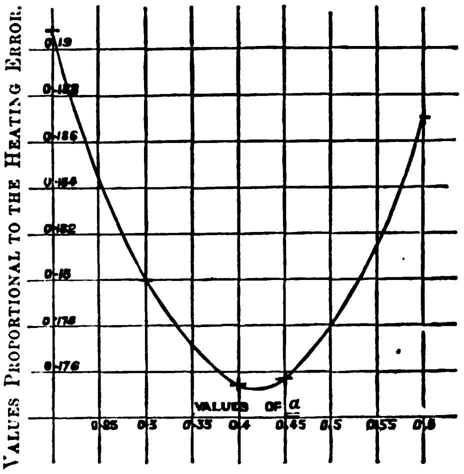

FIG. 3.

curve backwards we find that the heating error is increased by about one-third.

V. One plan of diminishing the heating error with voltmeters, and one that we have frequently employed, is to place in the same circuit with the instrument a coil wound with German silver wire, and having a resistance far greater than that of the voltmeter itself. By using wire of large diameter wound on a bobbin of large volume, and with as efficient arrangement for cooling as can be conveniently employed, the heating error can be rendered extremely small. Such a bobbin, however, is both costly and bulky, and the employment of such an outside resistance coil wastes energy, and can only be used with voltmeters in electric light and power installations where such a waste of energy is unimportant. The following investigation has, therefore, been made for the purpose of determining what must be the volume of this outside resistance coil, and what must be its resistance relatively to that of the voltmeter coil so that the heating error may not exceed any given value.

Let R be the resistance of the coil of copper wire wound on a voltmeter, let H be the rate of production of heat when the maximum deflection is obtained, then, as already shown, H will be constant for a voltmeter of a given size wound according to a definite law, whether it be wound with fine wire for a 500-volt instrument, or with thicker wire for a 50-volt one. Let C be the current passing round it when this maximum deflection is being produced, then
$$C^2\,R = H \text{ a constant.}$$

Let the increase of resistance produced by the passage of the current for some time be r, then $\frac{r}{R}$ is proportional to the product of γ, the coefficient of increase of the resistance of copper per degree of temperature into H, since, as already explained, the voltmeter is so wound that the rate of production of heat is proportional to the increase of temperature. Hence
$$\frac{r}{R} = \text{a constant, A, say.}$$

Now, let there be a resistance coil of German silver wire of uniform cross section of volume V in series with the instru-

Digitized by Google

ment, and let us suppose that for any coils thus added the rise of temperature is proportional to the energy wasted per second per unit volume—that is to say, proportional to the rate of production of heat per unit volume.

Let R_1 be the resistance of this added coil, then $\frac{C^2 R_1}{V}$ is proportional to its rise of temperature; hence, if r_1 be the increase of resistance and γ_1 the coefficient of increase of resistance of German silver per degree—

$$\frac{r_1}{R_1} \propto \gamma_1 \frac{C^2 R_1}{V},$$

$$\text{or } r_1 = B \frac{C^2 R_1^2}{V} \text{ say, where B is a constant.}$$

Hence, if e is the error due to the proportional change of resistance—

$$e = \frac{r + r_1}{R + R_1},$$

$$= \frac{AR + B\frac{C^2 R_1^2}{V}}{R + R_1}$$

Let

$$\frac{R_1}{R} = y,$$

then

$$e = \frac{A + \frac{B}{V} y^2}{1 + y} \quad . \quad . \quad . \quad . \quad . \quad (20)$$

To determine the value of these constants, A and B, we may proceed as follows:—Wind a voltmeter according to the law which is to be adopted with any or no resistance coil outside, find the potential differences P_1 and P_2 required to produce the maximum reading of the instrument—

1st. Immediately or making connection.

2nd. After connection has been made for some time;

then

$$e = \frac{P_2 - P_1}{P_1}$$

Let e be experimentally determined in two cases, one when there is no resistance coil outside, and the other when there is such an auxiliary resistance coil obtaining values e_1 and e_2 respectively. Measure y_1, that is the ratio of R_1 to R, and also V. Then from the equations

$$e_1 = A,$$

$$e_2 = \frac{A + \frac{B}{V} y^2}{1 + y}$$

the values of the constants A and B can be determined, and when determined the error arising with the employment of an outside resistance coil of any resistance and of any volume can be calculated from (20).

It is obvious that as V becomes greater the error becomes less and less, but there is a practical inconvenience n largely adding to the weight of the instrument.

VI. *To determine the best resistance to give to the outside coil of given volume.*—When V is fixed e is a maximum or minimum when

$$\frac{de}{dy} = 0.$$

Now

$$\frac{de}{dy} = \frac{\frac{B}{V} y^2 + 2\frac{B}{V} y - A}{(1 + y)^2},$$

and

$$\frac{d^2 e}{dy^2} = \frac{2\left(\frac{B}{V} + A\right)}{(1 + y)^3},$$

y must be positive, therefore $(1 + y)^3$ is positive, also A and B are both positive, therefore $\frac{d^2 e}{dy^2}$ is positive, and therefore e is a minimum when

$$\frac{de}{dy} = 0,$$

that is when

$$\frac{B}{V} y^2 + 2\frac{B}{V} y - A = 0,$$

or

$$y = -1 \pm \sqrt{1 + \frac{AV}{B}},$$

but y cannot be negative, therefore only the positive sign can be used, or

$$y = \sqrt{1 + \frac{AV}{B}} - 1 \quad . \quad . \quad . \quad . \quad (21)$$

makes e a minimum.

Substituting this value of y in (20) we find that

$$e = 2\frac{A + \frac{B}{V} - \sqrt{1 + \frac{AV}{B}}}{\sqrt{1 + \frac{AV}{B}}} \quad . \quad . \quad (22)$$

VII. *To determine the best volume and the best resistance to give to the outside coil for a given permissible error.*—From the preceding it is easy to see that if the maximum allowable value of e is given, the minimum value of the volume that can be employed is given from (22), and for this value of the volume, the best value of y—that is, the best ratio of the resistance of the outside coil to that of the magnetising coil of the voltmeter—can be calculated from (21).

VIII. *To determine the sectional area to be given to the inner wire of a voltmeter in terms of the maximum potential difference, so as to make the heating error a minimum.* By experiment ascertain the potential difference P, that is necessary to produce the maxi-mum deflection with any voltmeter of the shape and size to be employed, and wound according to the law

$$x = x_0 r^a,$$

where a has the value that makes the heating error a minimum, and which value will depend on the shape and size of the instrument, and may be calculated for any special type of voltmeter in the same way as it has been calculated in what precedes for the long range magnifying spring instrument. Then, if it is desired to wind another instrument, of the same volume and shape, so that it will have its maximum deflection given by P_2 volts, it follows, since the heating will, as already proved, be the same in the two instruments for their maximum deflections, that their resistances must be proportional to the squares of P_1 and P_2, and hence from (5), since the same law of winding is followed, that the cross section of the innermost layer of wire in the two instruments must be inversely proportional to P_1 and P_2.

To have the same heating error in the two cases, with outside resistance coils of the same shape and size, it follows from (21) that it is necessary to use the same ratio between the resistance of the outside coil and the resistance of the magnetising coil. To have a less or greater heating error in the second than in the first case for the maximum deflection, it is only necessary to determine from (22) (the constants of which have been deduced by experiment with the first instrument) the greater or less volume V of the outside resistance coil needed with the second instrument, and calculate the ratio y of the resistance of the outside coil to that of the magnetising coil by (21).

IX. As to the second error, arising from the sensibility of the instrument being temporarily varied by external magnetic disturbance, referred to in § I, this can be overcome in three distinct ways—by

1. Shielding the instrument by putting it in an iron case with very thick walls
2. Using a very powerful controlling field.
3. Using a motion of *translation*, and *not of rotation* for the coils in the instrument that is deflected by the current.

The first method, to be successful, requires that the iron case should be heavy and cumbersome, and makes it unsuitable for portable instruments. A very powerful controlling field necessitates a very powerful deflecting force, and so either makes the instrument unsensitive or necessitates a considerable expenditure of current energy in the instrument. The third

Digitized by Google

method, consisting in giving the deflected body a *motion of translation*, is the best, since, no matter how strong the disturbing magnetic field may be, provided it is uniform throughout the small space traversed by the deflected body in its motion, no increase nor diminution of the deflection will be caused by the outside magnetic field. For this reason we have adopted this third method in our magnifying spring instruments, and experiments show that the shielding produced in this way is even better than in our older form of instruments provided with a powerful permanent magnet.

X. As to the third error, arising from certain types of voltmeters altering in sensibility, so that their constants vary from time to time. This error arises from two causes. In some voltmeters, such as those in which a controlling permanent magnet is employed, there is an error which gradually comes on from the demagnetisation of this magnet—an error which is greatly increased by a mistaken careful regular employment of a keeper for the magnets when the instrument is not in use. This error can be avoided by dispensing with a permanent magnet and using a spring or a weight, or an electromagnet which is magnetised by the current to be measured. A second time error arises from the employment of iron in the instrument, and has the effect of making the indications of the instrument depend not merely on the current passing at the time of measurement, but also on the currents that have lately passed through the instrument. This error is especially marked in those instruments in which the controlling force, or the force tending to bring the needle back to zero, in opposition to the deflecting force, is produced by the attraction of an electromagnet containing a core of soft iron wire, and which, it is *assumed*, is magnetised to saturation by the current which it is our object to measure. With small currents, however, which produce deflections in the lower part of the scale, this iron core is not saturated, and differences in the values of the readings of as much as 30 to 40 per cent. are obtained, depending on whether it is an increasing or a decreasing current that is being measured with such an electro-magnetic instrument.

XI. The fourth error, arising from the Volt standard employed by various people differing several per cent. from one another has been hitherto a very serious matter. The standards employed have usually been—

1. The E.M.F. of a Daniell cell.
2. The E.M.F. of a Latimer Clark cell.
3. A standard depending on the electro-chemical equivalent of silver and the value of the legal ohm.
4. The indication of a voltmeter graduated by some well-known maker, but graduated in a way quite unknown, probably, to the user.

Standard 1 is vague unless the details of the method employed in setting up the Daniell cell are more carefully specified than heretofore; for example, Carpart, in some recent tests of the E.M.F. of a Daniell cell made out of a U tube, with a contraction in the lower part, found it to vary from 1·111 legal volts when the zinc sulphate solution had 25 per cent. of $Zn\,SO_4$, to 1·142 legal volts when the solution had only 3 per cent. of $Zn\,SO_4$. His method of testing is based on the electro-chemical equivalent of silver and the legal ohm, and as a proof of its accuracy he finds that the E.M.F. of a Latimer Clark cell is 1·434 volts. If, however, we compare his results for a Daniell cell with 1·072 volts, as found by Sir W. Thomson when the zinc sulphate solution had a sp. gr. of 1·2, we see how Daniell's cells differ among one another.*

The E.M.F. of a Latimer Clark cell has also some vagueness attached to it unless the temperature coefficient of variation of E.M.F. of the particular Latimer Clark cell is known and taken account of. Generally the users of these cells are contented to say that the E.M.F. of a Latimer Clark cell as determined by Lord Rayleigh is 1·435 true volts, or 1·438 legal volts, and they neglect the temperature variation altogether, which amounts to about 1 per cent. diminution per 12°C. elevation of temperature with certain Latimer Clark cells.

* Since the reading of this paper this subject has been very fully treated by Dr. Fleming in a paper "On the Use of Daniell Cell as a Standard of Electromotive Force," read before the Physical Society on June 27th, 1885.

Standard No. 3 is the one that we have used for some time, and, as we have obtained very satisfactory results with it, it may be well to describe our mode of using it a little in detail. First, by means of a large number of direct comparisons with a copper voltameter, we determine the most probable value in amperes of the indications in different parts of the scale of an ammeter *fixed permanently in position* by being screwed to the table. A current is now sent through this ammeter in series with a long thick copper wire having about six ohms resistance and wound in a large open coil. This coil has attached to its two ends the standard voltmeter, which is also fixed *permanently in position*. Simultaneous readings of the ammeter and voltmeter are now taken by two observers, when a signal is given and the bridge piece of a mercury commutator is moved so as to cut off the current and connect the copper wire together with the voltmeter, which is joined with it in parallel, to a differential galvanometer. Their *time* measurements, for about 10 minutes, are taken by a third observer of the parallel resistance of the thick copper wire and the attached voltmeter. Next a curve is drawn connecting the resistance of the cooling coil with the time, and on completing the curve backwards we ascertain with great accuracy, by interpolation, the resistance at the moment of stopping the current —that is, at the moment of making the simultaneous observations on the ammeter and voltmeter. Our copper wire is sufficiently thick that for a current of some 15 amperes passing through it, corresponding with about 80 volts maintained at its ends, the time curve of its resistance, obtained after stopping the main current, is nearly a straight line with hardly any inclination to the axis along which the time is measured; or, in other words, the change of resistance due to cooling while the measurements of resistance are being made is very small and easily allowed for, and the resistance in legal ohms, multiplied by the current passing in amperes, gives, of course, the potential difference in legal volts.

In using the copper voltameter to calibrate the ammeter it is of course necessary (in order that a firmly adherent deposit should be obtained) that the area of the immersed surfaces of the anode and cathode opposed to one another should exceed the limit given by Dr. Hammerl, viz., one square decimetre per 7 amperes, or rather more than two square inches per ampere, and in our experiments we have taken care to use a larger area in proportion to the current. Our negative plates consisted of a number of separate sheets of very thin hard copper, so that the weight of the deposit could be accurately measured; the current was supplied by accumulators, and increased or decreased by a carbon resistance, worked with a screw. By watching the ammeter and slightly turning this screw, one way or the other, the current could be kept very constant for a long time. The value of the electro-chemical equivalent employed for copper was 0·3295 milligramme per coulomb, which is deduced from the mean of the electro-chemical equivalent of silver, 1·118 milligramme per coulomb, as given by Lord Rayleigh, and 1·1183 by F. and W. Kohlrausch, and by using 63·47, 107·66, 32·07, and 16 as the atomic weights of copper, silver, sulphur, and oxygen respectively. The solution of copper sulphate employed was a saturated one, the crystals of copper sulphate used in making it being chemically pure.

To avoid errors being introduced by oxidation of the copper that had just been deposited on the copper plates, they were, on being taken out of the sulphate of copper bath, on the stoppage of the current, immediately washed quickly, first in water, secondly in alcohol, thirdly with ether poured over them, and then dried.

The current that a given set of accumulators will send through a copper voltameter depends, of course, partly on the distance between the alternate positive and negative plates, and partly on the depths to which they are immersed in the saturated solution of copper sulphate. The proper arrangements of the plates to allow any particular current to pass cannot conveniently be determined with the plates that are going to be used for the experiment, as an unknown weight of copper would be deposited on them during the process of adjustment, and great delay would be introduced if the plates had to be dried and weighed after the adjustment,

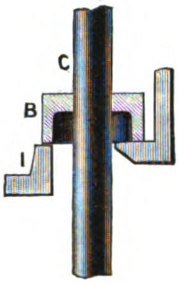
Digitized by Google

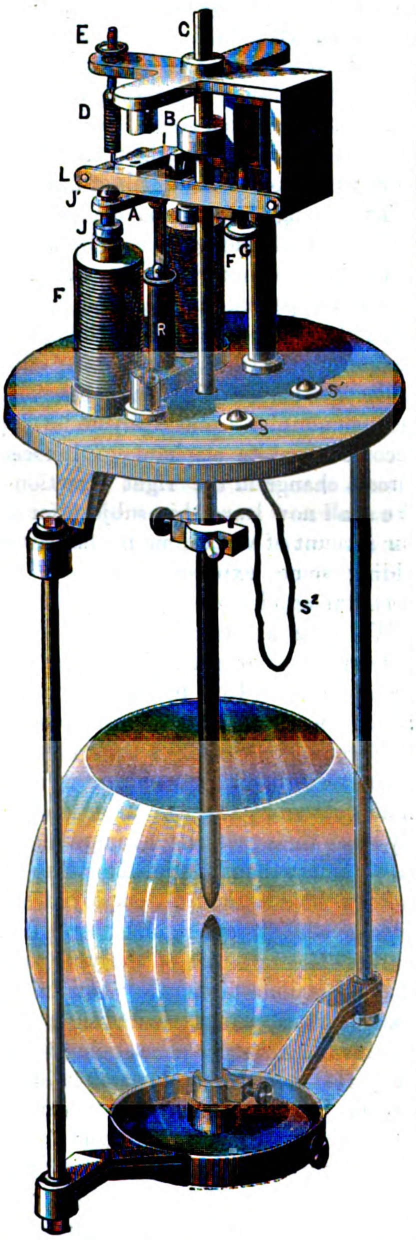
and before making the final experiment. Hence, after the proper plates to be used as the cathodes had been very carefully cleaned and weighed, a spare set of exactly the same size and shape were put into the bath, and their distance, as well as the carbon resistance adjusted, until the desired current was passing; then the spare set was removed, and the weighed set substituted for them, and the experiment carried out.

Having determined our volt-standard in the way above explained, we tested various voltmeters of different makers, and we fonnd that whereas the indication of some of them agreed very well with our standard, the indications of others differed by several per cent.

THE LEVER ARC LAMP.

We herewith illustrate the latest form of this lamp. A shows the armature, L a lever, and D a spring; E the nut for adjusting the tension of the spring D, and I a projection attached to

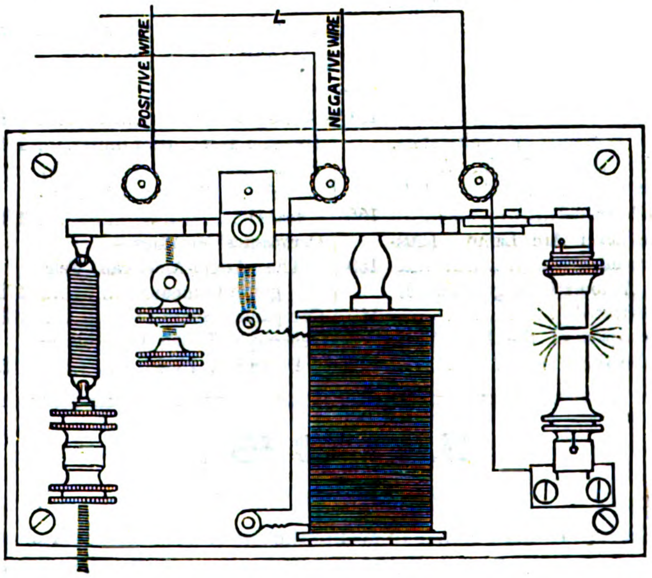




the lever L, which cants or tilts the clip B, by means of spring D; G is a set screw for adjusting the length of arc. The screws J J, with large heads passing through the armature A, serve as adjustable pole-pieces, and can be secured by means of lock nuts, J^1 J^1. R is the dash-pot, and S S^1 are the binding screws. The current entering at the positive binding screw S passes through the insulated flexible wire or cable S^2 to the upper carbon holder C, from thence through the arc and lower carbon, and through the frame of the lamp to negative binding screw S^1. The side rods are insulated from each other, and the ends of the coils of the electro-magnets F F are connected to the binding screws S S^1, thus placing the electro-magnet F in derivation from the arc. When the lamp is ready for action the carbon points are separated by means of the spring acting on the armature lever. The current takes effect upon the electro-magnet, which overcomes the force of the spring, thus loosening the clip and allowing the upper carbon to fall by gravity into contact with the lower one. The main circuit is thus completed, the spring overpowers the weakened magnetism of the electro-magnet, whereupon the spring again pulls up the lever, and with it the carbon rod, forming the arc. As the carbons burn distance between them becomes greater, and the resistance in the main circuit increases. This causes more current to pass through the shunt electro-magnet, which, becoming stronger, again attracts the armature and lowers the carbon rod. The lamp gives a steady and regular light.

AN AUTOMATIC REGULATOR.

In this instrument, designed by Messrs. Walker and Olliver, the electro-magnet shown is placed either in circuit with the supply wire or in shunt, as convenient. Its armature, whose motion towards the poles is opposed by an adjustable spring, carries a carbon contact, which on the arrival of an excess E.M.F. sufficient to overcome the mechanical resistance



opposed to the pull of the electro magnet, makes more or less firm contact with another carbon point in connection with a variable resistance, forming an additional path for the current. By forming the variable resistance of one or more incandescent lamps, the regulation of the by-path is said to be very perfect. A slight increase of E.M.F. produces light contact between the carbons, while, only a small current passing through the lamp, its resistance is only very slightly lowered. As the excess E.M.F. increases, the resistance offered by both the carbon contacts and the filament of the lamp decreases until the limit is reached for which the apparatus is arranged.

DRY ELECTRIC BATTERIES.—This paper, by W. V. Beetz, contains a series of determinations of the electromotive force of certain dry forms of Daniell's battery, especially of those consisting of U-tubes containing in the one limb copper sulphate solution, in the other zinc sulphate solution, both being worked up into a paste by plaster of Paris, and then allowed to set in the tubes. Their use as an unit in electric measurements was examined; it was found that in some cases the difference of potential remained constant, whilst in others it decreased very rapidly. Such batteries cannot be used in electro-therapeutics.—*Jour. Chem. Soc.*

1885.

(Continued from our last issue.)

In the ordinary course of events the snowstorm of Wednesday morning would have led us to discuss once again the danger of overhead wires, but we must content ourselves with a brief reference to it here. The Telephone Company since its inception has had no storm of any magnitude to contend against, and it may be thankful that even Wednesday's visitation was less disastrous than any winter might be expected to bring. Still, its effects were such as not to increase our respect for the shrewdness or business capacity of men who persist, against all advice, in following a system, or rather want of a system, which has nothing to commend it except the obstinate consistency of a speculative directorate. It will save the shareholders thousands of pounds if the storm of Wednesday is followed by another which breaks down every telephone wire in London. The time is rapidly coming when argument will be useless, and when the property will be valueless instead of valuable. The case can be put clearly and summarily in a few sentences. The Company has a large capital, a great part of which was paid for patent rights which will expire in a few years. Up to the present very little has been done to depreciate the capital account paid for these rights. The system adopted in the work—commenced in ignorance and continued against advice—is of such a kind that periodical breakdowns are absolutely certain. While everything is new these breakdowns may not be overwhelmingly extensive or expensive, but as the years roll on—say, about the time the patent rights expire—the London atmosphere will have done its work upon the wires, and during any winter storm a general breakdown may occur. What will the shareholders do then? Investigate and find that the "powers that be" hold few shares, having judiciously "got out" at the right time. We have said it before, we say it again, that the telephone system of London is not carried out so as to be a lasting benefit to the shareholders, and, further, the public suffers considerably from the uncertainty of the system. At one time we thought the Company intended to force the hands of Government, for all discerning persons must see that sooner or later the Government must take over the telephonic business of the country. The shareholders may rest assured that if what they have to sell, after years of monopoly, is valueless, the Government authorities will say so, and proceed quietly to do the work themselves. The constant aim seems to be to consider how to keep up or to get a higher quotation for their shares—not to make a good, sound, solid, substantial business, which future years will strengthen, and which attacks or opposition from within or without cannot hurt.

The strong views we have expressed from time to time in relation to telephony are said by those who should know better to be the views expressed by the Post Office officials, or the views of opponents to the existing company. Nothing could be further from the truth. The opinions are those of wholly disinterested critics, who, seeing one of the best applications of electricity—one of the most beneficial and useful to the business community—practically undeveloped, and threatening to become a white elephant to innocent shareholders, would force a change in the right direction while yet there is time. We shall now leave this subject for the present, and continue our account of work done in the past year by individual firms, adding some expressions of opinion upon the prospects of electrical applications generally

We have already referred shortly to the work of Messrs. Siemens, who, together with the Brush Corporation and Messrs. Crompton and Co., probably do the largest share of electric lighting work. Messrs. Crompton and Co. have during the year completely altered their design of dynamo, and have substituted the Crompton type of machine for that of Bürgin in all sizes and patterns. It is hardly necessary for us here to say more than that the Crompton type is more nearly akin to the Gramme than Bürgin. This firm has been fortunate enough to keep their works fully employed, and, in fact, have been able to keep a night gang going throughout the whole of the year. During the early part of the year they finished the fitting out of the Brazilian ironclad "Aquidaban," and made six sets of search light apparatus, including engines, dynamos, projectors, &c., for the new type of sea-going torpedo boats in H.M. Navy. They also manufactured search-light apparatus for H.M. ships "Black Prince," "Shannon," "Scout," "Landrail," "Curlew," "Caroline," "Royalist," "Acorn," and three others; and also manufactured for the Admiralty twenty-eight sets of search-light apparatus for store. The firm has carried out complete installations at Sir John Fowler's house, Braemore, on the training ship "Exmouth," the Birmingham Liberal Club, for the Mersey Docks and Harbour Board, for the Meisenbach Company, for the Royal Institution, for the East and West India Dock Company, and others. They supplied dynamos and apparatus direct for the lighting of Buckingham Palace, for Lord Bute at Cardiff Castle, for Sir David Salomons, and many others. In addition to these, through their various

Digitized by Google

agents, Messrs. Bennett and Co., J. P. Fearfield, W. Hartnell, Holmes and Vaudrey, J. C. Howell, H. Lea, Muir and Mavor, &c., they supplied nearly a hundred dynamos, as well as various other apparatus, to form part of installations in different parts of the country. They have in hand, and nearly complete, a very heavy contract for the Imperial and Continental Gas Association, consisting of dynamos, steam engines, &c., for electric lighting at Vienna. They have also in hand a large contract, for the East and West India Docks Company, for the complete lighting by electricity of the new Tilbury Docks, which, when complete, should be one of the largest contracts as yet carried out. Messrs. Crompton and Co. have during the year brought out some notable improvements in the construction of search light apparatus by the use of the Carver mirror, in place of the Margin projector, hitherto employed in Her Majesty's Navy. They have also designed and are executing an order for the lighting of a lightship belonging to the Mersey Docks and Harbour Board. Such reports as these strengthen our remarks as to the gradual progress of electric lighting.

Mr. J. H. Greenhill, of Belfast, has during the year carried out six new installations, and increased the capacity of two existing ones, all in Ireland, the total of new lamps of 16 candle-power in these installations being, in round numbers, 1,000. This included a repetition order by one firm of a machine to run 500 lamps, which was built with wrought-iron magnets (all Mr. Greenhill's dynamos are now of wrought iron), which has been running since September without a hitch. There has been very little done in Ireland in arc lighting during the year, but some important contracts are to be carried out immediately. Mr. Greenhill believes the electric light is now decidedly recovering from the result of its partial collapse, and that it will go on by sure degrees, which will be all the more reliable, compared to the "hop-step-and-a-jump" progress made during the excitement of three years ago. The experience of the past year shows that the durability of the Swan lamps is immensely greater than it was before, and if they were only about half the price, it would aid in increasing electric lighting. This opinion is based on the belief that users would not object to the more frequent renewals of lamps, and they would elect to drive them at a higher candle-power, getting thereby a vastly superior style of illumination unattainable by gas. In order to save the cost of renewals, those who use the light now rather under-run the lamps, the consequence being that the degree of illumination is not to any material degree superior *in appearance* to gas. As a proof of this, Mr. Greenhill mentions a client whose shop has been lighted by incandescent lamps for two years; but scarcely attracted any attention till he decided to put in a new machine of larger capacity, and to increase the number of his lights. This was done, yet it was when he elected to over-run his lamps (each giving a light of about 25 candles) that the difference in the appearance of his shop attracted attention, and the footpath and interior of the premises were blocked with people. Although he has been over-running the Swan lamps to this extent, he has not had a lamp give way for the three weeks he has tried it.

We may here interpolate Mr. C. Lever's opinions as to the present and future prospects of electric lighting. This gentleman has not only studied the question from a theoretical point of view, but has had great practical experience, and has visited America during the past year in order to see exactly what our cousins across the Atlantic were doing. He writes as follows:—

"When shall we realise the bright prospects which the promoters of electric lighting schemes put before the public in 1882? The fact is that those 'castles in the air' have long since disappeared, and as we enter the year 1886 we are found still grappling with a new industry. That the electric lighting industry has grown no one can doubt. The increase of electric lighting installations and orders for extensions go to prove this. But, whilst the demand is on the increase, it should be remembered that the supply is still very much in excess of this demand. Unless, therefore, the general depression of trade clears away, we must expect to find more defunct electric lighting companies during the present year. Last year saw the extinction of the Hammond Company, and the electric plant which was purchased at the sale by auction now makes its appearance in a market already glutted with the apparatus of fierce competitors, and at prices for which the apparatus could not possibly be manufactured. These are gloomy prospects, and although we are told over and over again that 'every cloud has a silver lining,' it must be owned that this 'silver lining' is a long time in making its appearance.

"I see no reason to depart from my opinion expressed at this time last year, viz., that arc lighting offers the widest field for the electric light engineer. To some it may not seem so, but this opinion has been strengthened by many recent observations. It is the only light in this country that can compete with gas. Indeed, the arc light can do more, for it can afford a better light than gas light, and at a less cost. And although we cannot place an arc light in a drawing room, we can do a great deal more than we are doing with small arc lamps. In engineering works, foundries, railway stations, goods warehouses, sidings, colliery pit banks, &c., arc lighting has supplied a long felt requirement. It would be absurd to attempt to light such places by incandescent lights. There have been attempts to do this, and they have invariably resulted in failures. The lighting of a railway station on the incandescent system is madness, for the place could be lighted much cheaper by gas. Even in large picture galleries there is considerable scope for arc lighting, if the lamps are really steady, reliable, and not too powerful. A few years ago I saw a picture gallery lighted by arc lamps of 800 candle-power each, and the other day I walked into a picture gallery lighted by 20 candle-power incandescent lamps. There was no comparison between the two; in fact, I heard complaints that the incandescent lamps were so placed as to be most disagreeable to the eye, and people went away with the headache. I never experienced this in the former place, lighted by the arc lamps, and I never heard any complaints to this effect, although I must say that the arc lamps were not as steady as they ought to have been. Now, I do not for one moment infer that all picture galleries ought to be lighted by arc lamps. The incandescent light is an expensive light, but it has its sphere of usefulness. Every steamship, every flour mill, and every coal mine ought to be lighted on the incandescent system. Its safety alone is a recommendation. But there are so many instances in which the lights are misplaced—where incandescent lamps are installed instead of arc lamps, and arc lamps instead of incandescent lamps. Let me give an illustration. I know a theatre lighted by incandescent lamps. In the *sunlight* over the auditorium are about 250 lamps of about ten candles each. The machinery is big enough to light a small town, and yet it never seems to have struck the electric light contractors that one good arc lamp would require one-tenth of the power, and give the same amount of light. Of course, when our lighting supply stations are erected—when electricity is laid on as gas is at present—we shall be able to please ourselves, and have our arc lamps or incandescent lamps fixed with the same ease that we can now have our Bray, Sugg, or Thorpe and Tasker's gas burners fixed. That will be electric lighting."

Digitized by Google

We will now consider the work of a firm away from the metropolis—that of Messrs. Walker and Olliver, of Cardiff:—

In January this firm opened a branch at Newcastle-on-Tyne, and in the following June removed the Midland branch from Nottingham to Leeds. They have had the usual mining signal work in all parts of the country, but principally in the South Wales district, where the past year has seen the conversion of several of the older firms, who adhered to the old method of signalling, to the electric system. In fact there is hardly a firm of note now in the district which has not adopted electric signals, and these signals are in all cases a great boon. Some of these underground signals have circuits several miles long. This would, of course, be nothing on the surface, but it is a great deal in a mine. South and West Yorkshire and Scotland have also adopted electric signalling; but Northumberland and Durham have only partially adopted it, and Lancashire hardly at all. In many cases, suggests Mr. Walker, the adoption has been delayed by inefficient work in the first instance; cheap bells, cheap batteries, cheap wire, and when a signal breaks down managers are apt to blame the system, and not the work.

With regard to telephone work the firm has done absolutely nothing. Mr. Walker says, "The action of the United Telephone Company in blocking up all sources of supply, and in annoying every one who uses a telephone which is not paying them a royalty, has pretty well rendered this department not only unprofitable but a serious loss. Considering the delicacy of telephonic apparatus, the training necessary to enable a man to quickly repair the numerous trifling faults that are constantly occurring, even with the best apparatus, and the trouble of way-leaves, it only needed the additional spur of the merciless persecution to which we have been subjected to make us decide to have very little to do with it until the patent has expired, or until some one brings an instrument into the market that shall be as good as the Edison-Bell combination, using the term in its full legal sense, and that shall be able to hold its own legally, and whose owners shall be willing and ready to withstand all attacks, and to protect its users and agents. At present, unfortunately, this does not exist. The instruments of Prof. Silvanus Thompson, though, as far as one can judge, free of the so-called master patents, and backed by a strong company, have not, so far as our experience goes, got over the initial manufacturing difficulties that often beset a new form of apparatus. The fault in this case, in our opinion, has been in endeavouring to make the instruments too cheaply. If the profit required would not allow of more careful work, it would have been better to have added £1 or £2 to the selling price, and have put that amount extra into the construction."

In electric lighting Messrs. Walker and Olliver have been more fortunate. In April they carried out an installation of four arc and forty incandescent lamps at the New Elliot Pit, belonging to the Powell-Duffryn Steam Coal Company, of which Sir George Elliot is chairman, this being the second colliery lighted for the same company, and a third is in hand, to consist of three arc lamps and fifty incandescents. In each case both arcs and incandescents are worked from a compound shunt-wound Gramme dynamo, the arcs being in parallel circuit with the incandescents. In July an installation of seventy incandescent lamps was carried out at the Elemore Colliery, belonging to the Hetton Coal Company, this being the third contract executed for that firm. The lights are used to illuminate four seams about sixty yards apart, the dynamo and engine being in the top seam, and wires led to the others. The arching and roadways are whitewashed as far as possible, and the effect is very good indeed. The difference between walking about in one of these collieries so lighted, and a colliery lighted even with gas, is quite as great as between a country road, on a dark night, and a *gas*-lighted street. The lights are not carried into the workings, but are taken well along the main roadways for several hundred yards, and into all engine houses, stables, &c., switches being placed to turn the lamps out when not required. The dynamo and engine run day and night from early on Monday to Saturday, stopping morning and evening, as usual with all engines in collieries, for examination, when the brushes are trimmed if required. The three installations at these collieries are with old Gramme machines; that is, with the wood hub so much condemned, with which, though taking a larger density of current than Mr. Kapp and Mr. Crompton would allow, running at a higher surface speed, and for longer hours than is usual under harder conditions, there has been scarcely a hitch the whole time they have been running. Two of these dynamos are running the third and fourth winter respectively. Leaving out the convenience, the safety and the beauty of the light, the company have realised a large saving in gas fittings alone since its adoption. At the meeting of the South Wales Institute in November last, on the discussion of a paper on "Improvements in Electric Lighting," the general manager of the Powell-Duffryn Company's Collieries, who hails from Durham, stated that he had had his collieries carefully costed, where gas, oil, and electric light were used, and that though oil came out cheapest, the electric light was not far beyond it, while gas was double the latter. His conclusion was that, taking into consideration the convenience of the electric light and the amount of light obtained, it was far and away the best form of illuminant for collieries.

Recently an installation of 50 incandescent lamps has been put in one of the Babbington Collieries, near Nottingham; an installation of six arc lamps and 90 incandescent lamps at new Herrington Colliery for the Earl of Durham. These are for the surface, and are worked from one dynamo as before. An installation, consisting of thirty incandescent lamps, with provision for more, and a separate dynamo is being carried out at the same colliery underground to light the pit bottom, main roadways, stables, engine houses, &c. The dynamo and engine are placed underground, plenty of steam being available. An installation is nearly completed, consisting of eight arc lamps and forty incandescent lamps, at the Windsor slipways, Cardiff. There are two long jetties, one on each side of the double slipway, the latter being arranged to take in two ships at the same time. There are four arc lamps on each jetty, and reaching up to abreast of where the ships are when out of the water. The fitting shop, joiners' shop, engine houses, stores, &c., are all lighted by incandescent lamps, the same system being adopted as already explained. The switches for the arc lamps with this arrangement are usually placed in the engine house, but of course they can be fixed at any convenient point. The most notable feature the firm claims for the year in connection with electric lighting work consists in the adoption of a system, carefully worked out, of running arc and incandescent lamps from the same machine, a compound shunt-wound self-regulating dynamo. The arc lamp used is the old "Brockie" mechanical commutating lamp, but without its feed wire and without the revolving circuit-breaking commutator.

The lamp has a single electro magnet, and just one or two clutches, according as it is a single or double lamp, with the usual guides, &c. The wire of the electro-magnet is in the same circuit with the arc, and wired with the gauge required to take the current intended for the lamp, a matter of very simple calculation; so that lights of varying power can be used.

Digitized by Google

Thus, in a large open space a large current is used, in a confined space a small current, getting the best results all round. It is found that by cutting down the current a greater economy in carbons is obtained. Where a pair of carbons used to last six hours they now last twelve hours. In connection with this, it is advantageous to use carbons as large as possible to a certain limit, so that all the work done is inside the arc, and very little glowing carbon outside. We find that there is less liability of the carbons sticking, as they do not tend to soften so much, should they accidentally drop into contact, than where you have two or three inches of glowing carbon outside the arc.

For results, with 13mm. carbons, 6 ampere current, 35 volts across the terminals of the lamp, a light is obtained that will enable one to read a newspaper at 40 yards when the lamp is 20ft. above the ground. Both arc and incandescent lamps are perfectly steady, and the feeding of the arc lamps, no matter how many there may be, has no effect upon the light given by the incandescents. A little consideration will show that this is only as it should be, since an arc burning long, or going out by breaking circuit is merely equivalent to turning out a certain number of incandescent lamps, and an arc burning short or running into contact is equivalent to the reverse.

The rationale of the working of the arc lamp Mr. Walker suggests to be as follows:—"You start with a certain E.M.F. at terminals of machine, a certain E.M.F. at terminals of lamp, less, of course, than that at machine, a still lower E.M.F. across carbons. Now, supposing the E.M.F. at terminals of machine to remain constant, the arc increasing increases the resistance, weakens the current, and raises the E.M.F. at the arc, so that you have the two things—current weakening, tending to allow your top carbon to fall, and E.M.F. rising, giving increased power to maintain the arc. The result is a beautifully steady light, and I think the lamp can hardly be beaten for simplicity. The early arrangement gave each arc lamp two wires direct from the machine; but later a return large main for several arcs is used, giving each arc its own positive main, in which is inserted a resistance variable at will. The arrangement seems well adapted for a large number of industrial purposes, where it is of advantage to have an arc light in certain places without the trouble of a special machine; and it must certainly bear the palm for simplicity. The one feature against it is the extra length of wire used; but, in practice we do not find that serious, as by placing the dynamos in a fairly central position the actual length is much as usual, and working with smaller currents we are able to use smaller wires."

Several improvements have been made in the Gramme machine, small perhaps in themselves, but often bearing very important results in the matter of wear and tear and output. Thus modifications and alterations have been made in the pattern and construction of the brush holders and terminals, the quantity of iron in the core, and the winding of both armature and field magnets. The output has been largely increased by these modifications with ease and perfect safety.

Automatic regulators have been designed and introduced. The regulator is designed to compensate for the pulsations of a gas engine, and to replace the somewhat barbarous plan of fusible cut outs—which, by the way, often do not cut out when they ought—by throwing in either an artificial resistance, or by opening a by-path to carry off the surplus current.

A current meter has been designed to count in a simple manner, in any units that may be arranged, the product of current and E.M.F. actually expended during a given time in any place over which the meter has control.

We shall now give Mr. Walker's opinion as to the prospects of electric lighting in almost his own words. He says, with regard to the future of the electric industry generally:—"I am *very* hopeful indeed. In spite of companies breaking, and all the money that has been squandered in floating them having been wasted, electric lighting at least has been steadily advancing in a quiet unobtrusive way. Firms and individuals who some six years ago would have laughed at the idea of adopting the electric light are now, in many cases, using it, and wondering how they did without it, and many others are now convinced that there is something in it, and are determined to adopt it if they get another shilling on the coal, another pound on the iron, &c. It is very doubtful if the shilling or the pound will come; prices rarely go back; but they will have the light all the same, and for this reason. Sooner or later they will cease to look out for an advance in prices—more probably they will have to face a further reduction—and then the question comes, How is a margin to be made between cost and selling price? There is only one answer to this, and it has been given in days gone by over and over again. Wages cannot be reduced beyond a certain limit, and the only resource is increased productiveness of machinery. In this, electricity will play an important and ever-increasing part. To lessen waste is to increase production; and in many cases to give a better light is to lessen waste, or to give greater facilities for manipulating. Again, the work value of the human machine, whether it use its hands or its head, whether it be male or female, depends on the state of its health; and the state of its health is very largely dependent upon the atmosphere in which it works. How often are the seeds of consumption sown in passing out of a hot stifling room into the delightfully refreshing, but deadly cool atmosphere outside, and this no matter whether the hot room is a ball room or one of the flats of a factory? The ball room belle can lay up, while illness to the poor factory girl means privation, if not starvation. How many broken threads, spoilt stockings, spoilt curtains, wasted yarns, &c., are due to colds caught in this way; and how many would be avoided if factories were lighted with incandescent lamps, which can be taken inside the most delicate fabrics without injury, and that show all the colours true as they are by daylight. And how many ruined eyes may we place at the door of flickering gas and vitiated atmosphere? Again, are not arc lamps distributed down back streets and in dark lanes better than policemen?

"But that is only one branch, though an enormous one. I have a firm belief that it is as certain as anything can be in this world that the electric light will supersede gas for illuminating purposes. It has many difficulties, and it will take time, but it is sure to come. Gas, which even at this day, if we examine it dispassionately, is really a barbarous method of illumination, was looked upon as the invention of a madman when it first came out. Once have the electric light in house or factory, so that it is as reliable as gas, and the user would never go back. Gas superseded candles and the old oil lamp, not because it was cheaper—it is not by a very long way—but because it is more convenient, certain, and far safer.

"In my opinion, it would be well for the electric lighting companies of the future to commence in a small way, and work up. They will always be able to get capital if they can show dividends. Then as to the future of electrical engineers, I see no reason to be depressed in this matter. At the present time, no doubt, there are many who have been employed in electrical work who are seeking work; but are they all *bonâ fide* electrical engineers? Are not many of them men who have gravitated into electrical work because a few years ago high salaries were paid, or because they thought electrical work was easier and more

Digitized by Google

genteel than work they were doing? I believe myself that the demand for trained electrical engineers must soon increase, to keep pace with the requirements of the rapid advances that are being made; and I should be very sorry to say a word against men already skilled in one profession gravitating into ours. The union of mechanical and electrical engineering, or of chemistry and electrical engineering, must be of great advantage to the profession finally adopted, provided the latter be honestly, carefully, and patiently studied and practised. Unless this is done, the so-called electrical engineer will do harm and bring the profession into contempt by the blunders made. It appears that there is too great a tendency to think, as a local ironmonger told me, that 'there is no mystery about electrical engineering.' A man who has purchased a bell and battery and a few yards of wire at a shop, and has succeeded in getting them to work, and who, perhaps, has a few crude ideas on the subject, straightway dubs himself an electrical engineer, and will take a contract to execute anything, or will offer himself for any kind of work, under the impression that he is quite sure he can do it if he tries. There is only one way to acquire a sound practical knowledge of electrical work, as of anything else; and that is by years of careful study, backed up by actual practice, actually doing the work. No school or college course of a few months, however well appointed the school or the college may be, can ever be more than preparatory to practical work. It is undoubtedly a valuable preparation, but no more; and young fellows whose means will allow it would do well, after passing through these schools to article themselves to some good firm where they can acquire the necessary manipulative experience. Another point may be suggested. Is the work developed enough to divide electrical engineering into separate branches, and to have telegraph, telephone, electric light, &c., engineers trained in their own particular division, and knowing little of any other? I would most strongly advise young fellows who aspire to become electrical engineers, to train in all branches, and to lose no opportunity of studying or practising all branches of the subject. They will find that the broader the basis of their knowledge of the subject, the greater the mastery of each part of it, and the more valuable to the individual. Moreover, in electrical work, one can never tell what is coming next, and an exclusive training in one branch is a great drawback, should one be thrown accidentally or temporarily into contact with another branch. Telephone work, for instance, necessitates the training of the mind to grasp the idea of very minute currents, and the whole of the apparatus in connection with it is small and delicate. A small particle of dust interposed between two surfaces in contact or a layer of lacquer, and the instrument is out of order. On the other hand, in electric lighting the opposite conditions hold good. Here we have large currents, high E.M.F.'s, and many H.P.'s transmitted. A mastery of both materially assists one in discovering faults in either, but a training exclusively in one almost unfits a man for work in the other. The man who has spent his time solely in electric light work cannot appreciate the delicacy of telegraph and telephone work; and I have found the greatest difficulty in getting a highly-trained mechanic who had been accustomed to submarine work into electric light work. For a long time the tendency is to put delicate springs where perhaps half-inch brass was required.

"The advice given to all desirous of entering the profession is, learn to do, as well as to tell others to do; be able to use hands and brains; and regrets will never arise from such a state of things. Suppose, for instance, a telephone is out of order, the company is written to, and an inspector arrives. If the fault is a trifling one, as it very frequently is, it would be to his own interest, to that of the user and his employer, to put it right there and then. A dirty connection wants cleaning, a screw out of regulation, a drop of water in the battery, and so on. If, however, he appears in kid gloves, with a very delicate instrument, perhaps measures various resistances, and ends by sending someone else, there is delay and expense, and, if it occurs frequently, annoyance all round.

"This bears on what I am about to say as to the field for electrical engineers in the future. Irrespective of companies and firms manufacturing electrical apparatus, or selling electricity in one form or another, as the large industrial firms gradually adopt one kind of apparatus after another, they will be obliged to have their own electrical engineer, who will be an important man about the works. Every firm of any standing now has its mechanical engineer, who has charge of all the machinery, superintends the erection of new plant, &c. Many firms have now also an electrical *man* of their own. In most cases, at present, he is a working man, because the apparatus used is not of sufficient extent to warrant paying much for looking after it, and for designing or for advice in purchasing. This man is usually well paid, and has a fairly easy time, provided that he keeps things going. As time goes on, however, there will be more and more cases where he, having done his best, is beaten simply because the work is beyond his knowledge, he having only what is known as rule of thumb knowledge; hence, a professional electrical engineer must be called in. Ultimately the temporary assistance becomes permanent. His position, and his advancement will depend upon things going well. Managers and owners meet and confer together. 'How does your electrical engineer go on?' 'Oh, very well; we never know what a break down is since he came, and if we want to make any alteration or to put up any new apparatus, all I have to do is to tell him what I want. He brings me the order to sign, or gives his estimate, and that is all I know till I see the thing working. If anything goes wrong he's there quickly.' I think it may be safely prophesied that if this man wants a rise of salary, as the work increases, he will get it.' 'And how does he keep things going so well?' 'He examines everything himself personally every now and then; and if he is at a particular place, and sees some little thing, say a wire loose or dirty, a dirty terminal, &c., he does not sit down and make a long report, he takes out his knife and cleans it, or screws the wire up.' But, on the other hand, suppose it is this which the manager replies:—'Oh! he seems very clever, and can talk very well, but I am afraid we shall not be able to keep him, he is so expensive.'

"There is an important branch of electrical engineering at present almost untouched—viz., transmission of power. How easily, and how quickly, and with how little occasion for repairs, can two cables be laid, in almost any position, for mines, ironworks, docks, factories, as compared with shafting, ropes, steam pipes, compressed air. I have every confidence that the day will come when shafting and belts in factories will be looked upon as a barbarism, and people will wonder however they endured it so long. Numerous cases will occur to every one where cheapness and facility of working would result from the adoption of electric transmission. You have a ship in the dry dock, and want to drill a hole in her side; take a couple of wires down, a few minutes' work, and attach them to a motor that a man, or at most two, if the work be large, can carry. It may be objected that all I have said applies to the future. A good deal does, but not all, and in this work the future of to-day is the present of to-morrow. Ten years ago I was laughed at for proposing electric signals in mines; to-day the system is almost universal in cer-

Digitized by Google

tain districts. Ten years ago there were absolutely no electric lights in practical use in England, except that in Dungeness Lighthouse; now look around you. Ten years ago there were few electric bells used—they were appreciated, but found to be always out of order; now they are the rule, and are rarely out of order. There is only one branch in which the hand has gone back, and that only for a time. Perhaps the greatest injury which the United Telephone Company have done, by the use they have made of their monopoly, is in stifling all improvement; and a second in shutting the door of an important branch of the science to the coming electrical youth. If the telephone were free, there is no other branch that would confer a greater boon on society at large, on manufacturers, and on electrical engineers, nor that would receive more rapid development and improvement. It is to the discovery of the telephone mainly that we owe the great and rapid development since 1877. To those whose heart is in the work I would say, in conclusion, master your subject, take every opportunity of studying and practising it, and for the rest, go on and fear not."

CORRESPONDENCE.

THE TRANSMISSION OF POWER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I read in the last number of your esteemed journal a small paragraph which I cannot allow to pass without protest.

The writer of this paragraph makes me say that:—"To M. Marcel Deprez must be given the honour of being the pioneer in the application of electricity for this purpose" (transmission of power). If you will look carefully through all the numbers of *l'Electricien* published during the last two months, and particularly that of the 26th December, 1885, you will be convinced of the mistake made by your contributor.

I have said quite the contrary to the above, and have shown by means of figures and dates that M. Marcel Deprez comes in a good last, with machines which are the heaviest known at the present moment, and which, for a given power, show the greatest expenditure in excitation (18 per cent.)

I hope you will be kind enough to insert this notification in your next issue.—Yours, &c., E. HOSPITALIER.

6, Rue de Bellay, Paris, January 2nd, 1886.

NITRATE IN BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is the solution generally used in nitrate of soda batteries:—

1. Water 7oz., soda 3, sulphuric acid 2oz.
2. The acid is generally added to the solution of nitrate.
3. I should not advise the use of bichromate of potash, as it increases the cost of working, and in my hands gives no better results.—Yours, &c., L. L.

81, Avenue-road, N.W.

AN ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Apart from the quaint way in which the subject is written up, there is nothing new in the *Daily Telegraph* account of the Electric Boy. It is well known in America and other dry climates that the friction of the soles of the feet on a carpet, even the act of quickly pulling off silk stockings from the leg, may generate enough electricity to produce sparks, sufficient, I believe, to light a gas jet. The hard horny foot of the negro, like the skin of the cat, is specially adapted to this purpose; and your correspondent incidentally names the carpet and the bare feet. Prof. Dewar's experiment with the galvanometer is of entirely different nature. It is originally due, I think, to Dubois Reymond; certainly it is given, with a large woodcut, in a manual of physics over twenty years old. I myself demonstrated it before the Physical Society in their first session, now many years ago. The deflection caused by contracting muscle is not easy to explain. Probably it is thermo-electrical; certainly it is purely adventitious, and not connected in any way with nerve force, or physiological currents.—Yours, &c., WILLIAM H. STONE.

DYNAMO TESTS.

(Continued from page 158.)

METHODS OF MEASUREMENT.

Measurement of Resistance.—For the standard resistance, a ten B. A. unit coil by Elliott, which had been compared at the Cavendish laboratory, and was used by Prof. Rowland in his recent determination of the ohm, was employed. The values of the resistances in terms of this coil were reduced to the Paris ohm, by dividing by 1·0112.

The bridge used in the comparisons was built at the Univerity Workshops, Cambridge, England. Its fixed (equal) arms were connected by a platinum silver wire bent in a circle, and their ratio changed by making contact with the galvanometer circuit at different points on the wire. Beside the wire was a scale, and on the arm carrying the galvanometer contact, a vernier reading to tenths of a division. When the fixed coils were each one ohm, a whole division of the scale meant a change of one part in 10,000 of the ratio, while with the galvanometer used, a change of one-tenth of a division or one part in 100,000 could be detected. The bridge had been calibrated for use in the determination of the ohm. With fixed coils of one ohm, the range of the instrument was about 10 per cent., so the resistances to be compared were always approximately equal. The different coils to be compared were balanced against resistances taken from "comparators," designed by Prof. Rowland. Each of these consists of ten coils of equal resistance wound together on a copper cylinder, the whole being coated with wax or paraffin and put inside a larger cylinder, the space between being filled with feathers. At the top the cylinders are separated by an annular sheet of hard rubber, around which two circles of ten holes each are bored for the terminals. The ends of each coil are taken to copper blocks screwed firmly beneath opposite holes in the two circles. The tops of the copper blocks are thoroughly amalgamated and the holes partly filled with mercury, connections being made by short U-shaped copper rods. Three comparators of 10, 100, and 1,000 ohms were used, giving a range of from one to 10,000 ohms. Each coil of the 10-ohm comparator was balanced directly against the 10-ohm standard, then the ten coils in series were balanced against each of the 100-ohm coils, and finally the 100-ohm comparator in series compared with each of the 1,000-ohm coils. In the measurements, the inner cylinders of the comparators were filled with water, and the standard immersed in water, the temperatures being noted. The zero of the bridge scale was taken as the mean of the readings when the resistances being measured were reversed. In measuring the resistance boxes, they were kept for six or eight hours in a room whose temperature was nearly constant, and then balanced against corresponding resistances taken from the comparators, the temperatures being, of course, noted. The coil for potential measurement was immersed in turpentine, its temperature recorded, and its resistance measured as above. The resistances compared at the Johns Hopkins University were the box for current measurements, the coils and bridge for measuring resistance, and the coil for potential measurement.

Measurement of Potential.

The galvanometer used for potential measurements was by Hartman. It was furnished with a Siemens bell magnet, closely surrounded by a solid copper block, and damped very readily, only making two or three swings before coming to rest. The

Digitized by Google

suspension was a silk fibre about fifteen centimetres long. The coils, specially wound over the regular winding of the instrument, had a resistance of about two ohms. The galvanometer was in a circuit with resistances that were varied from 1,000 to 150,000 ohms, taken from boxes, two of 100,000, one of 10,000 ohms, the former by Elliott and Breguet, the latter by Bergman. All calibrations being made with the (30,000 + 20,000) Elliott coils in the circuit, it was necessary to compare the other resistances with these coils. The arms of the bridge being made equal, the (30,000 + 20,000) and (40,000 + 10,000) Elliott coils were balanced in succession against the 50,000 Breguet, resistances being added to one or the other until there was no deflection of the galvanometer. It was found that

50,000 Breguet = (30,000 + 20,000 + 280) Elliott.

50,000 Breguet = (40,000 + 10,000 + 250) Elliott.

The (30,000 + 20,000) ohms Elliott was also measured in terms of the bridge coils, and the value found, 49,960, was so nearly correct that in getting the ratios of the 1,000 and 2,000 ohms Bergman—used in measuring armature resistance—to the (30,000 + 20,000) coils, it was assumed that their values in terms of the bridge coils were the same as if measured in terms of the (30,000 + 20,000) ohms. The deflections were read by a telescope and scale, the latter by Browne and Sharpe, graduated to centimetres and millimetres. The distance from the telescope to the mirror was two and one-half metres.

Calibrations.—The galvanometer was calibrated, both by measuring a current passing through a standard resistance at whose terminals the leads of the instrument were connected, and by the difference of potential at the terminals of a calorimeter. The constant was also checked with that of the current galvanometer, after each test, by measuring the current through the German silver strips used for the external circuit of the dynamos, and the potential at their extremities. During the tests forty calibrations were made, thirty-six with the silver voltameter and standard coil, and four with the calorimeter. The constants determined by the calorimeter agreed so closely with the measurements by the voltameter, and the labour both of observation and calculation in the former was so much greater than in the latter, that it was thought unnecessary to make the observation any oftener.

Voltameter Calibrations.—The current used varied from one to one and one-half ampere, giving a difference of potential at the terminals of the standard coils of from twenty to thirty volts. The coil shown in Fig. 2 was of No. 22 German silver wire, wound on glass rods fixed in a wooden framework. The turns were kept apart by silk cord wound on the rods. The whole was immersed in a high grade oil (300° fire test) kindly furnished by the Standard Oil Company. The oil was constantly stirred while the current was passing. The measurement of the resistance has been described. Its value was 21·161 ohms, at 14° C. For measuring the currents, a silver voltameter was used, the anode being a spiral of silver wire wrapped in filter paper, the cathode a platinum crucible filled with a 40 per cent. solution of silver nitrate. The calibrations took from ten to twenty minutes, the deposit ranging from ·9 gram to 2· grams. The times were noted by a chronometer whose rate, + 1 second per day, was neglected. When the experiment was finished, the solution was poured out of the crucible; the deposit first washed with distilled water, then allowed to soak from one half hour to twelve hours, then washed again until there was no precipitate with a solution of sodium chloride, and finally slowly dried and then weighed. A double reading of the galvanometer was taken each minute, and the constant calculated from the mean reading for the time of observation. The constant is given by

$$k_{50} = \frac{C\,R\,(1+M_c)\,(t_c - 14°)}{2d} \left\{ 1 - M_b\,(t_b - 25°) \right\}$$

where

k_{50} = constant for (30,000 + 20,000) ohms;
R = resistance of standard coil at 14°;
t_c = temperature of standard coil;
M_c = temperature coefficient of standard coil;
M_b = temperature coefficient of box;
t_b = temperature of box;
$2d$ = double deflection of galvanometer;

25° being taken as the standard temperature of the box.

When other resistances were used in the circuit, the constant was multiplied by their ratio to the (30,000 + 20,000) ohms.

(To be continued.)

MAGNETISM.

BY WILLOUGHBY SMITH.

(Continued from page 149.)

If the iron rod be placed parallel with the earth's magnetic lines of force, it will become magnetised in the direction of its length, but if placed at right angles to these lines it becomes magnetised in the direction of its width; or, in other words, a magnetisable body becomes magnetised by induction from the polarised lines of the earth's magnetism in a direction parallel to those lines. The value for any particular position remains constant, so that, whenever the rod is placed in the same position, the same value is obtained, provided the rod has not been subjected to any mechanical agitation. It therefore follows that the magnetism induced in the rod may be varied or reversed by simply altering its position in relation to the earth's magnetic polarised lines. A few moments' thought and reasoning on the nature and results of this experiment may not be altogether without instruction.

Consider that a length of magnetised iron or steel of any form will, if at liberty to do so, always rest in a position symmetrical to the polarised lines of magnetic force emanating from the earth or from any other source. If, however, there are two sources of magnetic polarisation acting at the same time, then the iron or steel will take up a mean position. The iron and steel emit their own polarised lines of force, which, more or less, affect each other, endeavouring so to move the masses of metal from which they proceed as to permit of the lines of force emanating therefrom being, as nearly as possible, symmetrical to each other, and then all apparent influence ceases. In the case of the small magnet, freely suspended in the neighbourhood of the polarised rod of charcoal iron in the experiment before described, the rod of iron and the small magnet both sent forth their own lines of polarisation, causing the relative position of the two bodies to be so altered as to allow the magnetic lines of force emanating therefrom being symmetrical to each other, or, at least, as nearly so as the interfering earth's magnetic field permitted them to be. In this case it is only the magnet that moves, the rod being, for all practical purposes, a fixture. It follows that what is taking place when the iron rod is moved in the vicinity of the magnet in the manner before described is, that as the rod is moved the lines of force proceeding therefrom are also moved; consequently the position of the lines relatively to those produced by the magnet is changed, and the latter, being free to move, is influenced by its own lines of force, which change their position until they again become symmetrical to those of the rod, and thus the deflection of the magnet is caused. It has long been known that a magnetic needle, if suspended so as to be movable only in the vertical plane, will remain in a *horizontal* position at the magnetic equator; but, if gradually moved from that position either in a north or south direction, it will assume every degree of inclination until it reaches the magnetic pole, and there it will take up a *vertical* position. This is called the magnetic dip, and, as far as I know, no satisfactory explanation has been given to account for the phenomenon; but I consider it a beautiful illustration of the correctness of the hypothesis which I have above ventured to put forth.

In Diagram IV. I have endeavoured to better illustrate these lines of force and their effect on each other, as my imagination represents them. A, B, and C, show the positions assumed by the magnet in relation to the influence of the lines given out by the iron rod. As I imagine it, each atom contained in the rod of iron has its own polarising effect, consequently each atom forming the surface of the rod affects the atoms of the medium surrounding it, and, that being so, how inadequate must be the representation of those lines, which in reality must be more numerous than the most sensitive human imagination can conceive; in fact, the phrase "lines of force" is a mere figure of speech, used for the purpose of clearly indicating the direction of polarisation.

Dr. Gilbert, to whom I have already referred, was the first to discover, or at any rate to publish, the interesting fact, that the intensity of a magnet is altered when the iron or steel is affected by any mechanical percussion. To illustrate this, let the iron rod,

Digitized by Google

as used in the last experiment, be in such a relative position to the magnet as to cause a certain deflection, it being understood that the rod is magnetised simply by reason of its position in the earth's magnetic field; and, while in that position, north and south, let one end of the rod receive a blow from any mechanical contrivance; the deflection will be then increased, and will continue to increase after each blow up to a certain point, after which no mechanical influence appears to affect its magnetism. In an actual experiment the maximum deflection was reached at the fifth blow, and the ratio between the maximum and minimum deflection was as 1 to 2·34; for instance, with the rod in a horizontal position, north and south, the deflection was 23·5, and after the fifth blow it was 55·, or 2·34 times the amount. On another occasion when the rod was in a vertical position the deflection was 64 divisions, and after the fifth blow 150 divisions, which is, as in the previous case, 2·34 times the original amount; the ratio of increase varies, however, with each specimen of iron, and depends upon its purity and dimensions.

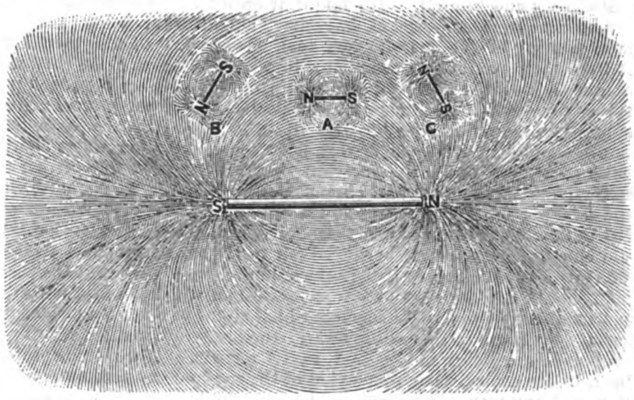

DIAGRAM IV.

The magnetism is not only increased by mechanical percussion, but the increase is to a great extent permanent whilst the rod remains undisturbed; but if its position be changed and it is again subjected to mechanical percussion, the previous magnetism will disappear and a fresh maximum value will be obtained, which is the maximum value of the new position. Mechanical percussion

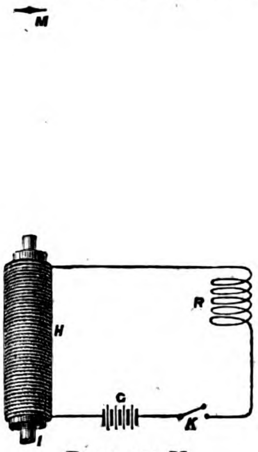

DIAGRAM V.

appears to affect more or less magnetism, developed in any known form; but, to arrive at definite and positive conclusions, a series of long and well-devised experiments must be conducted with extraordinary care and patience, as there exists such a variety of circumstances, each one of which, if neglected or overlooked, might vitiate the correctness of the results. The following experiment was made in electro-magnetism. A bar of round charcoal iron ·25in. in diameter, and 12in. in length, was annealed by being raised to a red heat and then allowed to remain undisturbed until the fire had died out and the bar become cold. Over a brass tube, ·31in. internal diameter and 10·5in. in length, was wound 520 turns of silk-covered copper wire, the total resistance of which was ·72 ohm. This helix was joined in circuit with a battery, a resistance and a key, as shown in Diagram V. H represents the helix and brass tube, I the iron rod, R a resistance which could be varied as required, G one Grove cell with an electromotive force at commencement of experiment of 1·92 volt, and resistance of ·23 of an ohm, K an arrangement for making or breaking the circuit, and M the small mirror reflecting magnet. The resistance R was at first adjusted so that the intensity of the current passing through the helix alone was only ·0019 of an ampere. The lines of force given out by the helix under these conditions, and their effect on those emanating from the magnet M were then noted. The circuit was then broken at K, and the iron rod inserted in the helix by placing it in the brass tube. The rod was placed at right angles to the magnetic meridian, for, in that position it was not sufficiently influenced by the earth's polarised lines of force to affect the magnet M. The circuit was then again made, and the deflection of M was as given in column A, Table I. While the current was flowing

the lower end of the rod was repeatedly struck until the maximum deflection of M was obtained, which is given in column B, of the same table. After each experiment the iron rod was demagnetised, and the deflection caused by the helix alone for each current deducted from the values given. The current was then increased and the experiment repeated and so on, the results being all recorded in the table. The energy of the mechanical percussion necessary to increase the value in column A to that given in column B increases with the intensity of the current flowing, and therefore with the intensity of the magnetism induced in the rod; and it will be seen by reference to the table that the greatest increase due to mechanical agitation is obtained when the bar is only very feebly magnetised. If the generally accepted theory be correct, a rod of iron becomes magnetised in proportion to the intensity of the magnetic field in which it is placed, unless it be near the point of saturation, and, as the magnetic intensity is proportional to the current flowing through the helix, it follows that the rod should become magnetised in proportion to the current flowing; in other words, ten times the current should produce ten times the magnetism. The values given in column B approach closely to that law, except when the rod is near saturation, but not so the values in column A. It may be assumed, I think, that the values in column B are the more correct; and that with low magnetising power, mechanical percussion is necessary for the production of the true amount of magnetism corresponding to the inducing power.

I have already pointed out that it is necessary to observe great caution in manipulation, to avoid arriving at false conclusions while endeavouring to ascertain the existence, and true direction, of the lines of magnetic force of a body while under the influence of the earth's polarised lines of magnetic force; and this precaution applies, even more forcibly, when making similar experiments with an iron ring or disc. A rod of best charcoal iron ·25in. in diameter was welded into a ring 3·8in. external diameter and made red hot, and while in that state was laid on a sheet of asbestos and slowly revolved in a horizontal plane until cool. This mode of cooling was necessary, for experience had taught that if the ring remained stationary while cooling, slight, but fixed polarity manifested itself at the parts of the ring facing north and south, but that if it were revolved, as mentioned, whilst cooling no fixed polarity was manifested; therefore, when the ring was placed horizontally, so that the small magnet was in a direct line with the centre of the ring, no deflection of the magnet occurred, and although

Digitized by Google

the ring was revolved while maintaining the same relative position to the magnet, still no deflection could be observed. It might be assumed from this that no line of force were being given off by the ring, but a little thought on the subject will, I think, prove such an assumption to be incorrect. The polarised lines of the earth's magnetism affect the polarised atoms of the iron ring in their own direction, north and south; consequently the lines given out by the ring are symmetrical with those emanating from the small magnet, and, as I have already shown in the case of the iron rod, no apparent effect is developed, and it therefore follows that this condition would not be altered by revolving the ring, for, as it possesses no fixed polarity, the poles would be continually in

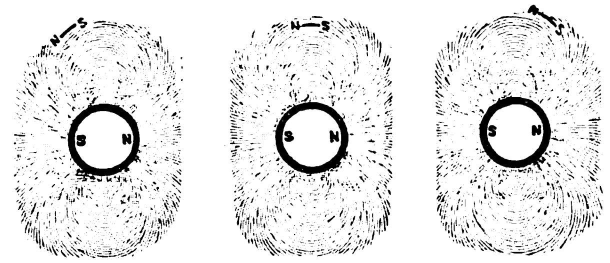

Diagram VI.

the parts facing north and south. But if either side of the ring be brought in line with the centre of the magnet, then the positions of the polarised lines relatively to those of the magnet are altered, and, as already explained, the magnet is deflected as illustrated in Diagram IV. A plate of iron, circular or of any other form, behaves in this respect precisely in the same way as the ring. The magnetic intensity in either case is increased, and definite polarity defined by a slight blow; even the flick of the finger is sufficient to produce an effect. Increase of temperature produces precisely the same results as a blow from any mechanical means. May we not, therefore, say that what we designate heat is the cause in each case, for it is well known that a few well-directed blows on a rod of iron will considerably increase its temperature?

It was thought that perhaps more accurate results would be obtained if the influence of the earth's polarised lines of force could be eliminated as regards the measuring magnet; therefore, a glass tube 20in. long and 2in. internal diameter was fixed in a wooden base B, Diagram VII.; C is a wooden cap fitted in the top of the

Diagram VII.

tube. By means of a glass hook fixed in the centre of the cap was suspended, by a very fine silk fibre, the two small magnets marked S—N, N—S, which were rigidly connected by a fine glass rod, R. The intensity of the magnetism in each was such that the couple was apparently unaffected by the earth's magnetism. A rod of charcoal iron 10in. by ·3in. diameter was annealed by being heated to redness in a forge fire, and there allowed to remain until the fire died out, and the rod became comparatively cold; it was then supported horizontally on glass, and placed due north and south in such a position as to be in a direct line with the lowest magnet. Then by moving the astatic arrangement into different positions while the rod remained stationary, the directions assumed by the magnets indicated the direction of the magnetic lines of force emanating from the iron rod. In experiments with this kind of measuring instrument great care must be taken not to place the magnets too far from the iron, because the low intensity of the magnetism induced in the iron by the earth's polarised lines of force is then insufficient to fully overcome the very slight torsion of the silk fibre, or the absence of absolute uniformity of magnetic tension in the small magnets. On the other hand, if the magnets be placed too close to the iron, it will be found that they induce magnetism into the iron, and, consequently, interfere with the results. It will therefore be understood why very careful adjustments are necessary before reliable data can be obtained.

(To be continued.)

THE ANGLO-AMERICAN TELEGRAPH COMPANY.

A meeting of shareholders in this Company, convened by the provisional committee of the shareholders' association, was held on the 5th inst. at the Cannon-street Hotel.

On the motion of Mr. John Newton, seconded by Mr. Griffith, Mr. Thomas Smith, of York, was voted to the chair.

The Chairman said he supposed they had all received a circular from Mr. Stockdale and himself. He might at once tell the shareholders that the committee were self-elected, but they thought that before the next general meeting of the shareholders took place, they should themselves elect from their own body a committee to represent them. As they were aware, at the usual meetings of the Company any single person who proposed any resolution was merely pooh-poohed. Where, however, there was unity, there was strength. He did not know whether or not the committee had done any good service, but after working for twelve months he might say that, under the pressure they had brought to bear on the Directors, the latter, although they had said, like the fickle lady, they would ne'er consent, had consented to reduce the amount they had hitherto added to the renewal fund by £50,000. At the end of the half year that fund would amount, if the directors carried out their present proposal, to about £850,000. They considered that it was absolutely necessary that the shareholders should now take some steps to prevent any further addition to that sum, with the exception of the increase which might be made by the accruing interest. As many of them were aware, there was quite sufficient to pay for two cables, which could be laid in 12 months. If anything should happen to the cables, their proportion of the receipts was not stopped for a year, and any men of business, he had no doubt, would lay a cable if necessary within that time. This association was formed last February after the meeting. Perhaps they were aware that he brought forward a motion at the last meeting to the effect that no further addition to the so-called renewal fund should be made with the exception of the accruing interest. The fund then stood at about £750,000. If the idea he then suggested had been carried out there would have been a renewal fund of that amount, and they would have been able to pay something like 3½ or 4 per cent.; but Lord Monck did not think that that was a proper thing to do, and carried out his original idea of adding £150,000 to the renewal fund, though his lordship had since modified that view, and added only £100,000. After the meeting in February Mr. Stockdale called upon him and asked him if he would join an association, and he consented. Mr. Stockdale, Mr. Jackson, Mr. Brown, and himself formed an association themselves, and they had addressed the whole of the shareholders of the Company—no small matter, as they would understand when he told them that there were between 5,000 and 6,000 shareholders. They had addressed the shareholders three times, and he was very glad to say that they had had some very agreeable responses and encouraging remarks from a great many of the shareholders, telling them how glad the writers were that the committee were taking up the question, and hoping that they would pursue the matter to the end. They had now come to a period when they thought they should ask the shareholders to help them and form a committee from among themselves. Any gentleman holding £5,000 stock of any kind would be eligible to act on the committee. He then detailed the amount of work done by the committee, and the expenses which had been incurred. The expense of copying the register was £2. 9s., but it was done by the voluntary labour of Mr. Brown, Mr. Jackson, and Mr. Stockdale. Altogether the amount expended had been £34. 18s. 8d., and they had received £20. 12s. 6d. There was therefore a balance due to Mr. Stockdale of £14. 6s. 2d. In order to provide the necessary expenses which would be incurred, they thought there ought to be a *pro rata* contribution of 1s. per cent. levied on the holdings of the members of the association, with the reservation that the minimum contribution should be 5s. and the maximum £5. They had only that morning received a very encouraging letter from a gentleman at Bury in support of the views of the committee, and urging them to push their association to the front, and "go in for a thorough reconstruction of the Company." The motion he would now propose would be to the effect that the meeting should assist the committee in the election of a committee, the present committee being only provisional.

Mr. Jackson, in seconding the motion, said that the provisional committee represented, with the support they had already received from shareholders, about £1,000,000 of the stock of the Company. The result of their action was already known to the shareholders in a dividend, though a very small one; but the dividend would have disappeared altogether had not the Directors been called to account. He said "called to account" because, as was stated at the last general meeting by a gentleman of some erudition in the law, the Articles of Association were so drawn up that they appeared to have been drawn up for the protection of the Board of Directors. That, however, was accounted for by the fact known to the original shareholders—that the Company was originally a company of capitalists, who subscribed among themselves £600,000 to a desperate concern, when the two first cables were abandoned. The 1865 cable was broken, and the 1858 cable was entirely lost. The case was desperate. There was a sort of national aspiration that there should be

Digitized by Google

an Atlantic cable, and certain great capitalists in London met, and in two hours raised the sum he had named. They took care in the Articles of Association first of all to protect themselves; but perhaps the shareholders were not aware that those articles constituted the Articles of Association of the present Company—not representing the capitalists who had subscribed the money, and were bound to secure their own interests, but a Board of Directors who represented a very small amount of capital indeed. In fact, the four shareholders forming the provisional committee held a much larger amount than the whole of the Board; and the number of the shareholders had grown from a few gentlemen to some 5,500 members. Yet the same Articles of Association stood against the shareholders, and gave the Board of Directors an autocracy, an almost irresponsible power; and he felt that this fact only required to be pointed out, when such a state of things would not last. The shareholders were co-partners in the concern, and if they did not look after their own business, but left everything to their servants (and the Directors had themselves stated that they were the servants of the shareholders), they would deserve to go without their dividends. The original founders of the Company obtained 25 per cent. per annum for the loan of their money, for they would not become a cable company at the first. Their contract was 25 per cent. interest, and 100 per cent. redemption money, and they handed their undertaking over to the original Company. Those gentlemen had received a very excellent return on their investment. The position, however, was now altogether altered. He mentioned these facts to show that it was necessary on the part of the shareholders themselves to wake up to a sense of their true position. The Company was now in such a position that whatever circumstances might arise, beyond putting competition aside, there did not seem any need for anything like the huge amount forming the renewal fund. In 1872, when the 1865 and 1866 cables constituted their property, and there was a prospect of their being lost—and they were lost and abandoned—they did not put more than £65,000 a year to the renewal fund. Now, however, they had a fund representing at least two deep sea cables, and with the interest of £30,000 a year which the investment forming that fund earned, it would soon amount to £1,000,000. Mr. Cyrus Field, too, had given them the most satisfactory assurances as to their position, and he did not suppose there was a better judge living as to the value of their property. Under these circumstances, with four good cables—so good that while all the new cables which pooled with them were broken, the Anglo-American Company's cables for months carried the whole of the Atlantic traffic—there was ample evidence that they did not require any more renewal fund. The simple issue was to stop the drain on their resources which the renewal fund had hitherto caused, letting it now for the future accumulate by the interest it earned, and to give the shareholders the net earnings, to which they were entitled. If the shareholders approved of those views let them support the provisional committee, who desired to serve the general body of the shareholders—preferred, ordinary, and deferred—who would insist on justice being done. They would succeed if only the shareholders supported them by purse and person, though the cost would not be very much.

Mr. PRUST said he desired to thank the committee warmly for what they had done, but he could not agree entirely with their views. He had sustained a serious loss in the Company, but seeing they had a renewal fund of £800,000, he thought, as he said at the last meeting, that it should be allowed to mount up to a round sum of £1,000,000. No speculators could take it away from them, and they would place themselves in a better position. In saying that he would add that for four years he had received no interest on the deferred shares he held, for which he gave 36, while that day they were only 10. The renewal fund had been formed entirely by money which would have gone to the deferred and the ordinary stockholders had it been distributed; and supposing that the company were liquidated now, the money at the credit of the renewal fund would return to those from whom it had been kept. Much as he appreciated what the committee had done, he therefore held that the best course was to let the renewal fund go on increasing to £1,000,000, especially as it was to be remembered that he got a motion carried at the last meeting, and agreed to by the Directors, that they would never use 6d. of that fund for a new cable without the sanction of a meeting of the shareholders [no, no]. There were eight cables in the pool, but with the contraction of commerce between this country and America, they had not been doing much business, and there was no necessity for another cable. He was prepared to support an alteration of the Articles of Association; and the way in which the Directors acted in issuing proxies, and so spending hundreds of pounds in their own interest, and against the shareholders, in order that they might be able to stand a consolidated force opposing the shareholders at the meetings, was much to be condemned. He trusted that some eminent lawyer or other gentleman who had been returned to Parliament would bring this matter before the Legislature, and expose the iniquitous course pursued by Directors in connection with the proxy system.

Mr. GARDNER asked whether the Articles of Association of the Company could be altered so as to authorise the purchase of their own stock, and so reduce the capital. If so, it seemed to him that that would satisfy all classes of shareholders.

The CHAIRMAN: It would require an Act of Parliament to do that.

Mr. JOHN NEWTON stated that, having been a shareholder for many years, he had seen the gross iniquity of the Articles of Association, and suggested their remedy years ago. He thought it would be a great service to the Company and all telegraph companies if they directed their attention to altering the Articles of Association and dealing with the question of the proxies. He suggested that the report of the Directors should be met with an amendment opposing the item of expense on the proxies. They could not do more until the Articles of Association were altered. It should be their policy to get an adverse division against the Directors at every meeting, and he did not think they could continue indefinitely to hold their positions if that course were followed. They could not move a resolution on any business at the general meetings unless notice had been given to the Directors and the notice had appeared in the official advertisement calling the meeting; but the Directors could checkmate the shareholders by excluding from the advertisement the very notice which the shareholder had sent them. The proper course, therefore, was to get the holders of £50,000 or £60,000 of the stock to ask for a special meeting. That was what the very same body of gentlemen had told him in the Eastern Telegraph Company. Some of them might remember that he drew attention to the Articles of Association as to the election of Directors; and if they read those articles they would find that it was utterly impossible for the shareholders to elect a Director; for this reason, that the gentleman who proposed to be elected must himself give notice some three months before the meeting, and state that he was going to put himself forward for the position. But what respectable man in the City of London would put himself forward to oppose a gentleman against whom personally he had no feeling? Practically the Articles of Association asserted that the shareholders had not one iota of power. The proxies presented for the last meeting at the office of the Company more than 48 hours before the time appointed for the meeting were refused, on the ground that according to the Articles of Association they should have been deposited 48 hours before the day of the meeting. Everyone, however, knew that if proxies were handed in 48 hours before the meeting, that would be sufficient; but in the case of this Company the articles were against it. It was simply "crying over spilt milk" to protest against the articles as they stood — they must be altered. He thought the policy of the committee should be to submit an amendment to the report of the Directors, against the expenditure for proxies and any objectionable paragraph in the report, but the amendment must be so couched as not to enable it to be said by the Chairman that it was "a negative." Some of them might remember that he proposed a resolution at one of the meetings opposing the election of Lord Montagu Hay. For that resolution two hundred hands were held up, while there were only ten against it. Lord Monck, however, on that occasion said he would use the proxies, but the meeting rose with indignation against such an idea. His lordship then asked to be allowed to retire to another room to consult with the Directors, and when they came back they said the proxies would not be used, but the voting would be kept open until five o'clock. He (the speaker) knew as a fact that they then sent a message to members of the Stock Exchange to tell their friends it was necessary to go to the meeting of the Company and vote. They did so, and the resolution he had brought forward was defeated in that way. He thought that the Directors of the Company were excellent business men; but they were vastly over-paid. If they made a calculation of how much the directors of telegraph property had received it was scandalous. [A Voice: "With nothing to do."] There was, no doubt, plenty to do. Was it not, however, a gross injustice that the salaries of the Directors should be so enormous when those of them who were in business must know that their profits from that business had been reduced by 50, 60, 70, or 80 per cent.? Their remuneration as Directors had not been reduced, notwithstanding the fact that those for whom they worked, the shareholders, had suffered considerably in having reduced dividends, there ought to be some connection between the prosperity of the shareholders or their adversity and the prosperity and adversity of Directors. He had himself supported an addition to the fees of the Eastern Company's Directors; but he did not mind paying Directors well when the shareholders were prosperous, though he held that they should suffer when their shareholders suffered.

Mr. DAVISON said that from the remarks of the previous speakers and his own careful observation, he gathered that there were really two questions which demanded the serious consideration of the shareholders—one was the Articles of Association, which were quite inadequate to the requirements of the Company as at present constituted, and the other was the magnitude of the renewal fund. The articles required alteration, and the proper way to accomplish that was to have an extraordinary general meeting of the Company called for that special purpose. From every quarter he heard that an alteration ought to be made; but he had never heard it discussed how it should be accomplished. He thought the power should be delegated to a committee of the shareholders, who would go into the question carefully, and make alterations in accordance with the requirements of the present time. As to the renewal fund, there could not, he maintained, be a shadow of doubt that that sum was really larger than was required. Having had some little experience in these matters, he had long ago arrived at the conclusion that the 10 per cent., or £700,000, would be a very proper provision for the Company to lay aside for such contingencies as such a fund was called upon to meet. Were the fund below that amount he would be one of the strongest advocates to bring it up to that, but it was now over £800,000, and they did not know that it was not intended to go beyond £1,000,000. Measures ought to be taken to prevent it from getting any larger, especially when it was apparent that the great body of shareholders were anxious that that should be done, so that the deferred shareholders might have some little justice meted out to them. As the Directors had shown a disposition at the last few meetings to carry their point against the express wishes of the shareholders he thought it behoved them to form a committee for the purpose of checking the tendency to further increase the renewal fund. He supported the views which had been enunciated by the Chairman and Mr. Jackson.

The CHAIRMAN said he thought Mr. Prust was labouring under a little mistake. Mr. Prust had stated that the fund of £850,000 was now under the protection of the shareholders, and that at his suggestion the Directors had agreed that the fund should not be used without the sanction of a meeting of the shareholders. The Directors took quite a reverse decision.

Mr. PRUST said he thought his motion was agreed to.

Digitized by Google

Mr. JACKSON: Oh, no. If Mr. Prust referred to the report of the meeting he would find that Mr. Chester's resolution—which he believed was Mr. Prust's originally—was out-voted enormously by the proxies.

Mr. NEWTON said that that was so.

The CHAIRMAN added that the Directors went to the poll, but they (the opposing shareholders) did not. Mr. Chester's proposal was, "That no contract for the laying of any new cable be entered into by the Board of Directors without first obtaining the consent of the shareholders in public meeting." That was discussed, and lost in the manner stated.

Mr. DAVISON: It was out-voted?

Mr. JACKSON: Enormously.

Mr. PRUST: Not by the shareholders present, but by the proxies.

The CHAIRMAN: Yes, that is so; but the matter is entirely in the Directors' hands.

Mr. DAVISON said he could not agree that proxies should be abolished. As a rule, the shareholders at a meeting represented one-tenth of the entire number, and he thought it would be rather an error to hold that the other nine-tenths should not record their opinions. He was aware that proxies were improperly used occasionally, and even the resolution just read rather showed that, but he did not think that that fact formed a reason for their condemning proxies altogether.

Mr. GRIFFITH agreed with what had been said, that the shareholders should feel indebted for the labour which had been undertaken by the provisional committee in the interests of the shareholders. When they considered that the cables in existence were more than sufficient to do double the amount of business which they now had to do, the time had come when their large insurance fund need not be increased. An additional argument in favour of that view was that there were other cables besides their own, that they were able to carry the messages, and that even were the Company's cables to break, their earnings would be the same for 12 months. As to the question of proxies, it might not be wise to allow directors to issue proxies, but if they did he thought they should pay for them themselves. Though he would not exclude absent members of the Company from expressing their opinions, he would not allow the Company to be mulcted of a large sum in paying for the dilatory conduct of those who did not come to the meetings. The shareholders were not satisfied with having their funds wasted, their votes ignored, and with being played with time after time by the Directors. It was the shareholders who represented the Company, though it was true that the Directors were the managing partners. The Directors, however, did not represent the views raised at each annual meeting. He, like the other shareholders, had attended these meetings from time to time, and the expressions of opinion uttered had been strongly condemnatory of the Directors; decided views had been expressed that reform was needed, and that the time had come when that reform should be carried out. The statement was quite correct that those reforms could not be carried out without revising the Articles of Association. Those articles had been drawn in a very unfair way, and had given powers to the managing partners which they ought not to possess. The managing partners were thus able to override the interests and wishes of the shareholders at large. That was never the intention of Parliament. He was looking at the articles a short time since, and there was one merit about them as they were originally—namely, that the reserve fund was not to be used simply as an insurance fund, but for the general benefit of the Company, so that dividends might be equalised, and other contingencies provided for occasionally. The Directors, however, saw that that would diminish their power, and a special meeting was called to alter the articles. Alterations were then made, by which this power had been taken away from the shareholders at their general meetings, and confided to the Directors alone. They were therefore not mere socialist reformers. They simply wanted those rights which they formerly possessed, and they would succeed if they only had the courage to go on. Any articles could be altered by two special meetings called in accordance with the Act, and it was therefore a question whether they who held the views expressed at that meeting would see them carried out or not. They knew from the views expressed at the annual meetings that they had the support of the London shareholders and of those who came up from the country to attend the meetings; and he therefore thought they might look forward with some confidence to the time when they would see their views carried into effect.

In reply to a SHAREHOLDER, who said that his dividend had been reduced without competition existing,

Mr. GRIFFITH stated that on one occasion the Directors anticipated competition, and lowered the rate per word long before the competition.

Mr. PRUST: And lost £70,000 by doing so.

Mr. DAVISON stated that he had not been aware of what Mr. Griffith had stated—that the Articles of Association had originally been drawn up in favour of the shareholders, and had been altered.

Mr. STOCKDALE replied that Article 28 had been altered by special resolution of an extraordinary general meeting of the shareholders.

Mr. DAVISON: The very thing we wish now to restore.

Mr. STOCKDALE: Exactly. It was done by the proxies.

The CHAIRMAN stated that the committee had heard the remarks which had been made, and quite agreed with them, but before any further steps could be taken they must appoint a committee. Probably those who had heard the remarks which had been made would then see if they could carry them out.

Mr. PRUST was asked to be a member of the committee, but stated that he was so situated that he could not accept the invitation.

On the motion of Mr. STUBBINGS, seconded by Mr. PRUST, Mr. Davison was elected a member of the committee.

The CHAIRMAN said they wanted a committee of seven.

Mr. PRUST inquired whether Mr. Griffith would give the shareholders his assistance as a member?

Mr. GRIFFITH replied that he would be very glad to do so.

Mr. DAVISON thought that the qualification named of £5,000 might debar some gentlemen from joining the committee. He did not say that on his own behalf, as, unfortunately, he held more than that amount.

Mr. STOCKDALE stated that their object in naming that amount in the first instance was that the committee were a self-elected body, and that unless each member had a considerable holding in the stock of the Company the shareholders might get an impression that they had other motives than the general welfare of the whole body.

Mr. DAVISON: What is the qualification of a Director?

Mr. STOCKDALE: £500.

Mr. DAVISON said he thought that if a shareholder held £3,000 that would be quite sufficient.

Mr. JACKSON replied that probably there would be no objection to a gentleman if he had £3,000. Or the shareholders might say that if the effort now to get seven members was not successful, those who formed the committee should have power to add to their number.

Mr. NEWTON said he thought that if two gentlemen were appointed from the meeting, and there was power given to elect the others, it would be all that was necessary.

Mr. GRIFFITH said he thought that the committee would approach the Directors with quite sufficient weight.

The CHAIRMAN stated that the four members of the provisional committee held among them £80,000.

Messrs. Davison and Griffith were then severally appointed members of the committee.

On the motion of Mr. DAVISON, seconded by Mr. PRUST, the members of the provisional committee were elected members of the committee now appointed.

In reply to the Chairman,

Mr. NEWTON said he would rather not be on the committee, but would gladly give any assistance he could.

A vote of thanks to the Chairman closed the proceedings.

NOTES.

NOTICE OF REPAIR.—The cable between Trinidad and Demerara is repaired.

TOWN LIGHTING.—It is stated from La Creuse, that the town of Bourganeuf (3,700 inhabitants) is about to be lighted by electricity.

H.M.S. "INFLEXIBLE."—This vessel is to be fitted with electric indicators on the plan designed by Lieut. Lloyd, of the "Excellent."

THE PARISIAN OPERA HOUSE.—The installation at the Opera is now complete, and about 1,684 Edison lamps do nightly duty.

AUSTRALIA.—The Government of Western Australia has invited tenders for the construction of about 900 miles of telegraph wire.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 8th inst. amounted to £3,091.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ended 31st December, 1885, were £3,825.

THE TASMANIAN DUPLICATE CABLE.—A telegram from Flinders states that the duplicate cable between Victoria and Tasmania was being laid successfully.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—It is notified that the directors of this company declared, on the 13th inst., a dividend for the past half-year of 3s. per share.

FOR WORKS.—The artillery workshops of Saint Thomas d'Aquin, Paris, are about to be lighted by electricity. Gramme regulators will be used, and incandescent lamps of 12 candle-power.

AN INTERESTING CONFERENCE.—An interesting conference took place a few days ago in the municipal offices of the 4th Arrondissement at Paris upon the electric lighting of the Tour St. Jacques.

LIGHTING OF A TRANSATLANTIC LINER.—The new transatlantic liner, the "Gascoyne," which has just been launched at La Seyne, near Toulon, will be lighted throughout by electricity.

THE TELEPHONE IN ITALY.—The telephone is likely to go ahead in Italy. Special laws are being framed with a view to promote the industry, and concessions for fifteen years are to be given to eligible persons.

THE VAN RYSSELBERGHE SYSTEM IN AMERICA.—By means of the Van Rysselberghe system articulate speech has been successfully transmitted between New York and Chicago, a distance of about 990 miles.

COMMUNICATION BY SUBMARINE CABLES.—Recent issues of our Italian contemporaries *Fanfulla* and *La Tribuna* contain an account of an interesting conference, initiated by Cav. Salvatore Raineri, upon "Telegraphic Communication by Means of Submarine Cables."

THE HAMMOND COMPANY.—Mr. William Theobald, liquidator of the Hammond Electric Light and Power Supply Company, has given notice that he is prepared to pay the debenture holders upon application.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 8th inst. were £2,336, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

THE AURORA BOREALIS.—A magnificent display of Aurora Borealis was witnessed on Saturday evening from places in Forfarshire and Kincardineshire. It is said that during its continuance the electric bells in many railway signalling cabins were rendered useless.

THE TELEPHONE IN AUSTRIA.—The use of the telephone is fast extending in Austria. Communication has just been established between the town of Gleichenberg, one of the principal industrial centres of Bohemia, and Gablonz, another manufacturing town twelve miles distant.

THE INTERNATIONAL ELECTRIC COMPANY.—At a general meeting of this company, held on Wednesday the 13th inst., resolutions for the voluntary winding-up of the company were confirmed, and Mr. Ernest Cooper, of the firm of Cooper Brothers and Co., was appointed liquidator.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The Directors of this Company, in their annual report, state that, after providing for the dividend of 2¾ per cent. already announced, and supplementing the renewal fund by £10,000, the sum of £3,459 will remain to be carried forward.

THE ELECTRIC LIGHT AT WILLIS'S ROOMS.—On the occasion of the exhibition of pictures of the Alpine Club, three of these rooms were lit up by forty 20 candle-power Woodhouse and Rawson incandescent lamps, suspended from the ceiling. The work was done in accordance with the rules of the Phœnix Fire Insurance Office.

GERMAN UNION TELEGRAPH COMPANY.—This company is paying, as from the 8th January, the dividends for the past financial year on the Five-and-a-Half per Cent. Original Preference shares, as also an interim dividend of 4 per cent. upon the dividend due in respect of the Original stock on the 1st of May of this year.

STRUCK BY LIGHTNING.—Two labourers, father and son, named Tench, were killed by lightning on 25th November near Ballarat, in Australia. They were engaged in splitting in the neighbourhood of the Gong Gong Reservoir, and while sheltering themselves under a tree from a thunderstorm they were struck dead by lightning.

HONOURS.—We are glad to learn that M. Gaston Planté has been nominated Officer of the Legion of Honour. The same distinction has also been conferred upon M. Clémandot and M. Jules Duboscq, while M. Ducretet has been named Chevalier of the same order. M. Renard and M. Krebs are nominated Officiers d'Académie.

WINTER THUNDERSTORM.—The destructive hurricane which swept over the midland and western counties on Wednesday morning was attended in the neighbourhood of Aylesbury by a terrific thunderstorm. The roof of a farmhouse at Weedon-hill, near that place, was struck by lightning and greatly damaged, as was an adjoining wall.

THE DIRECT UNITED STATES CABLE COMPANY.—We are informed that the Board of Directors of this company resolved on the 8th inst. upon the payment of an interim dividend of 3s. per share, being at the rate of three per cent. per annum for the quarter ended 31st December, 1885, such dividend to be payable on and after the 23rd inst.

RE-OPENING OF A TELEGRAPH SCHOOL IN BOGOTA.—It has been decided to re-open the Telegraph School in Bogota, U.S. of Colombia, which, owing to the late war, has been closed for over a year, and to add to it a special department

Digitized by Google

for women. The Inspector-General of Telegraphs, Mr. Ernest Danvers, has been appointed the Director-in-Chief.

THE INVENTIONS EXHIBITION.—In explanation of the large difference there will be when the accounts are made up between the profits of last year's Exhibition and those of the "Fisheries," the *Daily Telegraph* states, among other causes, that the electric lighting, which cost the "Inventions" a large sum, was almost entirely a gratuitous outlay by exhibitors in 1883. We altogether doubt this statement.

EARTHQUAKE SHOCKS IN ROUMELIA.—A Reuter's telegram, dated Philippopolis, Jan. 9, states:—"A slight shock of earthquake occurred here at eight o'clock yesterday evening, and was followed at five minutes to four this morning by several shocks of a more violent character, the vibrations lasting nearly five seconds. The movement was in a south south-easterly direction."

THE OXFORD LOCAL BOARD AND UNDERGROUND WIRES.—At the last monthly meeting of this board the recommendation of the General Purposes Committee that application be made to the Postmaster, asking him to remove the nine telegraph poles north of St. Margaret's-road, and to substitute underground wires, was adopted.

CENTRAL STATIONS IN FRANCE.—The central lighting station on the Edison system at St. Etienne is making a great success. More than 2,000 lamps are in operation, and it has already been found necessary to increase the number of dynamos. The station at Dijon is also work ing up to its full capacity. A third circuit has been added, and the number of lamps increased from 375 to 500.

PRIVATE BILLS IN PARLIAMENT.—Saturday was the latest time allowed by the regulations of Parliament for the deposit of petitions alleging non-compliance with the Standing Orders in respect of the first 100 Bills in the general list. The following is among the petitions lodged, with the titles of the Bills in regard to which non-compliance is alleged:—West London Electric Lighting Company.

THE INDIAN TELEGRAPHS.—The largest contract for iron-work in connection with telegraph work in Staffordshire has just been placed by the Indian Telegraph Department with Messrs. Bayliss, Jones, and Bayliss, for telegraph poles and accessories. The aggregate value is about £50,000, and to execute the contract in six months special plant is being laid down, and extra hands are being taken on.

THE BAUDOT TELEGRAPH SYSTEM.—The rotatory speed of the Baudot distributors varies between 155 and 180 revolutions per minute. On certain lines a speed of 210 revolutions is obtained. Taking 165 as a mean, the single instrument can transmit 165 letters, or 25 words, per minute, or 1,500 words per hour. The sextuple instrument transmits 900, or a total of 400 to 450 messages of 20 words per hour.

BOOKS RECEIVED.—"Magnetism and Electricity for the Use of Students in Schools and Science Classes," by H. C. Tarn, M.C.P., F.S.Sc. (London and Edinburgh: W. and R. Chambers). This is a little work in which an earnest attempt has been made to provide the student with all the knowledge necessary to enable him to make sure of a first class in the elementary examination of the Science and Art Department.

BURMAH.—The following telegram has been received at the War Office from General Prendergast, dated Bhamo, Dec. 29, 1885:—"The water is so shallow that steamers cannot approach nearer than two miles from Bhamo. Telegraph line in disrepair all the way up. Have arranged for its re-establishment from Mandalay to Tsengoo, and will continue the line to Bhamo when operators and instruments have been received."

THE BURTON TOWN COUNCIL AND THE TELEPHONE.—At the last monthly meeting of this Council it was suggested that the utility of the suburban fire stations should be increased by telephonic communication between them and the borough brigade station. The Fire Brigade Committee, at all events, might consider whether the advantage would justify the cost which would be incurred. It was promised that the suggestion should be considered.

THE MANCHESTER ART GALLERY.—At the last monthly meeting of the Manchester City Council, Mr. Alderman Hopkinson, in moving the adoption of the proceedings of the Art Gallery Committee, said the autumn exhibition was now closed. The exhibition had been more successful than any that had preceded it in all respects. The electric light had been an immense comfort and advantage, although it was not altogether perfect yet.

TOYNBEE HALL.—We have received the syllabus for the ensuing term, relating to the Whitechapel Centre of the London Society for the Extension of University Teaching, at Toynbee Hall, 28, Commercial street. The list of lectures includes a course of ten by Dr. J. W. Waghorn on "Voltaic Electricity," with experiments, which commenced on the 12th inst., and will be continued every following Tuesday during the term, at 8 p.m. The charge for each course of lectures at this Institute is only one shilling.

JAPAN.—S. Tegima, Minister of Education, Tokio, Japan, has obtained leave to have translated into Japanese Prof. Guthrie's syllabus of instruction in elementary practical physics as pursued at the Physical Laboratory of the Normal School of Science and Royal School of Mines, South Kensington. The Japanese Government propose to introduce this system of practical instruction into the elementary schools as well as into the normal schools of Japan. Prof. Guthrie has promised to write a preface to the translation.

THE PATENT LAWS.—A preliminary meeting of the Committee appointed to inquire into the administration of the Patent Laws was held on Wednesday. There were present Baron Henry de Worms, M.P. (who was appointed chairman), the Earl of Crawford and Balcarres, and Sir Farrer Herschell. Arrangements were made relative to the subsequent sittings of the committee, by whom a thorough investigation is to be made not only into the application of the laws bearing on patents, but into the organisation of the Patent Office.

SAD DEATH OF A TELEGRAPHIST.—On Saturday afternoon a youth named Frank Helliwell, junior clerk in the telegraph department of the Sheffield Post Office, lost his life while skating on Low Forge Dam, Wadsley Bridge, near Sheffield. About fifty persons were skating there, when the ice gave way beneath two men named Arthur Roberts and Richard Atkinson, and deceased, who was close behind them, followed them into the water. Roberts, who could swim, managed, with the assistance of the spectators, to save himself and Atkinson, but Helliwell was drowned. His mother, a widow, is postmistress at Hellsborough, a Sheffield suburb.

THE VIOLENT STORM IN THE MIDLANDS.—During the violent storm which swept over the Midlands on Wednesday last, a terrific gust of wind carried away the roof of the Great Western Railway Station at Stratford-on-Avon, a large structure 150ft. in length. Fortunately, at the time of the occurence, no train was in the station, nor was one expected, so that the platforms were deserted by passengers, otherwise a terrible calamity must have been the result. The telegraph

Digitized by Google

posts were blown down or broken by the falling *débris*, and the wires lay upon the ground. This completely cut off all telegraphic communication with the town, and totally disorganised the work of the post office.

KING'S COLLEGE OLD STUDENTS' DINNER.—The annual dinner of the old students of King's College was held in the great hall of the college on Tuesday evening. The Rev. Canon Ince, D.D., Regius Professor of Divinity, Oxford, presided, and among those present were the Rev. Prebendary Wace (principal of the college), General Sir Richard Wilbraham, K.C.B.; Mr. J. Shires Will, Q.C., M.P.; Mr. T. Eccleston Gibb, M.P.; Dr. Hopkinson, F.R.S.; Mr. W. H. Preece, F.R.S.; Prof. Stanley Leathes, Prof. Robinson, Prof. Seeley, Prof. Adams, Prof. Shelley, Prof. Warr, Prof. Douglas, Prof. Curnow, Prof. Cutter, the Rev. Henry White, Mr. John Hernaman, Mr. A. H. Crockford, and Mr. W. E. Limes.

EARTH CURRENTS.—A very interesting letter has reached us relative to the occurrence of exceptionally strong earth currents on the cables of the Eastern Telegraph Company on Saturday, the 9th inst. From Singapore very strong currents are reported on the China coast, Philippines, and Cochin China cables from about 3 to 5 p.m., and on the Java and Australia cables from 4 p.m. until late in the night, Singapore time. At Corfu the earth currents were noticeable all day on the Trieste cable, but were most powerful between 7 and 11 p.m., and at Gibraltar very strong currents were observed on the Malta, Lisbon, and Villa Reale cable. On the following day the phenomenon was also apparent, but was not so marked as on Saturday.

THE ELECTRIC LIGHT IN BRUSSELS.—The *Chronique des Travaux Publics* announces that it is proposed to electrically light the district of Brussels comprised between the Rues de l'Ecuyer, d'Arenberg, from La Montagne and the Marché-Aux-Herbes on one side, and the Rues des Bouchers and des Dominicians on the other side. This proposal is received with considerable interest, in that the quarter mentioned contains the galleries Saint-Hubert, with the two theatres, l'Alcazar, and a number of large cafés and public buildings, in which the electric light might advantageously be employed. The new theatre of the Bourse, which was opened on the 30th of last month, has only received a small installation, consisting of six lamps, supplied by 360 Bunsen batteries of 60 cells.

THE BELL TELEPHONE CASE.—Associated Press reports in America state that the Interior Department has decided to recommend that the Attorney-General authorise suit to be brought in the name of the United States to test the validity of Bell's original patent. Although the full text of the decision will not appear for some days, it is said that it will set forth, among other things, that "the specification of Bell's patent contains nothing about the capability of Bell's instrument to transmit articulate speech, but only claims for it the power to transmit 'vocal sounds;' that an instrument may transmit 'vocal sounds' without being a speaking telephone; and that, in point of fact, Bell did not invent a speaking telephone until after the issue of his patent, as appears from the record."

THE TELEPHONE LINES AND THE LATE SNOW STORM.—The National Telephone Company writes to inform us that during the late snow storms, although they have different gauges of wire, such as iron, copper, and bronze, on the same poles, there was not a single break-down recorded, although one of the junction poles, 105ft. high, carries 190 wires, consisting of No. 17 copper, No. 11 covered iron, and 18 G bronze. The trunk lines to Loughborough, Long Eaton, and Ilkeston, and three suburban junction lines also escaped interruption. The first-named trunk loop exceeds 40 miles in length, being connected on the metallic system, and passing through a very wooded district. The following fires were signalled within the borough of Nottingham during the month of December, 1885, viz.:—Two by telephone, and 12 by street fire alarms.

THE GERMAN TELEGRAPHS.—Herr Stephan, the Minister of Posts and Telegraphs for the German Empire, in a report just presented to the Emperor, gives some account of the progress that has been made in internal communications throughout Germany during the last four years. Telegraph stations have in that period been increased by 1,639. They now number 7,535, or one office to every 5,000 inhabitants. No statement of revenue and expenditure is given in this report, consequently we can form no opinion as to the financial results of Herr Stephen's administration; but it is said that the German telegraph system is "not conducted on commercial principles," which we can quite believe seeing that this energetic minister has done his best to compel English cable companies to carry on their business for the benefit of the world at large, and at a loss to themselves.

LIGHTHOUSE ILLUMINANTS.—In a paper recently read before the Edinburgh Royal Society by Mr. J. Stevenson, M.I.C.E., on lighthouse experiments, it was stated that the electric machine proposed to be employed at the Isle of May was a Brush machine, in which the current was continuous. An altogether unlooked for difficulty had been experienced, however, by the agents for this mode of lighting, in constructing a satisfactory lamp; and this difficulty had not yet been wholly overcome. But the light from the alternating current machines of De Méritens had been dipped satisfactorily at the South Foreland, not only by the arrangement which he (the author) suggested, but also by another mode subsequently suggested by his late pupil, Mr. Brebner, jun., so that, by either of these methods, there could be no doubt a light from the electric lamp could be dipped to suit any required conditions.

THE DISTURBANCES IN KHORASSAN.—A telegram dated Teheran, Sunday, says: "News received since yesterday from Meshed shows that telegraphic communication has again been established between that place and Teheran. It is found that the office at Meshed had been seriously damaged and the wire destroyed in three places. Further advices through Reuter's agency and dated Teheran, 10th inst., report that disturbances have broken out at Meshed, in consequence of the Governor of Khorassan again attempting to increase the taxation. Telegraphic communication was unfortunately interrupted in consequence of a heavy fall of snow, and great apprehension was felt here, owing to a rumour that the Governor had been murdered. Telegraphic communication was restored last night, and the central Government immediately telegraphed in reply to the priesthood that the inviolability of the Shrine would be respected."

ELECTRIC LIGHTING CONTRACT.—From the *Contract Journal* we notice that the following tenders have been received at Egremont, Cheshire, for fitting up the electric light on six passenger steamers, for the Wallasey Local Board:—J. J. Marr and Co., 31, Moorfields, Liverpool (accepted); J. D. F. Andrews and Co., Woodside Electric Works, Glasgow; Siemens Brothers and Co., 12, Queen Anne's-gate, Westminster, London; G. Durham, 62, Shaw-heath, Stockport; H. Bury, 27, Arcade-chambers, St. Mary's Gate, Manchester; W. L. Fleming, 15, Stanley-street, Liverpool; the Simplex Electric Light and Plant Company, Valley Mills, Eccles, near Manchester; Laing, Wharton, and Down, 8 and 9, Holborn-viaduct, London, E.C.; Gardners (J. and C.

Digitized by Google

Christie), 453 and 454, Strand, London, W.; Bailey and Grundy, Amberley-road, Paddington, London: the Manchester and District Edison Electric Light Company, 19, Victoria-buildings, Manchester.

PERSONAL.—The appointment of Señor Saturnino Islas, of the City of Mexico, to the position of Director-General of all the Government telegraph and telephone lines in the Republic of Mexico appears to have given satisfaction. Señor Islas is well fitted for the high position conferred upon him, having had many years' experience as superintendent of telegraphs for the Mexican Railroad, besides having been prominently identified with the telephone and electric light in the Mexican Republic. The work of reform inaugurated is already spoken of in high terms, and a bright future is apparently before him. He is said to be possessed of great executive ability, and his integrity is known to be irreproachable. It is interesting to know that Señor Islas was trained in the English Railway Company, whose lines connect Vera Cruz with the City of Mexico. He was afterwards telegraph superintendent of that company. He was before that an officer in the Mexican Army (during the French invasion), and distinguished himself.

THE TELEGRAPH SYSTEM IN VICTORIA.—The statistical return of the telegraph system for eleven years ended 1884 shows the following relations:—The number of stations opened in 1874 was 148, and the lines carried 4,293 miles of wire. The number of telegrams sent was 705,108, of which 121,285 were free, the amount received for the messages being £42,825. In 1884 the stations had increased to 404, the miles of wire to 8,055, the number of telegrams to 1,594,296, of which 473,670 were free, and the revenue of £89,077. The greater portion of the materials required for this telegraphic extension were imported from the United Kingdom; for example, the value of the materials exported from the United Kingdom in 1884 was £12,020 out of £15,304, the value of the materials received by Victoria from all quarters. Further, in all probability £245 of this value must also be put to England's account, the materials going through New South Wales instead of direct. Of the rest Antwerp contributed £540, Hamburg £1,037, Marseilles £341, and New York £121.

ELECTRIC LIGHTING OF A CHURCH.—The church of St. George's, Hanover-square, was lighted on the 10th inst. at the afternoon and evening services by the Swan incandescent electric light. Three large electroliers, with some thirty lamps apiece, besides a large number of smaller branches, gave a light which for brilliancy proved far superior even to the broad daylight of this misty mid-winter season. The little lamps glowed throughout the day, and set off the fine interior of the famous church with matchless effect. The experiment is part of a large scheme of domestic lighting originating with Sir Coutts Lindsay's company at the Grosvenor Gallery. At the back of the gallery library a large installation has been started, with machinery of 600 horse-power and two powerful batteries. From this centre wires radiate in various directions, and the electric current is supplied in buildings just like water or coal gas. Already a number of tradesmen avail themselves of the opportunity of using the electric light at their establishments without having the trouble and expense of a separate installation of machinery. The farthest point from New Bond-street at present reached is the Café Royal, near the bottom of Regent-street.

THE COLCHESTER INSTALLATION.—At a recent meeting of consumers of electric light at Colchester, the following resolution was agreed to:—"That in the event of the Electric Light Company being willing to refund 75 per cent. of the amount paid for the installation of the light on their premises, the consumers will offer no opposition to the light being discontinued." The Chairman, in the course of the proceedings, stated that the Company were in treaty for the sale of their plant and works as they stood. A consumer remarked that the Company had promised to give them 20 candle-power; but they had distinctly failed to do so. He was willing to pay for the light they had actually had, but not for the light they ought to have had. It was decided that the liquidator (Mr. Pannell) be requested to make some reduction, in consideration of deficient light, upon all unpaid accounts; taking into consideration that some of the consumers had already received reductions. The resolution was carried. It was understood that the meeting agreed not to offer any opposition to the discontinuance of the electric light; but only on condition that the proposals embodied in both the resolutions were accepted by the company.

ELECTRIC LIGHTING AT LEEDS.—The arrangements for illuminating the Leeds Victoria Hall by electricity are so near completion that two of the arc lamps will be placed in position within a few days, and an experiment will be made in the presence of a number of members of the council. The eight arc lamps ordered have been received, but owing to the fact that the incandescent lamps of Messrs. Crompton remain in the position they were placed in for the last musical festival, the new lamps cannot all be put up yet. The arc lamps now to be introduced are on the Brockie-Pell focussing principle, and will each give a light of 2,000 candle-power. The light will be enclosed in large opal globes, 22in. in diameter, surmounted by an ornamented brass corona, above which is an enclosed cylindrical case about 18in. long, containing the automatic machinery by which the light is regulated. The carbons, which are about 2ft. in length, will burn for 18 hours. The lamps, when fitted, will be worked by 45 batteries, stored in the crypt, and charged as required by the dynamos already existing in the basement of the Municipal Buildings, whence the current will be carried by a subway into the Town Hall, and thence through the false roof into the wires which form part of the ornamental pendants by which the lamps will be suspended from the ceiling of the Victoria Hall.

THE ELECTRIC LIGHT IN HULL.—A very successful installation of the electric light has been put down at the establishment of Messrs. Barnett and Scott, manufacturing art jewellers of Whitefriargate, Hull. The plant is most complete and extensive, and consists of a six horse-power Otto gas engine, which has been laid down by Messrs. Crossley Bros., under the superintendence of Mr. Crabtree, their agent; a Ferranti dynamo and Siemens exciter, the countershafting and pulleys being supplied and fixed by Messrs. Amos and Smith, Hull. The lamps are the Messrs. Woodhouse and Rawson's incandescent of 20 candle-power each, and they are arranged suspended from chandeliers on either side of the extensive shops, six lamps forming a cluster. A sun light of lamps is fixed in the centre of the ceiling, and eight lamps in each compartment of the window. The whole of the lamps in the shop give an illumination equal to 2,000 candle-power, giving a most brilliant effect. The offices and workshop will also be fitted with the same light. A belting fixed to the countershaft of the engine and connecting the lathes and batteries in the manufacturing department will be very beneficial, by giving a speed which cannot be attained by manual labour. The installation has been put down by Mr. Thomas Muse, electrician, Hull.

LIGHTING AT GLASGOW.—The experimental lighting by electricity of the Central Station in Gordon-street, Glasgow,

Digitized by Google

has proved so successful that the system is about to receive important additions. The electricity is generated in a large engine room under the station by two Brush machines, each of 25,000 candle-power, while two Gramme machines, each of 4,000 candle-power, are available when required. The Brush machines are, however, sufficient for present purposes at the station, where 48 arc lights are nightly in use, and have never once failed in giving out a brilliant and perfectly steady radiance. Within a few days five or six lights will be added to the existing number. Of these one will be placed outside the covered way at the Gordon-street entrance, showing as far as Buchanan-street and Hope-street, another at the exit in the latter street, and a third will be erected on the parapet of the Argyll-street Bridge. The engines fitted up are powerful enough to supply electricity to the Bridge-street and Eglinton-street stations, to which it will doubtless be applied within a short time. In the Central Station Hotel, it may be added, nearly 200 incandescent lights are in use, supplied by an Edison-Hopkinson dynamo machine. The whole arrangements have been carried out under the superintendence of Mr. A. S. Dunn, the telegraph superintendent for the Caledonian Railway Company.

Electric Lighting at Hatfield House.—On the occasion of the county ball, given by the Marchioness of Salisbury, at Hatfield House, on the 6th inst., the following arrangements were made for the lighting by electricity of the house and grounds :—The principal rooms, galleries, and grand staircase were illuminated by upwards of 900 Swan 20 candle-power lamps, the principal power for these lamps being derived from two waterwheels on the River Lea, which is a mile and a quarter distant from the house. The machinery used for generating the current consisted of two Siemens alternating machines, one 16-light Brush, and one Siemens direct-current machine, the latter being driven by a 16 horse-power Otto gas engine. The terraces and approaches to the house were lighted by six Clark-Bowman arc lamps, the current for these being supplied by an H Gramme machine, driven by a traction engine near the house. The lighting was in every respect a thorough success, and gave great satisfaction, there being not the slightest interruption to the working during a period of sixteen hours. The whole installation was carried out by Mr. Shillito. It may be remembered by our readers that the Marquis of Salisbury has been a pioneer in the matter of electric lighting and the use of electricity, and that his lordship has utilised this agent in a variety of novel ways by the transmission of electrical power, such as for grinding corn at farms situated at some distance from the water-power, pumping water, and driving the ventilating apparatus at the house, driving the lathes and saws in the workshops, pile driving, dredging, and cutting weeds in the river, &c.

The Electric Light at Edinburgh.—The North British Railway Company have just extended the electric light into the booking hall and refreshment and waiting rooms of the Waverley Station, Edinburgh, as well as the entrances, platform, and rooms of the Suburban Railway there. As is well known, the Waverley Station has been illuminated by electric light for some years, and its suitability and cheapness during that time has, it is understood, led to the extension referred to. While the lighting up to the present time has been on the arc system, the new light is on the incandescent principle, and the lamps used in the refreshment rooms are enclosed in dioptric and opaque globes, rather a pleasant effect being produced by the suspension from the ceiling of ornamental lamps by an almost invisible wire. The others are bulb-shaped, about 4in. long, and from 2in. to 1in. diameter, made of clear glass. In the rooms the new light is much superior to gas, but on the Suburban platform, probably owing to the number of lamps being too few, the light cannot be said to be any greater improvement. Altogether about 135 Brush-Victoria lamps have been introduced, each of which is of 20 to 30 candle-power. These are arranged in groups, so that, for instance, one room or entrance may be lighted, while another is not. The present engine will suffice for the additional driving power wanted, though a new Brush-Victoria dynamo, similar to that to be supplied to the Isle of May lighthouse, has been provided. Besides economy in production, it is believed that the electric light will save a repetition of damage to the ornamental ceilings of the refreshment rooms which has been caused by gas during the last few years. The Anglo-American Brush Electric Light Corporation executed the work, under the supervision of Mr. Giepel, their superintendent for Edinburgh, and Mr. Thomas Carsewell, of the engineering department of the North British Railway. The railway company, it is understood, estimate that the lighting of the station will be effected at a cost of about something like half the price of gas.

Electric Tramcars in Berlin.—We have received a further batch of letters and newspapers from our correspondent in Berlin, giving us full accounts of the trials and progress of Reckenzaun's electrically propelled tramcar. From these accounts we learn that its success is quite assured. We are glad of this, but must confess that we regret that an English invention has had to be exported to Berlin in order to find practical development, and we can see in this incident only another sign of the abnormal position into which electrical matters in general have drifted in this country, through causes which have unfortunately not yet disappeared. Mr. Reckenzaun's tramcar—with the principles and construction of which our readers are well acquainted—has now been running daily in Berlin full of passengers, and last week a number of directors of different tramway companies from all parts of Germany inspected the invention. The following is a translation of an article relating to it from the *National Zeitung* of 10th inst. :—"Mr. G. A. Plewe, who represents the invention of the engineer, Mr. Reckenzaun, of London, invited the directors of a number of tramcar companies to the trial, among whom we saw represented the different Berlin companies and those of Spandau, Potsdam, Stettin, Magdeburg, &c., and which constituted a jury of competent and influential men. The car ran from the Exhibition through a number of streets to the Brandenburg Gate, near which place an explanation of the experiment was to be given ; but there was no need to wait for that, because the experience was simply this, that the car ran over one of the worst curved lines of Berlin at the rate of an ordinary tramcar without shaking and without shocks or accidents. It was also evident at once that the car could be stopped in a moment by switching off the current, and that the risk of accident to the car itself or to foot passengers is thus greatly reduced. The electrical details of the system are too well known to need description here. Suffice it to say that passengers were able to see that the boxes containing the accumulated electricity were pushed into the car, that they were placed out of sight underneath the seats, and that the taking out and replacing of the boxes occupied no more time than the changing of horses. The accumulators also supply four 20 candle-power Brush lamps. From the outside the car looks like an ordinary one, only that instead of the driver of horses one can see the engineer attending to the switch, and that instead of running on four wheels the electrical car runs on eight small ones. This last novelty very likely accounts for the ease with which the car turns the curves."

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 148.)

The Mechanical Forces and Stresses. Preliminary. The simple Maxwellian stress.

As this is not a treatise upon the theory of Elasticity, it will be only necessary to say so much on the subject of stresses in general as will serve to introduce us to the principal formulæ connecting stresses with the corresponding mechanical forces, which we may find useful hereafter. This can be done very briefly.

A simple stress is either a tension or a pressure acting in a certain line. It implies the existence of mutual force between contiguous parts of the substance in which it resides, and of a corresponding state of strain, with storage of energy in the potential form, *i.e.*, depending upon configuration, though perhaps ultimately resolvable into kinetic energy. Thus if we fasten a cord to a beam, and hang a weight to its free end, the cord is slightly stretched, the work done by gravity during the stretching is somehow stored in the altered configuration, and the cord is put into a state of tension. At its lower end the tension in the cord is equal to the weight attached, at its upper end to the same plus the weight of the cord. The state of strain of course extends to the beam, and to the beam's attachments, and so round to the earth, to which we ascribe the gravitational force, which is somehow stressed across the air to the weight, and from the weight to the earth.

If the stretched cord be in motion in its own line, as when a horse tugs a barge along a canal, there is, besides the transfer of energy through space by the onward motion of the horse, rope, barge and dragged water, carrying their kinetic energy with them, a transfer of energy through the rope from the horse to the barge, and through the strained barge to the water, where it is wasted in friction. The rate of transfer per second equals the product of the tension of the rope into its speed, and the direction of transfer is against the direction of motion.

If motion be transmitted from one machine to another by means of a horizontal endless band, the transfer of energy is through the stretched half of the band, and is again proportional to its speed (and against its motion), and to the difference of tensions of the two sections; a uniform tension meaning continuously stored potential energy.

A pressure is a negative tension. If the tension or pressure in a cord or rod be not uniform in amount across every section, we see at once that any small piece of the cord is pulled in opposite directions by forces of different amounts. Their difference is the mechanical force on the small piece considered, and measures its rate of acceleration of momentum. Thus, if P be the tension across a section at distance x from one end, dP/dx is the mechanical force at that place, per unit length of cord, acting in the direction of x positive. Unless otherwise balanced, it increases the momentum of the cord. Thus $-dP/dx$ is the force that must be applied to keep the differential stress from working. Examples: (1) A vertically hanging cord; unequal tension; applied force gravity. (2) In the endless horizontal band moving with uniform speed, there is no force resulting from its tension except where it changes in intensity, for example where it passes over pulleys. At a pulley where the band gives out energy, the force and velocity product is positive, and where it receives energy, negative. These forces of the stress variation are the negatives of the forces the pulleys exert on the band.

The most general stress considered in the common theory of elasticity consists of three simple stresses (pressures or tensions) acting in three lines at right angles to one another in a substance. Let them be P_1, P_2, P_3 per unit area, parallel to the axes of x, y, z respectively. These are the stress intensities, the former tension or pressure being their surface integrals. By the preceding, the mechanical force due to the stress is equivalent to dP_1/dx in the x-direction, dP_2/dy in the y-direction, and dP_3/dz in the z-direction. The resultant of these three components is the mechanical force per unit volume, and its negative is the applied force needed to preserve equilibrium, or prevent change of motion.

When, as is necessary in general, the axes of reference are not the lines of action of the mutually perpendicular simple stresses, the following notation is the most convenient. Although a tension or a pressure is not a vector in the usual sense, since it, although acting in a certain line, acts both ways, yet we may consider only one side of a stress at a time, and so represent the stress on any plane by a vector. On this understanding, let P_1, P_2, P_3, be the vector stresses per unit area on planes whose normals are x, y, z respectively. These are the forces exerted by the matter on the positive side on that on the negative side of the three planes, and being forces, are vectors. Let the scalar components of P_1 be P_{11}, P_{12}, P_{13}, &c.; and i, j, k, be unit vectors parallel to x, y, and z. Then

$$\left.\begin{aligned} P_1 &= iP_{11} + jP_{12} + kP_{13}, \\ P_2 &= iP_{21} + jP_{22} + kP_{23}, \\ P_3 &= iP_{31} + jP_{32} + kP_{33}. \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (1a)$$

(The first of a double suffix fixes the plane, and the second the direction of the force.) Here there are nine components in a general stress. But examination of the force on a unit cube arising from this stress shows at once that the transverse stresses must be equal in pairs, $P_{12} = P_{21}$, &c., if the force is to be purely translatory, thus reducing the number to six. Then, the translatory force due to the stress is

$$i.\text{div}.P_1 + j.\text{div}.P_2 + k.\text{div}.P_3\,; \quad . \quad . \quad . \quad (2a)$$

i.e., the x-component is $\text{div}.P_1$; &c.

Should, however, we admit the possibility of nine coefficients (as we may do, at least on paper, in some kinds of magnetic and electric stresses), the x-component of the translatory force is not the divergence of P_1, but of its conjugate; thus

$$x\text{-component is not} = dP_{11}/dx + dP_{12}/dy + dP_{13}/dz,$$
$$\text{but is} = dP_{11}/dx + dP_{21}/dy + dP_{31}/dz; \quad (3a)$$

a distinction which disappears when $P_{12} = P_{21}$, &c. Besides this, there is rotatory force arising from the stress, whose vector moment per unit volume is

$$i(P_{23} - P_{32}) + j(P_{31} - P_{13}) + k(P_{12} - P_{21}), \quad . \quad . \quad (4a)$$

which also vanishes when $P_{21} = P_{12}$, &c. Should this be the case, the negative of (2a) is the applied force required for equilibrium. If not, then the negative of (3a) is required to balance the translatory and the negative of (4a) to balance the rotatory force.

There are three applications of this theory of stress. The first is in the dynamical theory of elastic bodies; the second is, after Faraday and Maxwell, in the explanation of forces of unknown origin by means of stress in a medium; and the third application consists in the use of the stresses, not for explanation, but for purposes of investigation.

Thus, as from a given state of stress we derive the corresponding mechanical forces by differentiations, so we may obtain a state of stress that will produce a given distribution of force of any origin by integrations. The former is an exact process; the latter is to a certain extent indefinite; for we may clearly add to the state of stress that gives rise to certain forces any state of stress that gives rise to no forces. We should naturally choose the simplest forms that present themselves, unless there should be reasons against this. We have a choice of formulæ for yet another reason, viz., when it is not the exact distribution of force that is known, but only its resultant effect on a solid body, of which examples will occur later. We need not bind ourselves to the hypothesis that a certain state of stress really exists in a certain case, but merely use the stress vectors as auxiliary functions to assist the reasoning, if the investigations should be assisted thereby.

The gravitational application made by Maxwell requires a pressure along a line of gravitational force combined with an equal tension in all directions perpendicular to it. But the intensity of the stress is something stupendous, being at the earth's surface

$$= \frac{1}{8\pi}\left(\frac{614 \times 10^{25}}{3928.(637 \times 10^{6})^2}\right)^2 = 59 \times 10^{10} \text{ dynes per sq.cm.}$$

or 3770 tons per square inch. [Maxwell made it ten times as

much, so I give the above figures, in which I do not see any error; the unit mass is that of 3928 grams, 614×10^{25} that of the earth, and 637×10^{6}cm. its radius.] In the earth, on the supposition of uniform density, it would be proportional to the square of the distance from the centre. But a very severe mental tension is caused by an endeavour to imagine this stress to really exist. Yet the action of gravitation must be transmitted somehow.

First electromagnetic application. No objection on the score of enormously great stresses being required applies when the electric and magnetic mechanical forces are in question. In fact the method seems peculiarly fitted for their explanation. The cause of this would seem to be twofold. Gravitational matter is all attractive, and is collected in great lumps. The electric and magnetic "matters," on the other hand, are comparatively superficial affairs, and are always in equal amounts of opposite kinds. If, as some suppose, the earth is full of electricity, it might as well not be there, for all the good it does.

As a first simple application, let us confine ourselves to a portion of space in which there are no impressed electric or magnetic forces, and the dielectric capacity, the conductivity and the magnetic permeability are all constants, *i.e.*, a homogeneous isotropic medium. There are three mechanical forces to be accounted for by a state of stress.

[1.] The mechanical force on electrification. This is, per unit volume,

$$E\rho = E.\text{div}.D = pE.\text{div}.E, \quad . \quad . \quad . \quad . \quad (5a)$$

if E and D are the electric force and displacement, and $p = c/4\pi$ the condenser capacity per unit volume. It acts parallel to E, which is the force per unit density.

[2.] The mechanical force called by Maxwell the Electromagnetic force. This is,

$$V\Gamma B = V(kE + p\dot{E})\mu H, \quad . \quad . \quad . \quad . \quad (6a)$$

k being the conductivity, μ the permeability, H and B the magnetic force and induction, and Γ the true current, the sum of the conduction current and that of elastic displacement. It i perpendicular to both the current and the induction, and is in strength equal to the product of their tensors into the sine of the angle between their directions. Its existence in a dielectric is speculative, but it is difficult to do without it.

[3.] A mechanical force that we may call the Magnetoelectric Force. It is

$$4\pi VDG = VD\dot{B} = p\mu VE\dot{H}, \quad . \quad . \quad . \quad (7a)$$

where G is the magnetic current, the time variation of the magnetic induction $\div 4\pi$. Its existence anywhere is speculative, but it is absolutely needed as a companion to the last. It is perpendicular to the electric displacement and to the magnetic current. If v be the velocity, the activity of this force is

$$4\pi vVDG = 4\pi GVvD\,; \quad . \quad . \quad . \quad . \quad (8a)$$

hence $4\pi VvD$ is the magnetic force "of induction," due to the motion, the second form of ($8a$) expressing *its* activity. The existence of this magnetic force due to motion in an electric field was concluded before by general reasoning.

The magnetoelectric force can only exist in transient states. The electromagnetic force exists in steady states as well, but then there must be dissipation of energy going on. The force on electrification is independent of whether the state is steady or transient.

The forces [1] and [3] are explained by a simple Maxwellian stress, electric; whilst [2] is explained by a similar magnetic stress. A simple Maxwellian stress consists of a tension along a certain line combined with an equal lateral pressure. Let U_1 and T_1 be the electric and magnetic energies per unit volume, or $\frac{1}{2}pE^2$ and $\frac{1}{2}\mu H^2/4\pi$. Then U_1 is the intensity of the electric stress, and T_1 that of the magnetic stress. The tension is parallel to the electric force in the one case, and to the magnetic force in the other, the pressures being perpendicular to their directions.

The electric stress on any plane, defined by its unit vector normal N, is

$$(EN)D - U_1.N \quad . \quad . \quad . \quad . \quad (9a)$$

that is, a force parallel to D of intensity EN × tensor of D, combined with a normal pressure of intensity U_1. Similarly, the magnetic stress on the plane is

$$(HN)B/4\pi - T_1.N \quad . \quad . \quad . \quad . \quad (10a)$$

i.e., a force parallel to B of intensity HN × tensor of $B/4\pi$, combined with a normal pressure of intensity T_1. By taking $N = i, j, k$, in succession, we may obtain the corresponding three stress vectors on their planes. But the simple Maxwellian stress is fully defined by the single expression ($9a$) or ($10a$), according as it is electric or magnetic, N being in any direction we please.

To prove that these stresses give the required forces, it is sufficient to differentiate them. The divergence of the N-plane stress vector is the N component of the mechanical force due to the stress. Thus, the divergence of ($9a$) gives the N component of the forces [1] and [3], whilst that of ($10a$) gives the force [2]. As the transformations will occur later in a more general manner, space will not be occupied by them here. Whether these stresses be realities or not (physically), there can be no doubt as to their appropriateness.

The medium is in equilibrium in all places where there is no electrification, or electric or magnetic current. Thus in the region outside a wire supporting a steady conduction current, the stress vectors have no divergence, and there is no mechanical force arising from the stresses. On the plane containing both the electric and magnetic forces, the stress is a normal pressure, of intensity $U_1 + T_1$, acting in the line of transfer of energy. If further the electric and magnetic forces are perpendicular, as when the circuit lies in one plane, we have a tension $U_1 - T_1$ in the line of the electric, and a tension $T_1 - U_1$ in the line of the magnetic force. Lastly, if also U_1 and T_1 are equal, we have left only the previously mentioned simple pressure.

Generally, let the normal N to any plane make an angle θ with E and ϕ with H; then the force on the N plane is compounded of a normal tenison

$$U_1\cos 2\theta + T_1\cos 2\phi$$

and two tangential forces

$$U_1\sin 2\theta, \quad \text{and} \quad T_1\sin 2\phi,$$

the first being in the plane of E and N, the second in that of H and N.

There is another important case (not a steady state) in which the stress reduces to a pressure in one line, viz., in the propagation of a plane wave through a homogenous isotropic nonconducting medium. Let z be distance measured in the direction of propagation, x and y at right angles to z; then if E is parallel to x, H is parallel to y. If we look along z in the + direction, and E be + upward, H will be + to the right. They keep time together in all their variations of intensity at any place, and are of such relative magnitude that U_1 and T_1 are equal. Thus,

$$E = \mu vVHN, \qquad H = cvVNE, \qquad v^2 = (\mu c)^{-1}. \quad . \quad (11a)$$

if v be the speed of the wave and N a unit vector parallel to z. Or if E_0 and H_0 are the tensors (magnitudes, apart from direction) of E and H,

$$E_0 = \mu vH_0, \qquad H_0 = cvE_0.$$

Here, E and H being perpendicular and such that $U_1 = T_1$, the stress is a simple pressure $P = 2U_1 = 2T_1$ in the line of z. The only mechanical force arising therefrom is one parallel to z, due to the variation of P along z. This force is the sum of the electromagnetic and magnetoelectric forces, which are equal, and parallel to z, each represented by $-\frac{1}{2}dP/dz$, per unit volume.

Since the medium is not in equilibrium under the stress P, there is translatory motion in the line of z. This requires the medium to be compressible. Thus a wave of compression travels with the electromagnetic wave. The compression is, however, only an effect of, not the electromagnetic disturbance itself. Thus, in the case of a simple harmonic wave, there is a translatory to and fro motion of the parts of the medium in the line of propagation, accompanying the wave; having double ts frequency, as there are two maxima of pressure in a wave

Digitized by Google

length. Assuming a light ray to be an electromagnetic wave of this kind, and taking the amplitude of H to be ·02 c.g.s. in strong sunlight, requiring the amplitude of E to be 6×10^8, or 6 volts per cm., and an electric current density of 240 c.g s., the maximum translatory force $-dP/dz$ parallel to z, is about 5 dynes per cubic cm. It is here supposed that the disturbance is simple harmonic, and that $v\lambda/\pi = 4 \times 10^5$, if λ is the wave length. The translatory momentum parallel to x is, in general, $2U_1/v +$ a constant independent of the time.

This motion of the medium parallel to z, not to be confounded with the internal motions of the disturbance, must react upon the electromagnetic wave. For, if v_1 be the z velocity (vector) the electric force induced by the motion is μVHv_1, and the magnetic force induced by the motion is cVv_1E; to a first approximation E and H are altered to these extents. If we compare these expressions with (11a) above, we see that $v_0N = v_1$ makes the electric and magnetic forces induced by the motion equal to the original electric and magnetic forces. This result of a uniform speed of motion of the medium in the direction of of propagation does not, however, mean more than the expression of the fact that if we travel with a wave, and at the same speed, the wave will appear stationary.

The size of v_1 depends upon the density of the medium, varying inversely with it. But v_1 is not likely to be anything but a very minute fraction of the velocity of propagation, and therefore negligible, unless we artificially increase the electromagnetic or magnetoelectric forces by passing a ray of light through a strong magnetic or electric field. Noticing that H = ·02 is quite small, we can greatly multiply the electromagnetic force by sending a ray across the lines of force of a strong magnetic field, whilst keeping its direction the same (along the ray). If, on the other hand, we send a ray parallel to the lines of force of the field, there is transverse electromagnetic force, and transverse motion produced, far exceeding the original in amount. Under such circumstances we might expect the effect of v_1 to be not negligible. These remarks, it will be noticed, rest upon the existence of the supposed stress.

(To be continued.)

SUBMARINE CABLES: THE COPPER RESISTANCE TEST.

BY A. E. BAINES.

Having examined a method by which the resistance of the gutta percha covering, or dielectric, of the cable may be determined, we now require to measure the resistance which the copper conductor offers to the passage of the current along it, for the reason that every unit of such resistance diminishes the quantity of the current in a given ratio, *i.e.*, $C = \frac{E}{R}$, where E is the electromotive force or initial pressure of the battery current, R the total resistance of the circuit external to the battery, and C the resultant current or quantity; resistance is therefore in the inverse ratio to conductibility. In the working of a submarine telegraph cable it is imperative that correct measures of this resistance should be periodically taken, because (1) the quantity of electricity required to actuate the signalling or other instruments at the far end of the line must be understood in order that the initial pressure of the sending battery may be correspondingly regulated; (2) in the event of a break the exact resistance of the conductor per knot must be known; and (3) frequent observation often enables the commencement of what may expand into a serious fault to be detected and provided for. Now, R is unalterable once the line is laid, but E is of course variable at pleasure. Before, however, we proceed with the technical details of the test which forms the subject matter of this paper, it would be, perhaps, as well to gain some further knowledge of the properties of *resistance.* If we consider running water, it will be found that the velocity of the water at the sides and the bottom of the stream is less than in the centre, and this lessened velocity is due to the resistance of the sides to the flow of water. In the case of water flowing through a cylindrical pipe the velocity of the flow is decreased by frictional resistance with the inner perimeter of the pipe, and is variable with the diameter of the pipe, the latter, like a copper wire, increasing in conductibility with diameter. Now, if this frictional resistance were not susceptible of alteration, the pressure (E) of the water would have, in order to even partially overcome it, to be increased. That is clear. Again, if we were to insert a poker in any fire, the amount of heat transmitted to the handle would vary in accordance with the length of poker (R) outside the grate, and the intensity (E) of the fire. If, therefore, we wished to make the handle hotter (or to increase C at the far end) we should have to do one of two things. Either to raise the temperature of the heat source (E), or to use a shorter poker, which would diminish R, and, as a necessary consequence, also increase C. If we wished to transmit a lesser amount of heat to the handle we should have to reverse these operations.

As regards conductibility, which is the converse of resistance, the specific conductivity of *pure* copper is taken at 100; but the copper used for telegraphic purposes is never up to that standard. It has a *lower* conductivity, and therefore a *higher* resistance. In many instances, however, its conductivity ranges from 85 to 95 per cent of that of the pure metal. To give an example of my meaning, the resistance of a wire of pure copper one inch in length, and weighing one grain, is ·001516 ohm at 60° Fahrenheit, and the resistance of any other wire of pure copper at the same temperature will be

$$= \frac{\cdot 001516 \times \text{square of length in inches}}{\text{weight in grains}}.$$

Weight being constant, the resistance of any wire varies as the square of its length, or inversely as the weight,

$$\therefore R = \frac{\cdot 001516 \times L^2}{W}.$$

Having obtained the theoretical resistance of a given wire, we have only to compare it with the actual resistance to find its conductivity.

Thus 100in. of wire weighing 1,440grs. should give a resistance of $\frac{\cdot 001516 \times 100^2}{1440} = 105{\cdot}27$ ohms; but if when tested it actually gave a resistance of, say, 110 ohms, its conductivity would be $110 : 105{\cdot}27 :: 100 : x = 95{\cdot}7\%$.

Having established the necessity of determining the resistance of the copper conductor of the cable, we will now proceed to see how this may be done. The operation is not a difficult one. We shall require, in addition to our galvanometer, battery, and testing keys, a combination of resistance coils or bobbins wound with fine, well insulated wire, and called a Wheatstone bridge or balance. This instrument has three arms, two of which are composed, generally speaking, of coils of 10,000, 1,000, 100, and 10 ohms—that is to say, each arm contains one of each of those coils. The third arm is variable, containing resistances ranging from 5,000 ohms to one ohm, there being a total of 10,000 ohms in that arm alone. Any or all of these coils can be cut out of circuit at pleasure by the mere insortion of a metallic plug in the spaces provided between each coil.

FIG. 1.

a b c resistance coils. $e_1\, e_2\, e_3\, e_4$ metal blocks to which ends of coils are soldered. *d* metallic plug with ebonite top. In Fig. 1 coil *a* is cut out of circuit; the current flowing from block e_1 through *d* (no resistance) to e_2. Coils *b* and *c* are in circuit, the current having to pass through them. Any or all of the coils can be cut out by inserting plugs as *d*.

Now, the Wheatstone bridge is nothing more than a pair of electrical scales, and for that reason, its simplicity, I have chosen the bridge method for illustration. There are, however, other ways of obtaining the resistance of a conductor. Now, having Fig. 2 before us, we will suppose that we have to measure the copper resistance of a cable (c) of 1,000 knots

Digitized by Google

in length, the approximate resistance of which is known, from tests taken during the manufacture, to be 10 ohms or so per knot. Let a and b be the two balancing arms, in each of which we will unplug the 10,000 ohms coil, because the nearer we get to the true resistance of c in each case the more accurate our results will be, and 1,000 knots × 10 ohms = 10,000 ohms. Let d be the third (variable) arm of the bridge, and G an astatic galvanometer connected as shown. The current enters at the fork β, and divides itself equally along the arms a and b to the points δ and γ, because the resistances of those two arms (a and b) are exactly equal. If a were greater than b, a proportionate excess of current would pass through b to γ, or

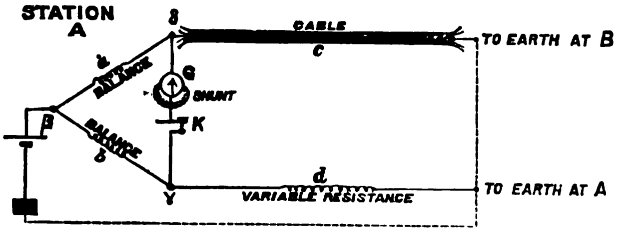

FIG. 2.

Note.—When $a=b$ and $c=d$ *no current will flow through* G. Resistance of G which gives greatest sensibility with known E.M.F. and weight of copper wire is $= \frac{(a+b)(c+d)}{a+c+b+d}$ . . . . ohms.

If balance cannot be obtained exactly, or, in other words, if difference of the fraction of an ohm in d is required to balance, then true resistance of d = lowest reading + $\left(\frac{a^0}{a^0 + a^0_1}\right)$, where a^0 is the deflection when resistance is too small and a^0_1 the deflection when resistance is too great. Example: with 11499 ohms in d the deflection (a^0) was four divisions to the right and with 11500 six (a^0_1) divisions to the left. ∴ $\frac{4}{4+6}$, and true d = 11499 + 0·4 = 11499·4 ohms.

were the reverse the case along a to δ, and the circuits a c and b d not being balanced there would be a transfer of current through G, either from δ to γ or from γ to δ, and the galvanometer would be deflected. Now, if the resistances of c and d are *also equal to each other*, no current will flow through the galvanometer from γ to δ or from δ to γ when the key K is depressed. Roughly speaking it does not matter if a and b = 10,000 ohms and c and d = 1 ohm. So long as $a=b$ and $c=d$ no current will pass through G, and a having been made equal to b, d must be adjusted by altering its resistance until the galvanometer registers no deflection upon the scale when contact is made at K. In practice, however, it very seldom happens that an adjustment can be made in submarine cable testing to the zero of the scale, owing to the presence of earth-currents, which, traversing the circuit, introduce a variable deflection which is altogether foreign to the conditions of a laboratory test. If we use a return wire from the resistance we are measuring to the earth side of d and battery, we can balance to zero; the current enters at the fork β, traverses the circuit, and returns to the battery without meeting with any disturbing influence; but it will be seen that if we insert another and smaller battery at any other point in the circuit, we shall get a deflection, due to the current from the second battery flowing through the circuit of G. If we know the number of divisions of the scale given by this extra E.M.F., we can work to that deflection and balance to it as to zero. In the case of a submarine cable it is not possible to use a return wire; the cable end must be put in connection with an earth plate at station B, 1,000 miles away, and we shall have, therefore, either to eliminate the deflections given by the earth current, or else, as is perhaps easier, to repeatedly observe and reproduce those deflections, the observations being taken both *before* and *after* the current is applied at A. Suppose, for instance, that upon closing K the earth current gave 150 divisions, proceed as follows:—Wait until the deflection is steady or has a measurable oscillation, open K and put on current sharply by depressing one lever of the battery key. Then close K by tapping. *If the earth current has not altered* and the deflection = 150, you have, presumably, a balance, but should observe the false zero again, opening K, taking off current and closing K, and should repeat the experiment with both zinc and copper currents half a dozen times to ensure accuracy. If the deflection = say 160, d must be adjusted. The extra 10 divisions may mean that d is slightly lower in value than C, or *vice versâ*, according to the sign of earth and battery currents. In such a long cable you must be prepared to find the false zero constantly shifting, and will have to take perhaps thirty or more readings before equilibrium is obtained.

The result in ohms given by d = the *total* resistance of the copper conductor of the cable, or of the whole length of 1,000 knots. To find the C R per knot, this quantity would have to be divided by 1,000.

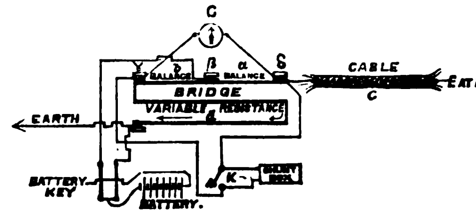

FIG. 3.

Practical connections at station A. First observe deflection given by earth current, if any, and work to that deflection in divisions of the scale as *false zero*. Put on current by depressing one lever of battery key quickly, and insert G in circuit by tapping K gently, if exact deflection given by E C is not reproduced observe false zero again, and repeat operation until it *is* reproduced. False zero must be observed *before* and *after* current is applied, to make sure that it has not altered during the preceding observation, short as it may have been. Make ratios of a and b as nearly equal as possible to resistance of C. That is if C = about 10,000 ohms, make a = 10,000 ohms and b = 10,000 ohms. If no earth current is present, adjust d until G gives *no deflection*. Use any convenient shunt to bring deflections within limit of scale, increasing the shunt resistance as equilibrium is approached. Subtract resistance of earth plate and lead from indicated resistance of d. Then corrected value of d = value of c in ohms. Divide this by length in knots for C R *per knot*.

Example: With a cable (x) of 1,000 knots in length a balance was secured when d indicated 11,500 ohms; a and b being 10,000 ohms.

Then $\frac{11500}{1000}$ = 11·5 ohms per knot, or, more properly,

$$\text{C R per knot} = \frac{d \text{ cor. for temp. and} - \text{res. of earth plate and lead}}{\text{length of cable in knots.}}$$

THE STORY OF A METEORITE.—Concluding his course of lectures on Saturday last, Prof. Dewar gave some interesting demonstrations of various laws connected with his subject. Having illustrated the periodic occurrence of showers of falling stars by means of a pendulum which left a track of fine sand, showing the intersection of the long elliptical orbit of the meteorites by the earth in its orbit, Prof. Dewar went on to give a most interesting experiment to demonstrate the attraction of the earth over small bodies coming within its atmosphere. He had at a height of about 12ft. from the floor a globe or imitation world, containing a magnet constructed by Faraday, and weighing 2cwt. With a spring tap he threw a light metal ball from one side to the other, the curve of its flight taking it near to the under part of the globe. When the ball went very near, it was drawn to the globe; if it passed too far away from the globe it was not arrested at all; if it went near enough for attraction but not near enough to be drawn up and held, it was twisted out of its course for a moment. A pendulum attached to the globe showed that the little ball also exercised attraction over the large mass. Some illustrations were given to show that the apparent approach of falling stars from one point was due to perspective, and that in reality they moved in parallel lines, and Prof. Dewar then experimented with spectrum analysis, exhibiting the characteristic colour bands of sodium, magnesium, iron, &c., in a spectrum, and then proving, by the combustion of a piece of a meteorite in the electric crucible, and by the same lines appearing in the spectrum, that those materials were contained in meteoric matter.

1885.

Leaving for a moment the work of private firms and public companies, we are now able to give a brief account of the progress during 1885 made by the

POST OFFICE TELEGRAPHS.—The chief event of the year in the Postal Telegraph Service is, of course, the reduction of the tariff, which came into operation on the 1st October. Its immediate effect, so far as the public were concerned, was to lower the initial charge for inland telegrams from one shilling to sixpence, the maximum of words, however, being at the same time diminished from twenty words, with an unlimited number for the addresses, to twelve words in all, addresses included. From every point of view, except perhaps the financial, the experiment has proved a success. As was predicted by the experts, the compulsory charge for the addresses, and the consequent curtailment of the telegram by more than one-half have caused no inconvenience to the public, who have quickly learnt to keep their messages well within the margin, or not far beyond it. As touching the telegraph service the traffic has been so greatly lightened by this universal shortening of messages that no difficulty at all has arisen in dealing with the additional work satisfactorily. On the whole, indeed, except perhaps at the very busiest period of middle day, the average delay is thought to be rather less now that telegrams are brief and more numerous than it was when they were fewer but much longer. At any rate, so ample had been the time allowed for the necessary preparations to meet the increase of traffic that no difficulty was experienced in coping with it either at the beginning of October or at any period since then. Naturally, the increase in the number of transactions has been very great, especially in local messages—that is to say, in messages addressed from one to another part of the same town. Notably this has been the case in London, where so complete had been the additional provisions made for local purposes that, contrary to past experience, senders find it saves time to send telegrams even over short distances within the metropolitan limits. It is too soon to pronounce decisively as to the financial prospects of the new tariff. Of course, there has been a large falling off in the revenue; but this was expected for a time, and has been taken into consideration by those who were responsible for the scheme. It has also to be remembered that the expense of delivery will be the same, or nearly the same, whether the message is short or long; but, on the other hand, the cost of transmission has been considerably reduced, two messages, or very nearly two, being now signalled in the time it previously took to signal one. On the whole, the Department and the public are to be congratulated on this important change, which has at length placed the British tariff on the rational basis long prevailing in other European countries.

The extensions and large additions to the existing lines effected in 1883-4 left little to be done in the year just ended; but some further wires have been erected, notably a new copper wire from London to Newcastle, an experiment which has proved the greatly increased working capacity of such lines. The electrical anemometer system for the Meteorological Society has also been completed. But the chief efforts of the past year were directed to the improvement and development of apparatus, the capabilities of which have been constantly expanding to meet the steadily increasing pressure of traffic. In Wheatstone simplex working alone the speed has in some instances been doubled; and for Wheatstone duplex working a proportionate increase of speed has been realised. To some remote points, such as the Islands of Jersey, Guernsey, and to Shetland, arrangements have been made so that in future any large accession of traffic on special occasions may be easily disposed of without additional wires. Many improvements in the construction and rearrangement of Repeaters on single, duplex, and quadruplex circuits have been effected with excellent results; and ordinary duplex working has been accelerated to not less than 50 per cent. On Wheatstone circuits a considerable advantage has also been gained by the introduction of a new form of Transmitter, and the substitution of single current keys for double current keys. Greater security against the effects of lightning has been insured by the adoption of a new form of protector in which mica is used as the dielectric. Some valuable improvements have been made in the pneumatic apparatus for the prevention of accidental stoppages; and a very large extension of this system with complete new machinery has recently been carried out in the Liverpool office. Pursuing the policy which has guided the Post Office from the very first no special efforts have been made to compete against private Telephone Companies for the custom of the public, and extensions in this direction have been carried out only at the solicitation of customers dissatisfied with the outside companies. But telephonic appliances are

Digitized by Google

continually undergoing improvements at the hands of the Post Office, especially in the matter of call signals, which are now rendered effectively independent of the negligence of the user. During the past year various inventions submitted to them have been tested by the Postal Telegraph authorities. Amongst these may be mentioned some new experiments with the Rysselberghe system on the Brighton Railway; experiments with telephone and telegraph lines between London and Leicester on the system recommended by Langdon-Davies; trials with Prof. Silvanus Thompson's valve telephone; trial of Villiers, Stead, and Co.'s microphone; and some careful experimental trials with Delany's multiplex telegraph system.

Passing from the Post Office work in Telephony, we may refer to that of the

CONSOLIDATED TELEPHONE COMPANY.—This company during the past year has been very successful as regards its manufacturing business, which, as our readers are probably aware, comprises the sole right to manufacture telephones for the United Kingdom, and also the sole right to manufacture telephones for export to all parts of the world. Very considerable orders have been executed for the United Telephone Company and its subsidiary companies, the Postmaster-General, the colonies, the River Plate Telephone Company (Limited), the Telephone Company of Austria, the Edison Gower-Bell Telephone Company, the Oriental Telephone Company, the Telephone Company of Egypt, and numerous private customers. The company has also done a large business in magneto bells, trembling bells, and switch-boards. New machinery has been purchased, consisting of screw machines, drilling machines, tapping machines, and lathes of the most modern and approved type, and this, no doubt, has tended to improve the general standard of the company's manufacturers.

A patent has been taken out for an improved form of magneto bell with toothed-wheel gear and novel cut-out. The magnets in this bell are most powerful, and are now coated by means of electro deposit, with a covering of brass to preserve them from rust. The toothed gear for working the armature is constructed on the most accurate mechanical principles, and is as near noiseless as any gear can be. The new patent cut-out is arranged so that when the handle is turned it has a movement of rotation imparted to it independently of the shaft, and causes a spring to be removed from the short-circuiting contact which it made when the parts were in their normal position, so that when the crank is turned it throws the armature in the circuit whilst the crank rotates, but as soon as the crank-handle is released the spring piece attached to the crank automatically returns to its original position, and touches a metal ring let into the side of the case, thereby short-circuiting the coil of the magneto armature.

The bell cases are made of specially selected and well-seasoned American black walnut, dovetailed by special machinery. The company guarantee this magneto bell to ring well through 15,000 ohms, and it can be adjusted to ring through 50,000 ohms. Improvements have been made in the consolidated telephone, for which the company holds the patent. Amongst them we may mention the substitution of an open for the closed top microphone. It not only overcomes the objection some people have of using the telephone immediately after another person, but it gives far better results, and has met with greater favour. A magneto call, with all the improvements above described, and its attendant saving of batteries, is fitted into the case containing the transmitter. Under the supervision of the Postal Authorities considerable improvement has been made in the Gower-Bell telephone.

A telephone, specially adapted for use in *wet* mines has been invented, and for some time past has been successfully used in Cornwall. A forward step in this company's divers' telephone apparatus has been made in the substitution of a Consolidated for a Blake transmitter, as the former, requiring no adjustment or attention, is of great service to those users who have not a sufficient technical knowledge to attend to the many requirements of the Blake instrument.

Another manufacture worthy of attention is a new pattern of switch-board which is compact, easily workable, and capable of being enlarged as the requirements of an exchange become greater. It is possible for one operator to connect three subscribers in a minute by means of this board.

On the whole, the Consolidated Telephone Company has made a great stride forward in the year 1885. Its subsidiary companies—the River Plate Telephone Company, the Telephone Company of Austria, and the Edison Gower-Bell Telephone Company—have each added largely to their numbers of subscribers, which, at the moment of writing, must be over 4,400, and are steadily and surely increasing each week.

The firm of FELTEN AND GUILLEAUME, of Mulheim-on-Rhine, near Cologne, Germany (for whom Messrs. W. F. Dennis and Co., of 101, Leadenhall-street, E.C., act as agents), have been fairly well employed in all their departments during the past year, another proof of the ingenuity and activity displayed by the firm, when it is considered that others of similar branches are absolutely lacking work and dismissing their staff. Messrs. Felten and Guilleaume have continued to supply heavy contracts of telegraph and telephone wire in their favourably known qualities of iron and steel, both for Continental and other Governments. In telegraph cables they have also had some good orders for underground and river work, cables of their manufacture having frequently been sent across the Atlantic during the year. However, the most noteworthy feature for the past year is the rapid progress Messrs. Felten and Guilleaume have made in the construction and manufacture of telephone cables.

The construction of suitable telephonic cables is one of the most important questions involved in modern electrical science. Great as has been the development of telephony throughout the whole world, it has been universally recognised that until recently its application was by no means perfect. With the steadily increasing number of subscribers in large towns it has become impossible to place the wires required to connect the subscribers. When only a few subscribers were connected to the exchanges, it was an easy thing to conduct the wires over the roofs, in the same manner as telegraph wires are frequently put up, by means of porcelain or glass insulators fixed on poles. But when thousands of wires are to be put up and made to converge into one central point, this easy system is no longer applicable, and the only substitute possible is that of cables, either underground or aerial. Hence, the universal cry for telephone cables which has been a prominent feature in all our electrical papers for several years past. Now, it is easy to combine even a very large number of insulated wires into cables, but to construct a telephone cable that will work is a matter of considerable difficulty, owing to induction, retardation, and other phenomena; but Messrs. Felten and Guilleaume have succeeded in at least largely overcoming these difficulties, as will be seen from the fact that during the past year they have manufactured and laid considerable quantities of telephone cables, which have not only answered, but exceeded all expectations, both in Germany and in other countries, including England. Thus, at the end of 1884, Messrs. Felten and Guilleaume had put up at Munich about 2,800 yards of aerial telephone

Digitized by Google

cable suspended by means of a carrier wire. The Royal Bavarian Telegraph Department pronounced this cable (consisting of 27 conductors) as "free of induction and retardation," and "giving entire satisfaction." The result of this experiment was a further order for about $4\frac{1}{2}$ miles of 27-conductor telephone cable, to be laid underground at Nuremberg. This was done in June, 1885. The cable, laid in iron casings, was put in operation in August, with the same good results, the Royal Bavarian Telegraph Department having since expressed their entire satisfaction, and acknowledged the "excellent quality and efficiency" of these cables. During the same time the Imperial German Telegraph Department, having obtained similar good results with about seven miles of 27-conductor underground telephone cable of this company's manufacture, decided on another order of about nine miles of the same cable, which has since been executed by the firm. The department certifies that the cables give "every satisfaction," and that the "excellent results" obtained with the first lot have decided the second order.

The Copenhagen Telephone Company reports in June, 1885, that having had in continual use for six months without disturbance or accident a total length of about $1\frac{1}{2}$ mile of Felten and Guilleaume's aerial telephone cable, and this experiment having had the most satisfactory results, they have decided to order another twelve miles of 27-conductor telephone cable, the major portion of which would be laid underground. These twelve miles were laid in October, and are now, after having been in operation for some time, pronounced to be a complete success. The cables are so arranged that up to $5\frac{1}{2}$ miles of cable are spoken through, but sometimes about six miles of ordinary line are connected to the ends of the cable, so that it often happens that about 12 miles of cable and wire are spoken through. Nevertheless, the transmission of voice is excellent. A further addition of fresh cables to the system is planned.

Mr. Madson, director of the Copenhagen Telephone Company, recommends Messrs. Felten and Guilleaume's cable as "most efficient, and satisfying all conditions of the telephonic service." A further length of about 7 miles of 27-conductor telephone cable has been supplied in the latter part of the year for the Swiss Telegraph Department; also about $3\frac{1}{2}$ miles of 52-conductor cables for a Canadian Telephone Company, and last, not least, about $1\frac{1}{2}$ mile of 27-conductor cable for a telephone line through the newly-finished Mersey Tunnel, all of which gave entire satisfaction. All these cables are lead-covered, having a double impermeable but light lead-covering, and are insulated with a compound of their own, which gives the highest possible insulation, and renders the cable uninfluenced by heat. In using other kinds of telephone cables it has been observed that when a telephonic line was composed partly of such cables and partly of open aerial wire lines, the retardation was so strong as to make speaking through such lines nearly impossible. At the request of the Imperial German Post Office experiments have been made lately with Messrs. Felten and Guilleaume's telephone cables on a line composed of about six miles of their cable connected with thirty miles of open wire line. These experiments have proved that even on such long lengths retardation was practically absent, and that these cables answer perfectly for all telephonic lines.

Continuing our remarks upon Electric Lighting, we come to the work carried out by the ANGLO-AMERICAN BRUSH CORPORATION, which during the past year comprises much of importance as bearing upon the application of electricity to various industries in the future. The thorough manner in which its installations have been designed and carried out has contributed in no small degree to the revival of confidence in electric lighting which is now beginning to be felt by the public. Much has been done during the past twelve months towards perfecting the various kinds of electrical apparatus manufactured by the corporation, who hold the unique position of being the only firm in this country supplying both high and low tension dynamos, and arc and incandescent lamps manufactured by themselves. The exceptional facilities thus offered to improvement in combinations of plant used in every branch of electric engineering have been thoroughly utilised by the company. The high reputation which the Victoria dynamo has earned ever since its practical introduction has during the past year been fully maintained. This machine has been extensively employed by the home and foreign Governments for both naval and military purposes, and it is now a well-recognised article of commerce. The various other accessories to electric lighting, such as projectors, signalling, and torpedo search apparatus have been largely used.

The introduction of slow speeds for both engines and dynamos, for which the facilities offered in this direction by the construction and form of the Victoria dynamo have been in a great measure responsible, has resulted in reliability of working on board ship, which is being recognised throughout the mercantile marine, and has imparted an additional impetus to the electric lighting of passenger steamers. Considerable attention has also been paid by the above company to motor work, and motors of large powers have been supplied both at home and abroad to work in conjunction with Brush machines of high tension to transmit power over long distances. The Brush dynamo and arc lamp, in which important modifications have been made, still continue to hold their own. It is hoped that ere long a practical and extended application of their use may be seen in the metropolis on a scale somewhat like that adopted across the Atlantic. Foreign contracts have constituted no inconsiderable portion of the Brush Company's operations during the past year; but among home firms to whom, or localities where plant has been supplied or installations successfully carried out may be mentioned the following:—The Central Station at Glasgow, and the Grangemouth Station and Docks, for the Caledonian Railway Company; the Waverley Station at Edinburgh, South Kensington Museum throughout with the new Brush-Sellon lamps; Holloway Sanatorium at Virginia Water, the Woking Convalescent Home, Messrs. Ritchie and Co.'s Mills, Stroud; the Duke of Bedford's yacht "Northumbria," the yacht "Christine," the Newbottle Colliery, and others. Many similar contracts are in hand for the coming year, amongst others the lighting of a portion of the Colonial and Indian Exhibition.

The past year has not been an uneventful one for this corporation. Besides the completion of important schemes initiated with the view of extending the scope of the company's business and influence, it has been made evident from the extensive and successful work carried out that during the past year the company has, in a commercial sense, turned the corner. The past year has also witnessed many important changes in the composition of the board of directors. In the early spring the company lost, by the death of Mr. Ladd, the services of one of its original directors and the co-operation of one of the earliest workers in practical electric lighting. As a result of the amalgamation with the Great Western Electric Light Company, the corporation secured the services of Mr. Braithwaite as a director, and later in the year Lord Sudeley

Digitized by Google

and Major-General Webber, C.B., accepted seats at the board, the latter doing so in the capacity of managing director.

Our notes upon the work of 1885 have run to an unusual length, but we must keep the concluding portion for another week.

CORRESPONDENCE.

THE ECONOMICAL DISTRIBUTION OF CURRENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In one of the lectures by Prof. Geo. Forbes, printed in *The Electrician* of November 6th last, it is stated that the "three-wire system" of distribution of current is not so economical as has been given out here in America—that is to say, that there is no such saving as that of 62 per cent. of the copper required for the "two-wire system."

Being connected with one of the Edison companies, I feel it necessary to contradict that statement and prove it to be otherwise; and being an Englishman myself your readers need not take this as a mere defence of a "purely American idea," but a truthful representation of facts as they ought to be understood.

Putting aside the "three-wire system" for the moment, there is a very simple rule in regard to the advantage of increasing the potential in saving of copper. It is that the quantity of copper required to transmit a certain amount of electrical power (watts) at a given loss (or per cent. of loss) varies inversely as the square of the potential.

In the three-wire system we have an extra middle wire; but assuming the current is balanced, neglect this, and for doubling the potential we require, according to this rule, only 25 per cent. of the copper required for the two-wire system. Now, add one wire equal to one of the other two—that is, add 50 per cent. to this 25 per cent., or $12\frac{1}{2}$ per cent., this makes $37\frac{1}{2}$ per cent. of the copper required, or a saving of $62\frac{1}{2}$ per cent. This can be still further increased to 69 per cent. by using a one-half sized wire for the middle or neutral wire, which is quite sufficient.

For an example take 100 lamps of 90 ohms each, and on the two-wire system first. Then the resistance of all these lamps in multiple arc would be $\frac{90}{100}$ or ·9 ohm. If, now, we like to lose 10 per cent. in the line to the lamps (assume the lamps to be all at the end of the line for simplicity), the resistance of the line will be of course 10 per cent. of the total resistance of the circuit, or ·1 ohm. The total resistance, then, of the line and lamps is 1 ohm.

On the three-wire system there would be two sets of 50 lamps in multiple arc, each 50 would have a resistance of $\frac{90}{50}$ ohm (90 ohm lamps), or 1·8 ohm, and the two sets in series would be 3·6 ohms, or four times the resistance of the lamps arranged on the two-wire system. A line to lose 10 per cent. of the potential, therefore power, on this circuit would be ·4 ohm, making a total resistance of the circuit (line and lamps) of 4 ohms.

Instead now of having two mains of ·1 ohm we can use two of ·4 ohm, which must, therefore, only be one quarter of the section of the others, and so only 25 per cent. of their weight. Now add a middle wire, or $12\frac{1}{2}$ per cent., and we arrive at the same conclusion as before.

Any one acquainted with Ohm's law can make this out by putting it on paper, though I can easily understand that at first sight it may look very much as if reducing the current to one half you require one half the section of wire.—Yours, &c.,

New York, Dec. 31, 1885. HENRY E. WALTER.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am glad your correspondent, Dr. Stone, has given vent to his thoughts on this subject. He is unknown to me, but the idiosyncrasy of his mind is common to that of many eminent writers on electricity. When a series of facts about electricity are laid before them, they see those of the facts which are in favour of their theory of electricity, but they are blind to or will not admit into their minds the facts which tell against their theory of electricity.

My letter as printed in your pages occupied twenty-five lines. One of these has alone made an impression on Dr. Stone's mind, "the carpet and the bare feet," whereas the last thirteen lines of my letter are about an electrical phenomenon which has not on any previous occasion been laid before the public in print.

Will Dr. Stone be so good as turn his attention to it and give his explanation of it through your pages?—Yours, &c.,

JAMES JOHNSTONE.

8, Merchiston-park, Edinburgh, 9th Jan., 1886.

THE SCIENCE OF ELECTRICAL ENGINEERING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great pleasure the excellent remarks of Mr. Walker in the last issue of your esteemed paper.

Allow me to say one word with regard to "There is no mystery about electrical engineering."

A few days ago I was told by the *manager* of the works I am in not to tell the men too much, as there was nothing in electrical engineering; any one could pick it up.

The same manager said to a young fellow who wished to go outside and learn the installation work, "There is nothing to learn; all they (those engaged on installation work) know, you can pick up in half an hour."

The above facts speak for themselves, and need no comment of mine.—Yours, &c.,

A YOUNG ELECTRICAL ENGINEER.

RESISTANCE AND CONDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Will you, or some of your readers, kindly acquaint me with the difference in resistance and conduction between a solid bar and a hollow cylinder of copper, both being of the same length and diameter? As regards the thickness of the cylinder any convenient numbers will do. On the one hand I am told that electricity flows *over a surface*, and on the other that conductivity is in the inverse ratio to sectional area. These two statements rather confuse me.—Yours, &c.,

TYRO.

THE DYNAMO AS A GENERATOR AND AS A MOTOR.*

BY W. M. MORDEY.

During the last few years an immense amount of attention has been given to everything relating to theory and practice of dynamo machines. So thorough has been the study of the problems connected with these machines, which are of a character to appeal both to the physicist and the practical constructor or engineer, that it is now not difficult to lay down, in a fairly complete form, the laws governing their action, and the rules and principles under which they should be constructed, although three or four years ago much confusion and uncertainty existed as to what was best in dynamo construction.

But in electric motors the case is very different. While it is easy to name physicists and constructors in considerable numbers who hold clear and correct views on the subject of electric generators, it is by no means easy to find definite and correct explanations of what is right and what wrong in regard to the allied subject of electric motors.

And on no point does there appear to be greater uncertainty than on that of the analogies and the differences between the two machines. For instance, while it has been proved beyond question that in dynamos the most economical and best working conditions are obtained by employing field-magnets of great magnetic strength, and armatures which are relatively

* From the *Phil. Mag.* for January.

Digitized by Google

very weak magnetically, the only definite assertion within the writer's knowledge given with authority on this point asserts the contrary to be the case with motors—that the fields should be relatively much lighter and weaker than the armatures*.

Again, what can be more striking than the great and known difference between dynamos and motors in respect to the very important matter of efficiency! Almost any modern generator will give a return in the form of electric energy of 90 per cent. of the mechanical energy expended in it, and a useful yield of over 80 per cent. in its external circuit. In the case of the best generators this is a considerable understatement of the working conditions. With electric motors, on the other hand, one has to be contented with a much lower efficiency. The energy supplied to them is severely taxed in the process of conversion. Motors frequently yield, as mechanical energy in a useful and available form, only 30 per cent., and seldom more than 60 per cent., of the electric energy absorbed.

The reversibility of the dynamo, or its ability to work either as generator or motor, has been spoken of as one of the most important discoveries of late years (the great physicist credited with the expression of this opinion having apparently overlooked the fact that Pacinotti made his famous machine as a *motor* in the first place). But the fact that a given machine which will work well and efficiently as a dynamo, will not work so economically when its action is reversed and it is made to act as a motor, is a proof that the reversal is accompanied by some radical change in its action. This difference, where it is noticed at all, is generally sought to be explained by an assertion or a supposition that having been designed and made for one purpose, it was therefore not suitable for the other. No satisfactory explanation, as far ss the writer is aware, has been given of the cause of this lower efficiency of motors, or, in other words, of how the missing power is expended. In what particulars a good motor should resemble a good dynamo, and in what they should differ from one another, are also interesting questions of great importance which await answers.

The writer having, with Mr. C. Watson—who is his assistant in the works of the Anglo-American Brush Electric Light Corporation—given some attention to the matter from a practical point of view, a great necessity was felt for some foundation on which to work, similar in character to the broad general principles which serve to guide the practical constructor of dynamo machines. In the search for such general principles, all those ways of considering the actions which depend on the idea of magnetic poles in the armature were abandoned, and the conclusion was arrived at that the armature should have no polar action whatever, that the iron of the armature should have only the function of a conductor of lines of force and that the power of the motor should be due to the simple action between the lines of force of the magnetic field and the armature wires conveying currents at right angles to those lines of force. This mode of regarding motor action is convenient on several grounds, and leads to certain conclusions, which, if correct, form substantial bases for practical construction. Thus the armature, instead of being as hitherto considered as a strong electromagnet placed in the field of another electromagnet, is to have its electromagnetic functions reduced as much as possible, or preferably suppressed altogether.

The field is to be very strong.

As with such an arrangement there is no polar effect in the armature except that due to the direct magnetic induction of the field-magnets, it follows that the maximum power is obtained with any given current when the brushes occupy an absolutely neutral position, or, in other words, when there is no "lead" and no distortion or rotation of the field. These conditions do away with the most troublesome and prolific cause of the sparking at the brushes, which is so often an objectionable feature of most electric motors.

But by working backwards in this way it was seen at once that the conditions which seemed to be best for a motor were precisely those which the would-be designer of a perfect dynamo would set before him as his goal.

* Profs. Ayrton and Perry, "Electromotors and their Government," *Journ.* Soc. Teleg. Eng. and Electricians, March, 1883.

Certain perfect analogies had been arrived at. In both dynamos and motors, according to this briefly-sketched view:—

(1) The field should be a very strong, the armature a very weak electromagnet.

(2) In both generators and motors "lead," distortion, or displacement of brushes or of magnetic field is wrong, and is to be avoided by attention to (1).

Whatever "lead" there may be in either case, there is this difference, that in dynamos this "lead" is in the direction of rotation; in motors it is in the opposite direction, as the course of the current through the armature is reversed, but the field is the same.

(3) In both generators and motors absence of sparking at the brushes depends mainly on the conditions of (1) being complied with.

(4) Reversal of rotation. In neither generators nor motors is movement of the brushes necessary.

But having got so far, a little consideration suggested the probable existence of another analogy. Since a dynamo having the above theoretically perfect form and action, with a constant field would produce a constant electromotive force if run at a constant speed, independently of the load or amount of current generated, a motor constructed on the same principles and having a constant field, if supplied with energy at a constant difference of potential, should run at a constant speed, independently of load.

If this should prove to be a true analogy, a simple means of obtaining results of great use in the practical application of electricity would be obtained—results which have been sought in many directions, more or less complicated, without any great success.

By permission of the Anglo-American Brush Electric Light Corporation experiments were carried out in the testing room of their works with a Victoria dynamo. The results ultimately obtained, which are given in the following tabulated account of the experiments, and in the curves plotted for them, show that this fifth analogy is as true as the preceding ones, a constancy of speed being obtained which was very remarkable —even when the load was increased, until much more than that which as a generator was usually considered the full working current was traversing the armature.

Two sets of readings were taken, working up to about the same current in each set, but with the potential-difference of the supply different in the two cases, as stated. The field was of the same strength throughout. The load consisted of another Victoria dynamo driven through a modified White's transmission-dynamometer, the work being varied as required by altering the external circuit of this dynamo.

Digitized by Google

At first it appeared that the counter electromotive force of the motor was dependent neither on speed nor strength of field, as the latter was constant and the former very nearly so, while the current rose with the work; but calculation showed that this was not the case, indeed it could not be so.

Let us call the counter electromotive force e, and the loss of potential caused by the resistance of the armature e_1, and the difference of potential at the terminals E. Then

$$e + e_1 = E.$$

Calling the current C, and the resistance of the armature R, we know that

$$e_1 = C R.$$

The resistance of the armature of the motor in question was ·027 ohm, which we will call ·03 in order to make some allowfor the effect of heating.

In the first and last readings of the second set of tests (curve B) we have, therefore, the following conditions:—

Speed.	e_1.	e.
680	·87	99·13
660	3·75	96·25

Now $$\frac{680 \times 96{\cdot}25}{660} = 99{\cdot}13.$$

From which it appears that the counter electromotive force was exactly proportional to the speed, as is to be expected where the field is constant and the magnetic distortion *nil*.

The other cases do not work out with the same accuracy. The results are, however, quite within the limits of error inseparable from the rather rough conditions of these workshop tests.

One other fact may be pointed out in connection with these tables of results and curves. In the case of dynamos working with a constant field, the output with the same current is almost exactly proportional tc speed, as the E.M.F. is also simply proportional to speed. So with the motor, the speed is proportional to the E.M.F. of supply; and the work, with the same current in the two cases, is simply proportional to speed, therefore to E.M.F.

With regard to the theory alluded to above, that in a motor the fields should be much weaker and lighter than the armature, it may be pointed out that in this, as in the other points mentioned, there is a real analogy between motors and generators, inasmuch as, according to the views briefly expressed in this note, such a motor, although a bad one from most points of view, would have a certain advantage in that for its weight it would do a good deal of work. Similarly, dynamos may be, and have been built, which, although far from efficient and reliable, will give a large output for their weight. Their construction is, however, scarcely to be recommended on this ground, except, perhaps, under very exceptional circumstances; and they, as well as the motors constructed on the same lines, appear to be instances of a mistaken apprehension of elementary principles.

Having briefly traced the analogies between generators and motors thus far, the subject may be dismissed for the present with the remark that a further consideration of the matter serves only to reveal the fact that in almost every phase of their actions the two machines afford further opportunities of a direct comparison.

Turning now to the question of efficiency alluded to above, it is evident that there is some important cause of loss or waste of energy in electric motors which is absent in generators. This has always been a kind of *lacuna* in the explanations of the action of motors; and in order to localise the loss and to ascertain its cause, the several possible sources of waste were carefully considered. These are:—(*a*) Friction at the bearings, air-friction, and friction of the brushes against the commutator. (*b*) Loss of energy in heating the armature and field conductors, and a certain loss due to self-induction. (*c*) Loss by the production of eddy-currents in the iron.

Now it is evident, especially with a generator or motor having the qualities sketched above, that at the same speed, and working with the same currents in its conductors, the losses under (*a*) and (*b*) must be identical, whether it be working as a generator or as a motor. And as with such conditions its efficiency as a motor is lower than as a generator, the cause of the loss must be sought under (*c*), *i.e.*, the eddy-currents in a dynamo must be less than in a motor, all other conditions being the same. And such is the case, the explanation arrived at by the writer and Mr. Watson being a very simple one.

In a dynamo the rotation of the armature causes eddy-currents to be generated in the iron core, in the same direction as in the conductor proper with which the core is surrounded. Of course, as the armature is always more or less subdivided or laminated in a direction at right angles to the lines of force, any circulation of currents round the core is avoided; but local currents, which are aptly called eddies, are set up, and, taken as a whole, these eddy-currents on the outside of the core are in the same direction as the current flowing in the copper conductors.

In an electric motor, however, the eddy-currents and the currents in the copper conductor are in opposite directions; as, although the E.M.F. set up in the conductor is in the same direction in a motor as in a dynamo, the current in the former is forced through the armature in a direction contrary to the E.M.F., or opposite to its course in a generator. According to the laws of induction, therefore, it will be seen that while in a dynamo the two sets of currents, those in the iron and those in the conductor, tend to oppose and to reduce one another, in a motor they act in such a manner as to mutually assist each other. Thus, with the strength of field, the current in the conductor, and the speed the same in the two cases, it will be seen that in a motor the eddy-currents in the iron core of the amatures will be greater than in a generator, and therefore the heat-loss in the former will be more than in the latter. There is little doubt that this is the cause of the lower efficiency of motors than of generators; and it points to the advisability of giving even greater attention in the former to those principles which are well understood for the reduction or elimination of eddy-currents.

DYNAMO TESTS.

(Continued from page 176.)

Calorimeter Calibrations.—The calorimeter has been described. In making the observations, the time the mercury crossed each half degree or centimetre of the thermometer was taken as the mean of the times of crossing the tenths before and after the division, and the division itself. In calculating the water equivalent of the calorimeter, the weight of the shaft was multiplied by the specific heat of steel; that of the cylinder by the specific heat of copper, and the weight of the glass and wire by their specific heat. For steel, the value of the specific heat was assumed to be ·1110, and that of copper ·0940.

The principal correction to be applied is due to radiation. The other corrections are for rise of temperature from stirring, for the part of the thermometer stem in the air, and a small one for weighing in air.

The coefficient of radiation was determined by noting the rate of cooling, the calorimeter being slowly stirred. Experiments gave

Difference between air and calorimeter,	10° C. 1	coefficient,	·00154
,, ,, ,, ,,	5° C.	,,	·00150
,, ,, ,, ,,	0° C.	,,	·00149

Before the experiments, and for the determination of the radiation, the cylinder was carefully polished.

The correction for stirring was determined by bringing the calorimeter to exactly the temperature of the air, and then turning the wheel belted to the pulley on the shaft three times per second. The rise of temperature was ·02° in five minutes. For the smaller velocity used in the later experiments, the heating was assumed to vary as the cube of the velocity.

The correction for the temperature of the stem was taken from

$$c = {\cdot}000156\, n\, (t - t')$$

Probably the greatest source of error in the calorimeter experiments was the superheating of the wire in the water. Using platinum iridium wire varnished, with a smaller current than was generally employed in these experiments, Mr. L. B. Fletcher calculates* that the superheating is about 2° C. But in the measurements described above the wire was bare and the flow of water past it very much faster than in Mr. Fletcher's work. In the last two experiments a rise of 2° C. would cause an error of less than one-tenth per cent., so it is probable that they are not much affected by this source of error.

* American Journal of Science, July, 1885.

It is also possible that there was conduction through the water. The calorimeter was carefully cleaned before each experiment and distilled water used. If such an effect existed, it would be in an opposite direction from the superheating.

The usual range of temperature was 10° C. ; in the experiment given it was a little over 6°.

Besides the regular calibrations, the constant was calculated after each test, from the potential at the extremities of the German silver "dead resistance," the current being measured by the current galvanometer, and the resistance measured by the bridge. The following partial list of calibrations excludes measurements made in this way. It includes the time during which most of the tests were made—from June 11th to June 23rd :—

22	1·843	1·843	Voltameter.
23	1·843	1·843	Voltameter.

For the Edison Nos. 5 and 10 dynamos, the potential galvanometer was in the same position as when used for the duration test of lamps, in a room at some distance from the test house. Before the machine was run on the partial loads, the galvanometer was taken to pieces, the coils rewound and soaked in paraffin, and the stand of the tube carrying the suspension more firmly secured. A beam, which pressed against the wooden pier, was also cut away. After this, the constant did not vary, the calibrations rarely differing more than one-tenth per cent. from the constant used.

(To be continued.)

THE LATE SNOWSTORM AND OVERHEAD WIRES.

At the meeting of the Metropolitan Board of Works on the 8th inst., mention was made of the serious consequences arising from the failure of the fire alarm telegraph circuits last week owing to the destruction of overhead wires by the snow. It was also resolved that the Works Committee should "inquire and consider as to the facts relating to the recent accidents to overhead telegraph and telephone wires, and the danger to the public therefrom, and to report thereon, and as to the necessity of any proceedings or future legislation on the subject, and that the surveyors to the vestries and district boards be requested to supply the Board with information which they have." On the motion of Mr. Selway, the report of the Works and General Purposes Committee was received. It recommended that the United Telephone Company be informed that the Board, having again given consideration to the matter of the erection of their telephone poles, are unable to depart from their previous decisions, declining to accede to the Company's requests.

On this subject the *Daily Telegraph* remarks : "In the course of the parliamentary investigation last year, Lieut.-Col. Haywood, engineer to the Commissioners of Sewers, stated that within the last ten years 320 wires had been carried across Moorgate-street and 240 across Leadenhall-street. In Cannon-street there were seven cables and 360 wires, and in Fleet-street from one spot in Ludgate-circus one could count 142 wires and two cables. Taking the mean roughly, this number was at the rate of 1,000 wires per mile. This average has since then been exceeded. With regard to the durability of a line there seems to be some doubt, but it is asserted that the risk is increased in proportion to the number of wires.

Digitized by Google

At present there is no authority with legal control over the telephone companies. In the case of the Wandsworth Board of Works against the United Telephone Company, it will be remembered that the Court of Appeal decided that so long as the wires were not proved to be a nuisance, that is to say, to be dangerous to life or property, the local board had no veto upon the erection of a wire across the road. In this respect legislation is said to be wanting. Lieut.-Colonel Haywood offered the opinion that there ought to be in all the more densely-inhabited parts of the metropolis, large subways, such as the Corporation constructed in the Holborn-viaduct, and in some of the side streets, in which not only telegraph wires, but gas and water pipes, and those of the electric lighting companies should be placed. With respect to the last named, it is quite certain they could not be tolerated in proximity to the telegraph cables. It was entirely owing to the fact that the bulk of the General Post Office wires in the London district are now conveyed underground that there was not a complete breakdown during the snowstorm and since. At points and in some of the suburbs where open lines are in use, the fall of telephone wires rendered them useless, but no such interruption occurred in the metropolis generally. On Wednesday there were actually transmitted from one part of London to another 13,936 messages, the largest number ever despatched in one day, the average since the introduction of the sixpenny rate having risen to nine or ten thousand from five or six thousand."

The Chairman of the Parliamentary Committee above referred to, Mr. G. W. E. Russell, writes to *The Times* as follows :—

"Sir : In Mr. Beachcroft's letter about overhead wires he refers to the report presented by the Select Committee, of which I was chairman. Permit me to say a few words in self-defence. After a careful examination of exhaustive evidence, the committee did not feel justified in recommending the total discontinuance of overhead wires. But, in the draft report which, as chairman, I proposed to the committee, I urged the following precautions :—All overhead wires should be subject to proper supervision. Overhead cables should not be permitted. Where more than ten wires are run along a line, the local authority should have power to compel them to be taken underground. The local authority should also have power to regulate the length of span and other conditions necessary to secure the safety of the public. No power to pass and keep wires over private property without the consent of the owner or occupier should be given to any company or private person. All owners of land or occupiers of houses should have power, by notice to the local authority, to cause the removal of wires crossing their property and belonging to any company or private person. No company or private person should have power to make attachments to houses or buildings without the consent of the owner or occupier. By-laws for the regulation of all wires as to substance, length of span, durability, &c., should be made for the whole of London by the Metropolitan Board of Works. Every wire should be registered with the local authority, and all ownerless wires be removed. The duty of inspecting wires and maintaining them in proper order should devolve on the owners, who will be responsible for the results of neglect. These precautions were rejected by the majority of the committee, and a report was presented, inconsistent, in my judgment, with the public safety and the rights of private property."

Commenting on the above letter Mr. G. Layard, of 5, Fenchurch-buildings, suggests that if those local authorities who are desirous of obtaining more ample powers for dealing with these wires would at once take steps (before the circumstances are forgotten) to obtain and record the particulars of all which have fallen in their districts during the last few days, whether resulting in injury or not, they would accumulate a mass of evidence which would be readily available for securing the desired result.

The *Saturday Review* thinks that "If only every winter had its snow, and plenty of it, there were hope for the long-suffering Londoner. Then, perhaps, the myriad telegraph wires that threaten the devoted neck of the passenger might be carried underground. Of course nothing will be done at present, as not even an omnibus horse was injured by the wires that, in some instances, hung across the streets. When some one in the Post Office is strangled or beheaded, the Post Office authorities will, perhaps, consider the matter."

Messrs. Beal, Son, and Chartres write to the *Daily News* as follows :—"We had so narrow an escape of our lives here yesterday (6th inst.) that it is as well to record it as a protest against overhead wires. A large skylight covers one of our offices, and owing to the breaking of the connection of the trunk wires portions of the parapet of the adjoining house were hurled through the skylight of a weight sufficient to have killed anyone seated therein. No one for the instant was in the room, but the chairs in which they would have been seated bear evidence of the force at which the stone and brickwork descended. The company have acknowledged their liability, but the moral we venture to draw is 'No more overhead wires.'"

A great number of narrow escapes from falling wires have been reported ; but although much damage to property has been done the only serious cases of personal injuries appear to be that of the man in Clerkenwell, whose eye was entered by the broken point of a wire, and another man at Peckham, who was seriously hurt by the fall of a telephone pole. Most of the breakages occurred in early morning, before street traffic commenced, and to this cause undoubtedly we may attribute the remarkable fewness of personal casualties.

MAGNETISM.

BY WILLOUGHBY SMITH.

(Concluded from page 178.)

Figs. 1, 2, and 3, in Diagram VIII., show the results obtained with a rod, square plate, and a disc of iron. The arrows indicate the

DIAGRAM VIII.

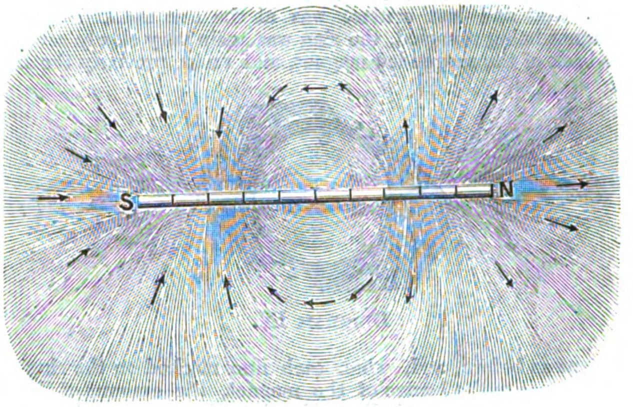

FIG. 1.

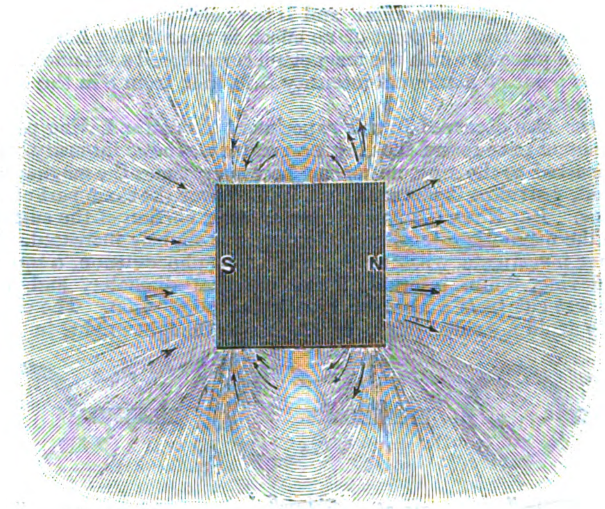

FIG. 2.

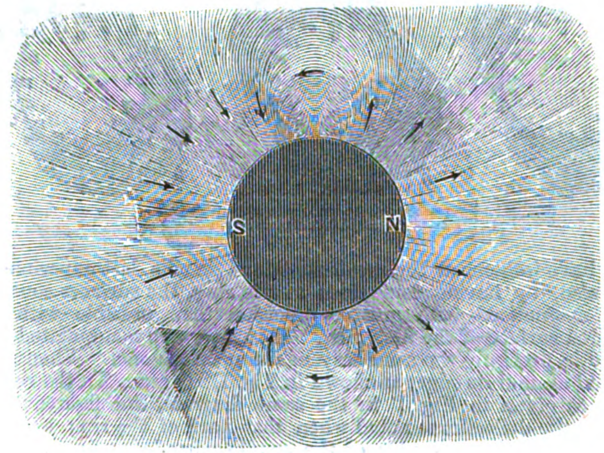

FIG. 3.

direction assumed by the magnet in each position in which it was placed relatively to the iron, which in each case remained stationary. The results are very similar to those obtained by the single mirror reflecting magnet ; and, as that arrangement was more easy

of manipulation and accurate in measurement, it was again used for all similar experiments.

If permanent polarity, however slight, has been communicated to either iron or steel in any form by any known means, the intensity and direction of its polarised lines of force can be measured. A ring made from a steel rod ·375in. diameter was hardened in oil and then mounted on a wooden disc, through the centre of which passed a small spindle, to allow of the ring being easily revolved vertically at right angles to the small suspended magnet, the distance between the two being 18in. No effect was observable on the magnet, although the ring was revolved several times. The outer surface of the ring was marked off into eight equal parts. One of these lines was marked S, and magnetism was then imparted to the ring as follows. The south pole of a powerful permanent steel bar magnet was placed on that part of the ring marked S, and the ring was then slowly revolved until its circumference had passed *once* under the south pole of the magnet, so that the point of first and last contact was at the line marked S. The bar magnet being removed, the ring was again very slowly revolved at the back of the suspended magnet, and under precisely the same

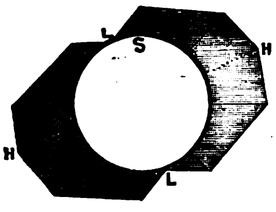

DIAGRAM IX.

conditions as before, and, when each line marked on the ring was directly opposite the centre of the magnet, the amount of the deflection of the magnet, as indicated by the reflection from the mirror, was noted. Diagram XI. shows the results obtained ; H indicates the position of greatest effest, and L the position of no effect. It will be seen that the point of no effect is near to the line S, that being the place at which the magnetism commenced and ended ; and that the point of maximum intensity is farther from S in the opposite direction.

It was also observed in this experiment that after having passed the magnet once round the ring, no greater magnetic intensity could be imparted to the ring, no matter how many times the magnet was applied, providing it was each time applied over the same part of the surface. But if it were passed over another portion of the surface, then the magnetic intensity of the ring was slightly increased. To further investigate what to me was a new phenomenon, a square-edged ring, 8·5in. internal, 9·5in. external diameter, and ·5in. thick was cut from a plate of best "Lowmoor" iron. The object was to avoid a welded joint, which it was thought might, in some

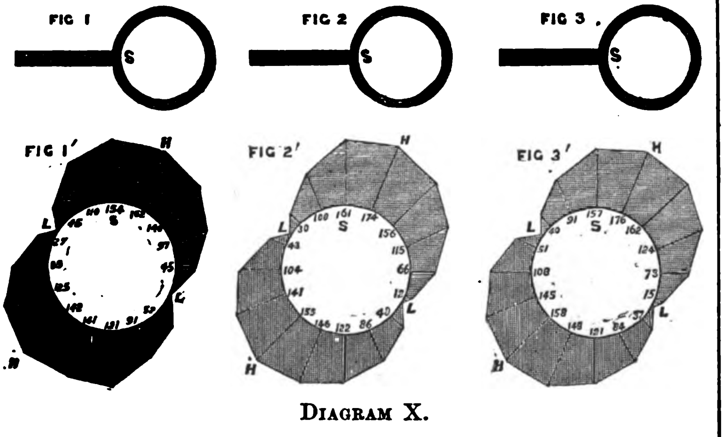

DIAGRAM X.

way, have influenced the results obtained in the last experiment ; and also, by having four sides to the ring, the surfaces could be each magnetised with greater precision than possible with the rounded surface of the first ring. This ring was manipulated and tested in precisely the same way as the previous one. When magnetised around its edge, as shown in Fig. I, Diagram X., the results were as given in Fig. I′ in the same diagram, the figures representing the deflections noted when that part of the ring was in a direct line with the centre of the small suspended magnet. Figs. 2 and 2′ show the results after the magnet had also been applied to the top side of the ring, and Figs. 3 and 3′ after the magnet had been passed over its under side. Looking at the total of all the deflections of each test it will be seen that the increase of intensity is very small for the additional application of the magnet on either of its sides. These experiments were continued with a steel bar in the place of the ring, and it was found that if the bar were magnetised by drawing the magnet from end to end, as in Fig. 1, Diagram XI., then the maximum result is obtained by the first rub, unless a fresh surface of the bar passes under the magnet ; but if the magnet be passed from the middle of the bar to one end, and the magnet being then reversed, it be passed from the same point of the centre of the bar to the other end, as in Figs. 2 and 3, then the induced magnetism in the bar is increased by repeated applications of the magnet. In one experiment the following values were obtained :—

After one rub, deflection	137
,, five rubs, ,, ...	156
,, ten rubs, ,, ...	176
,, fifteen rubs, ,, ...	180

Although the magnetism induced into the bar is only increased by repeated application from 137 to 180, or 31 per cent. as measured by the energy of its polarised lines of force, yet its attractive power is nearly doubled, as the attraction between a magnet and its armature increases as the square of its "free magnetism." In drawing the magnet along the bar from end to end, as shown in Fig. 1, it was observed that the ends of the bar were not of the same intensity, the end B, where the magnet leaves the bar, being considerably stronger than the point A, where the contact was first made.

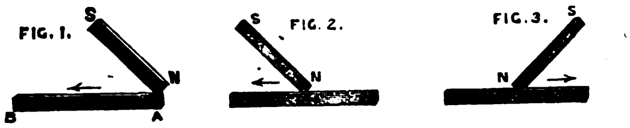

DIAGRAM XI.

It is just 100 years ago since it was first asserted that if an iron wire, not less than ten yards in length, were stretched in the open air, it would spontaneously give forth a sound when under the influence of a certain variation of the state of the atmosphere. On investigation, this was attributed to the effect of atmospheric electricity, and the correctness of that supposition was confirmed when it was demonstrated that the discharge from a Leyden jar through an iron wire produced the same phenomenon ; but no further notice appears to have been taken of the subject until 1837, when attention was called to the fact that if a flat spiral through which a current of electricity is passing, be brought near the pole of a powerful magnet, a sound would be heard. In the following year it was made known that if a soft iron armature be revolved rapidly before the poles of a horse-shoe magnet, a sound is produced, and in 1843 it was noticed that plates or rods of iron, when placed in the interior of a helix, gave a very decided sound each time the helix was connected with, or disconnected from, a strong electrical battery ; it being also, at the same time, asserted that a decided elongation of the iron rod occurred simultaneously with the sound. These phenomena were attributed to a change, produced by the magnetism, in the molecular constitution of the magnetised iron. The sound can be distinctly heard without external aid, but the

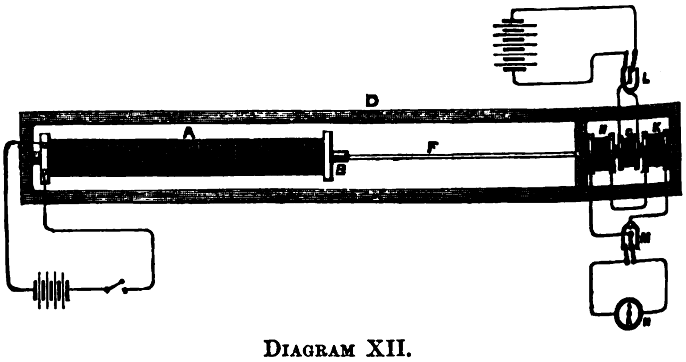

DIAGRAM XII.

supposed elongation of the rod requires very delicate appliances for measuring it, as under the most favourable conditions it is very minute. Prof. Joule, in one of his experiments, found that a bar of soft iron experienced a "decided elongation," which was about $\frac{1}{720000}$ of its total length, at the moment when the current by which it was magnetised was established, and a shortening at the moment when it was interrupted. These phenomena have frequently engaged the attention of experimenters, but no definite or satisfactory results have, as far as I am aware, been arrived at.

It has recently been experimentally demonstrated that a rod of iron only increases in length up to a certain point, and that if the strength of the exciting current passing through the helix be increased after the maximum length is reached contraction commences, and the bar apparently becomes shorter than its

Digitized by Google

original length. In my research in this direction, great difficulty was at first experienced from the want of a simple, but at the same time, efficient measuring apparatus; this was at last overcome by the construction and adoption of the apparatus as shown in Diagram XII; this arrangement proved most valuable, not only for these experiments for measuring the expansion and contraction of metals under the effects of varying temperatures, and other similar experiments; in fact, as a gauge it can be made as accurate and sensitive as "Newton's scale of colours."

A, is a helix of cotton covered wire (·083" diameter) wound in ten layers of 198 turns each, the resistance of the entire length being 1·613 ohm. Inserted in the helix is the iron bar B, 1·375 inches diameter and 27 inches in length; one end is rigidly fixed to the wooden frame D, and the other end carries a glass rod F, the further end of which passes freely through the hollow iron core of bobbin H and supports the centre bobbin of wire with hollow iron core, G. A fine screw adjustment permits this bobbin to have a movement of about half an inch along the glass rod, so that it can be placed in any desired position between the similar bobbins H and K, which are rigidly fixed to the wooden frame D. A rapidly alternating current can be sent through the wire on bobbin G by means of a reverser, L. The wire on bobbins H and K is so joined that the electromotive force induced therein from G exactly neutralises each when the bobbin G is placed midway between them, but under these conditions the slightest movement of G is sufficient to destroy this neutrality. In circuit with the wire on H and K is a reverser, M, which causes the induced current to pass in one direction through the mirror reflecting galvanometer N. The glass rod was of sufficient length to allow H to be 31in. from the iron rod B, and at that distance no direct inductive effect from B apparently affected H. Having established the point of no current by shifting G until its neutral position was found, which was exactly midway between coils H and K, then, by means of the fine screw, G was moved $\frac{1}{3000}$th part of an inch from its central position towards K. This slight movement was sufficient to produce a deflection of 44·1 divisions on the galvanometer scale. Having obtained this "constant," the values given in Table II. were obtained. It will be seen on referring to the table that the apparent elongation of the rod has reached its maximum when a current of four amperes is flowing in the helix, and, as the current increases, an apparent contraction of the bar takes place until, with a current of 16 amperes, the rod appears to be of the same length as at the commencement of the experiment, and as the current is further increased, the length appears to diminish, and with 21·5

amperes, it appears to be ·0000453 of an inch less than its original length. I have said *apparent* elongation and contraction of the rod, and I have intentionally done so, for it is my belief that neither elongation nor contraction takes place. I have already stated that if a helix of insulated copper wire be placed horizontally, and one end of a rod of soft iron be presented at one end of the helix, it will be attracted into the helix on the first impulse of the current, and place itself so that its centre coincides with that of the helix. And also that a helix of insulated wire, enclosing an iron core, not only causes the iron to become and continue a magnet by induction so long a current is flowing through the helix, but that the helix itself becomes a magnet, and possesses a sphere of magnetic lines of force quite independent of similar lines given out by the iron. This being so, it appears to me that, as soon as the current is passed into the helix, the lines of force from the rod endeavour to place themselves symmetrically with those given out by the helix, and thus, I think, is caused the slight movement of the whole rod, and not an elongation of it as supposed. When the rod becomes saturated, the intensity of its lines of force remain constant; but not so with those from the helix, as they continue to increase in intensity in proportion with the increase of the tension of the current passing through the circuit, and thus, I think, affect the lines of force of the rod, causing the latter to move in the opposite direction, which movement is mistaken for contraction. Just as I have shown the small magnet is moved by its lines of force adjusting themselves so as to be symmetrical with the lines proceeding from the iron rod or disc, so, I believe, is the iron rod moved by its lines of force adjusting themselves to those of the helix, and, I further believe, that the sound usually heard on making or breaking the current, in an experiment of this kind, is not due, as is supposed, to any effect in the iron itself, bat is caused by the lines of force adjusting themselves to each other; for, as is well known, the more intense the current the louder the sound, as instanced in the sounds given off by what is termed the "discharge" from powerful electrical machines, or that produced by an electrical phenomenon of nature which produces the sound called thunder.

Although far from having exhausted the subject—in fact, it appears to me inexhaustible—I feel that sufficient, if not more than sufficient, has been written to accomplish the purpose with which this pamphlet was commenced. I will therefore conclude by remarking that, what I have written being intended for instruction and not display, I have avoided all those phrases and technicalities which are so apt to puzzle and mislead, and have endeavoured to express my meaning in plain and simple words.

LEGAL.

The London and Provincial Winding Up.

In the Chancery Division of the High Court of Justice on Tuesday, before Mr. Justice Chitty, Mr. INCE, Q.C. (with whom was Mr. RIBTON), made an application on behalf of the solicitor to the liquidator of the London and Provincial Electric, &c., Company (Limited), under these circumstances:—In October the learned judge decided that the name of Mr. Geminari should be removed from the list of the contributories to this company. The same question now arose in regard to the names of three other gentlemen—Mr. Hall, Mr. Maitland, and Mr. Marposo. The understanding was that Mr. Geminari's should be a test case; but that was, as stated in the affidavits, "on the assumption that there are no facts relative to his case which are not applicable to the cases of the other parties." But there were distinguishing facts which made the cases not alike, and under these circumstances the liquidator desired the directon of the Court.

Mr. MAIDLOW, on the other side, contended that the question was asked whether the circumstances of the two cases were exactly the same, and to that no answer was given. The matter proceeded, and now, after the facts had gone against the company, the misrepresentations being found to be too flagrant to be passed over, they wanted to go behind the arrangement. The applicants in question had succeeded in the essence of the case between the parties. On the facts, the cases of the three gentlemen were even stronger than was that of Mr. Geminari.

The JUDGE said the point that there was a difference between the two cases was not raised until Geminari's case had been decided. The correspondence was not business-like; but he thought he should be going too far if he said that it was not open to the parties, even after that decision, to say that the facts of the cases were not the same. He had reluctantly come to this conclusion. Mr. Maidlow had come very near to establishing the fact that the agreement to make Geminari's a test case was concluded, but he had just fallen short of doing that. The case of the other three applicants would have to be heard.

COMPANIES' REPORTS.

Eastern Telegraph Company (Limited).

Report and accounts of the Directors for the half year ended 30th September last, to be presented to the twenty-seventh half-yearly ordinary general meeting, to be held at the Cannon-street Hotel, on the 21st inst., at one o'clock:—

The revenue for the period amounted to £331,419. 19s. 6d., from which are deducted £86,935. 11s. 10d. for the ordinary expenses, and £45,288. 17s. 3d. for expenditure relating to repairs and renewals and laying of cables, &c., during the half year. After providing £6,189. 13s. 4d. for income-tax, there remains a balance of £193,005. 17s. 1d., to which is added £1,101. 3s. 2d. brought from the preceding half-year, making a total available balance of £194,107. 0s. 3d. From this balance there has been paid—

	£	s.	d.
Interest on Debentures and Debenture Stock......	£27,260	10	6
Dividend on Preference Shares	20,296	17	4
Two Interim Dividends of 1¼ per cent. each on Ordinary Shares, with bonus of 1s. per share (¼ per cent.)	114,000	0	0
	£161,557	7	10

Digitized by Google

Leaving a balance of £32,649. 12s. 5d., which is carried forward to next account. The revenue includes £13,650 dividend for the half year upon the Company's shares in the Eastern and South African Telegraph Company, being at the rate of 7 per cent. per annum, and also £2,794. 10s. 9d. net receipts for the half year on the shares of the Black Sea Telegraph Company belonging to this Company. The several sections of the Company's cables and the land lines in connection therewith continue in good working order. The duplicate cable of the Eastern and South African Telegraph Company between Zanzibar and Mozambique, referred to in the last report, was successfully laid and opened for traffic in August last. All the cables belonging to that company are in good working order. The new twin screw steamship "Mirror," mentioned in the last report, was succesfully launched on the 21st December last by the builders, Messrs. R. Napier and Sons, Glasgow. The ship will be completed and ready for sea early in this year.

In August last an International Telegraph Conference was held in Berlin, to which the English companies were invited to send representatives. Important questions were discussed affecting the interests of the companies, and a proposal urged by the Indian Government to reduce the rate between England and India was agreed to. Important reductions in the European tariffs were also voted by the Conference. It is estimated that these alterations will affect the Company's revenue to the extent of £40,000 a year, but the Directors trust that with the growth of traffic resulting from reduced rates the loss will be gradually diminished.

Her Majesty's Government having invited tenders for establishing submarine telegraphic communication between St. Vincent (Cape de Verde) and the British possessions on the West Coast of Africa, this Company and the Brazilian Submarine Telegraph Company joined in sending proposals, which have been accepted, under which a subsidy of £19,000 a year for twenty years is granted by the Government in respect of a cable from St. Vincent to Bathurst, Sierra Leone, and other British possessions southward to the mouth of the Niger. A separate company, called the African Direct Telegraph Company, has been formed to carry out this project, and the Directors, with a view to the additional traffic which will be brought over this Company's lines, and the strengthening of its interests in Africa, have agreed, subject to the approval of the shareholders, to provide one-third of the capital required. As the larger part of such capital will be raised by debentures of the African Direct Company, it is estimated that this Company's proportion of the balance to be issued in shares will not exceed £75,000, which the Directors propose should be subscribed and paid for by the issue of a sufficient amount of this Company's Four per Cent. Debenture Stock, which is now at or above par. The arrangements with the Governments concerned are not yet completed, but further explanations on the subject will be given at the meeting.

In accordance with the provisions of the Articles of Association, two of the directors, Lord Sackville A. Cecil and Lord Alfred Paget, retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The auditors, Mr. Henry Dever, and Messrs. Quilter, Ball, and Co., retire, and offer themselves for re-election.

Direct United States Cable Company (Limited).

Report of the Directors for the six months ended 31st December last to be presented at the seventeenth ordinary general meeting of the Company, at the Cannon-street Hotel, on Friday, the 22nd inst., at 2 p.m.:—

For the half-year the revenue, after deducting out-payments, amounted to £38,115. 3s. 5d., against £68,824. 5s. 2d. (after similar deductions) for the corresponding half-year of 1884, being a difference of £30,709. 1s. 9d., against the half-year under review, owing to the operation of reduced tariff and competition. The working and other expenses for the same period, including income-tax, &c., but exclusive of cost of repairs of cables, amounted to £16,631. 13s., leaving a balance of £21,483. 10s. 5d. as the net profit of the half-year, making, with £10,733. 14s. 7d. brought forward from the previous half-year, a total balance of £32,217. 5s. For the corresponding half-year of 1884 the working expenses and other payments, exclusive of debenture interest, amounted to £16,857. 15s. Interim dividends of ¾ per cent. each, for the quarter ending 30th September, 1885, paid 24th October, 1885, and for the quarter ending 31st December, 1885, payable 23rd January, 1886, together amounting to £18,213, have been declared. The sum of £8,037. 3s. 9d. has been set aside to the reserve fund, thereby increasing that fund to £320,000, leaving a balance on the revenue account of £5,967. 1s. 3d., which has been carried forward. The interruption in the short section of cable mentioned in the last report was repaired on the 27th August. A break occurred in the main section on the 4th September last and was promptly repaired on the 7th of the same month. The cost of the above repairs, £3,362. 12s., has been charged against the reserve fund. With a view of affording additional facilities to the public joint offices have been established by the associated companies at Glasgow, Bristol and Havre.

Western and Brazilian Telegraph Company.

Report of the Directors, to be presented at the thirteenth ordinary general meeting of the Company at the Cannon-street Hotel, on January 21, at 12:30 p.m.:—

The total earnings amount to £127,396. 9s. 5d., an increase of £21,222 1s. 1d. compared with last year. The working expenses for the year, exclusive of renewals of cable, amount to £60,155. 19s. 4d., as against £61,871. 5s. 2d., a decrease of £1,715. 5s. 10d. The Company has had to replace by sheathed cable during the year 156 miles of the old unsuitable type of cable; the amount thus expended, £15,175. 10s. 6d., has been charged to the renewal fund. Including the amount brought forward from 1884, the balance to the credit of the revenue account is £42,296 17s. 9d., of which £10,000 has been placed to the renewal fund, leaving £32,296. 17s. 9d., from which the Directors recommend the payment of a dividend of 2¾ per cent. free of income tax, leaving £3,459. 0s. 3d. to be carried forward. This will give to the Preferred Ordinary shares 5 per cent. for the year and ½ per cent. on account of the year ending 30th September, 1884. The Directors would have been enabled to recommend the payment of a larger dividend to the shareholders, but for the loss on exchange, which has continued to increase, and amounted during the year to £10,648. 6s. 3d. In order to place the system between Pernambuco and Rio de Janeiro in perfect order, by the immediate removal of the remaining old strand type, which had become faulty, the Directors invited tenders for the manufacture of 200 miles of sheathed cable. The Company's ss. "Norseman" was ordered home to carry this cable to Brazil, and has now arrived out on the coast. During her absence the duty was provided for by placing the "Viking" in the centre of the system to be ready for any emergency. The Directors again draw attention to the extensive renewal of the old strand type of cable during the year; the steps now taken will complete the removal of this faulty type from the main revenue earning sections of the Company. Owing to pressing competition, efficient and speedy repairs have been absolutely necessary in order to keep the traffic over the Company's line. The remaining mileage of the strand type will now be reduced to 226 miles between Ceara and Pernambuco, and there is therefore a near prospect of reducing the heavy expenses caused by the maintenance of repairing ships, by rearrangements rendered practicable owing to the permanent improvement effected in the Company's system. It may be as well to remind the shareholders that, under many difficulties, no less than about 2,300 miles of solid sheathed cable have been substituted for the old unsuitable strand type. The retiring Directors are Mr. Andrews and Mr. Goodsall, who offer themselves for re-election. The auditor, Mr. Weise, retires, and is eligible for re-election.

NOTES.

THE TASMANIAN DUPLICATE CABLE.—The duplicate cable between Victoria and Tasmania has been completed.

THE ELECTRIC LIGHT OF ASIA.—The King's palace in Corea is now lighted with electricity of the Yankee brand.

OBITUARY.—Captain E. C. Armstrong, an electrician of Cincinnati, died 29th December, in that city, of consumption.

NOT ALWAYS REMEMBERED.—Faraday proved the magnetic condition of matter, and that magnetism, unlike electricity, cannot be insulated.

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 15th inst. amounted to £3,147.

THE EASTERN CRISIS.—A telegram from Philippopolis, dated 19th inst., announces that telegraphic communication with Constantinople has been re-opened.

UNDERGROUND WIRES IN PHILADELPHIA, U.S.A.—The City Councils of Philadelphia have decided to confer with the companies interested before beginning wire-cutting.

ELECTRIC LIGHTING AT HANLEY.—The Hanley Corporation have appointed a Committee to report on the desirability of lighting the town and public buildings with the electric light.

THE AMERICAN TELEGRAPHS.—It is stated that during the year the amount of press telegrams sent over the lines of the Western Union Telegraph Company alone was over a thousand million words.

THE TELEPHONE IN BOSTON, U.S.A.—Advices from Boston state that the net output of the Bell Telephone Company for the month ended December 20th was 1,597, against 379 in the month previous.

ON ACCUMULATORS.—M. Dieudonné has been invited by the Committee of the Neuilly Polytechnic Association to read a paper on electric accumulators and their practical application to existing industries.

THE SHEFFIELD TECHNICAL SCHOOL.—The new Technical School at Sheffield, which has just been established in connection with Firth College, will be formally opened on the 1st February by Sir Frederick Bramwell.

THE ELECTRIC LIGHT FOR WAR-SHIPS.—The Admiralty have ordered that in future all large ironclads belonging to Her Majesty's Navy are to be furnished with not less than four electric search lights and mirrors.

THE WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 15th January are £2,685, as compared with £2,624 in the corresponding period of 1885.

VOLCANIC ERUPTION.—Intelligence has been received at New York that an eruption of the volcano Colimba (? Colima) commenced on the morning of the 15th inst., when stones of an enormous size were ejected from the crater to a great height.

THE WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 15th inst. were £2,429, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

AN ANNUAL DINNER.—By permission of the Major-General commanding the Home District, the annual dinner (revived) of the non-commissioned officers 2nd Division Telegraph Battalion will take place at the Masons' Hall Tavern, Basinghall-street, E.C., on the 5th February, at 6:30 p.m.

THE CUBA SUBMARINE TELEGRAPH COMPANY. — The directors of this company have resolved, after providing for the dividend on the preference shares, to recommend the payment of a dividend on the ordinary shares at the rate of 7 per cent. per annum, free of income-tax, leaving £41 to be carried forward.

THE INDIAN EXHIBITION.—It is reported that the contracts for lighting next year's Indian and Colonial Exhibition at South Kensington have been arranged exclusively with the Anglo-American Brush Company, the Pilsen-Joel Company, and Messrs. Crompton. The lamps employed will be the Swan Company's incandescent lights.

THE NAVY.—The Admiralty have decided that the ships of our navy shall be exercised in night firing, and they have issued an order to the effect that once every half-year target practice shall be carried on at night. Vessels fitted with the electric light will make such use of it as the commanders think will best assist the accuracy of the firing.

SOCIETY OF ARTS.—Among the papers for which the dates are to be hereafter announced by this society, we notice "Domestic Electric Lighting," by W. H. Preece, F.R.S. On the 28th inst., Mr. Wm. Bottomley, jun., will read a paper on "Magnetism of Ships and the Mariner's Compass." The second course of the Cantor lectures will be upon "Friction," by Prof. H. S. Hele Shaw.

A NEW INSULATOR.—A new form of telegraph insulator has been patented by Mr. Benjamin N. Deblieux, of Bay St. Louis, Miss. It consists of two longitudinal sections placed together to form a joint in the middle and retaining the wire between them, the sections being clamped together, and so supporting the line wire without wrapping or cutting, and altogether obviating a tie wire.

SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS.—The first meeting of this society for the present session will take place on the 28th instant at the Institute of Civil Engineers, when the President, Prof. D. E. Hughes, F.R.S., will deliver an inaugural address, consisting of an account of his researches on "Self-induction of an Electric Current in relation to the Nature and Form of its Conductor."

LIGHT ON THE HIRE SYSTEM.—We have been favoured by the Anglo-American Brush Electric Light Corporation with a memorandum as to the hire of apparatus for electric lighting upon the purchase hire system. This Corporation, it appears, are now prepared to supply on hire dynamos, lamps, and all accessories for lighting, and to install the apparatus, the sums paid by way of rental being allowed for in the event of purchase.

COMMUNICATION WITH THE CONTINENT.—The *Daily Telegraph* understands that the Postmaster-General has consented to receive a deputation from Liverpool respecting a proposal to establish direct telegraphic communication between that city and the Continent. The necessity of this is stated to be the insufficiency of the present cables to transmit, with due speed, the messages despatched after the opening of the principal commercial and financial markets.

PERSONAL.—At the annual meeting of the Northern District Telephone Company, held in December, Mr. Clay, who has been well known in connection with the United Telephone Company for some years, was appointed manager of the

Digitized by Google

company, a position he has practically held for the past six months. The appointment of one so well known in the telephone world will, doubtless, be a subject of congratulation to the Directors and *employés* of the company.

Earthquake Shocks in Central America.—A telegram from Panama states that intelligence has reached there that the town of Amatitlan in Guatemala was nearly destroyed by an earthquake on the 18th December last. There were altogether 131 shocks, but no fatal results are reported. Shocks of earthquake have also occurred in other parts of Central America, and volcanic rumblings are reported from Ecuador, produced, it is supposed, by an eruption of Cotopaxi.

Synchronised Clocks.—The Estates Committee of the Birmingham Town Council proposes to establish a system of public clocks in the town. There are to be twenty clocks, erected in conspicuous places—at the intersection of streets by preference—and these clocks are to be controlled by electricity, so as to keep accurate time, and are to be illuminated at night. The estimated cost is £2,500 for the establishment of the clocks, and £200 a year for their maintenance.

The Electric Light on the Thames.—At the last fortnightly meeting of the Managers of the Metropolitan Asylums Board the report of the Hospital Ships Committee was brought up, in which they submitted an agreement to be entered into between the managers and the Commissioners of Sewers for Dartford for laying the cable for the electric light through the river bank at Long Reach, recommending that the common seal of the managers be affixed thereto, which was agreed to.

The Late M. Paul Baudry.—It is stated from Paris that the friends and admirers of the late M. Paul Baudry are arranging to get up an exhibition of his drawings, portraits, and minor paintings, but the work of works being the ceiling of the Opera House saloon, it is agreed that the room is to be thrown open to the public on Wednesdays and Thursdays from noon to midnight. As in the monumental apartment gas has been superseded by the electric light, this can be done at a small expense.

A Little Knowledge.—Our contemporary, *L'Electricien*, says that an amateur gravely asked, the other day, with what liquid the Gaulard-Gibbs secondary generators acted; and another gentleman, whose knowledge of electrical science was somewhat exceeded by his ambition, was desirous of achieving immortal fame by coupling up a dynamo with an electrostatic induction machine in order that due advantage might be taken of the large quantity of the current furnished by the one, and the enormous tension of the other.

A Humane Proposal.—Some degree of interest will be excited by the fact that Baron Leon de Lenval, of Nice, has offered a prize of 3,000f. for the best and most convenient adaptation of the microphone for the improvement of hearing in cases of partial deafness. The award committee will receive apparatus intended for competition up to the 31st of December, 1887, and the awarding of the prize will take place at the Fourth International Conference for Otology, which will be held at Brussels in September, 1888.

Taunton.—It is said that after a month's trial of the Thompson-Houston system of electric arc lighting at Taunton, the principal tradesmen met recently to consider the advisability of establishing a limited liability company to supply the light. Mr. Wharton explained the system; and Mr. Massingham, of Bath and Taunton (who was mainly instrumental in introducing the light into the town) said each arc lamp of 1,200 candle-power would, on an average, cost £15 a year. He estimated the capital required at about £5,000, which would, he said, erect machinery to supply 120 arc lights. A resolution in favour of adopting the light was carried unanimously.

A Submarine Volcano.—Information has been received at the Admiralty from the United States Government that the captain of the steam vessel "Janet Nicholl" reports the submarine volcano southward of Culebras Reef as having become active, and formed an island about two miles long in a north and south direction, and about 250ft. in height. A reef extends off the southern end of the island for a distance of a mile and half, and off the northern end for half a mile. Approximate position as given, lat. 20 28 S., long. 175 21 W. The position above given is thought to agree closely with that of the submarine volcano reported in 1877, about six miles northward of Honga-Tonga island.

Academie des Sciences.—At the general meeting, which was held at the 21st ult., the Bordin prize was awarded by the Academie to M. Edlund, Professor of Physics at the Royal Academy of Science, Sweden. The subject was that proposed for 1882, and revived for 1885, viz.:—"Researches upon the Origin of Atmospheric Electricity, and the Causes of the Excessive Development of Electric Phenomena in Storm Clouds." The subject proposed for 1884, which carries with it the mathematical prize, consisting of a medal of the value of 3,000f.—*i.e.*, "The Perfection in Each Important Point of the Application of Electricity to the Transmission of Work," is to be the subject for this year. The papers are to be forwarded to the secretary before the 1st of June next.

The Electric Light in Chicago.—M'Vicker's Theatre, Chicago, has adopted the arc light, to take the place of the calcium light, in lighting up scenery. The lamp used is a hand regulator with carbons 9·16in. in diameter. The chief peculiarity of the lamp, which is extremely simple, is a half cylinder of lime, which is hollowed out to enclose the arc. This lime acts as a reflector for the light, and itself becomes luminous, changing the quality of the light, so that the effect is nearly the same as that of the calcium light; in fact, without the use of the lime in this manner, the light could not be used for the purpose, as the lime steadies the light and decreases the danger of extinction. This theatre is lighted by the Edison system, which supplies the current for the arc light.

University of London.—A meeting of Convocation was held on Tuesday evening at the University Building, Burlington-gardens, Dr. Wood, chairman of Convocation, presiding. Mr. Carpenter, in the absence of Mr. R. H. Belcher, moved the reception of the report of the annual committee. This report gave as an appendix a long report, in much detail, presented by the sub-committee which had been appointed to consider the regulations of the matriculation examination. Briefly, the suggested amended syllabus omitted modern geography from the present subjects of examination, substituted mechanics for natural philosophy, and in place of chemistry gave one of the following branches of experimental science:—1. Chemistry. 2. Heat and light. 3. Magnetism and electricity.

The Electric Light in Mines.—Referring to the use of electricity for the lighting of mines, a writer in the *South Wales Daily News* calls attention to the fact that *The Times*, when commenting upon Sir F. Abel's inaugural address at the Society of Arts, in November last, dealing with this subject, maintained that "electricity is the one illuminating medium which can supply the light which miners want, without the flame which endangers them." The writer in the Welsh paper says "the fracture of a glass lamp, or the rupture of a con-

Digitized by Google

ducting wire in a mine might be as much fraught with danger as the injury of a safety lamp or the lighting of a pipe." We are glad that this gentleman said *might*. There is an old story in which the usefulness of this word is set forth, together with the merits of the qualifying *if*! No doubt our readers will remember it.

EARTHQUAKE IN CORNWALL.—Another earthquake occurred in the West of England on Wednesday morning. At Bodmin the houses were so much shaken as to startle the inhabitants. At Mevagissey a long rumbling noise was heard. In some of the houses the creaking of beams and flooring resembled the straining of a ship in a rough sea. At St. Blazey the inhabitants were so shaken in bed that they arose in fright. Buildings swayed to and fro and tottered. The shock took place at half-past six, and lasted about six seconds. Persons at St. Austell were terrified by a deep, rumbling sound, which was described as terminating in a noise like that of an explosion in the distance. Houses were shaken, and china and glass were set jingling. Some persons describe the sound as being like that of two distinct explosions rapidly following each other, the latter being by far the louder. At Wheal Eliza Mine the shock was so great that the miners ceased work for a time, fearing that water had broken in.

OVERHEAD WIRES.—The following letter has been received by a gentleman who pointed out to the Postmaster-General that serious loss is incurred by the commercial community through the breakdown of telegraph wires by snowstorms, &c., and inquired whether the department contemplated an established system of underground wires, similar to those now in use in the German Empire:—"General Post Office, London, January 15. Sir: I am directed by the Postmaster-General to acknowledge the receipt of your letter of the 12th inst., and to inform you in reply that this department has already placed a very large number of wires underground in and around London and in and around the principal towns in the United Kingdom. More works of this kind will be carried out from time to time as opportunity offers, but the Postmaster-General cannot hold out a hope that the telegraph wires throughout the country will be placed underground.—Yours, &c., C. H. Patey."

TELEPHONY IN THE NORTH.—The Northern District Telephone Company are opening the new year in a very satisfactory manner, as regards work, and during 1886 it is intended to complete most of the trunk lines, several of which are in hand already. The line between Wingate Colliery and Hartlepool—a distance of 12 miles—was opened just before Christmas, and has proved a great success, which is highly satisfactory, as it constitutes a very important part of the trunk line between Sunderland and Hartlepool. Subscribers to the company's system in Sunderland have been enjoying a little theatre diversion made easy, as the Theatre Royal in Newcastle has been connected up. An ingenious subscriber has fixed up one of the large advertisement placards of the pantomime depicting all the scenes and characters, and says that with the aid of that and the telephone it is just as good as being in the theatre. It is satisfactory to hear that the company have not at all suffered from the trouble of broken wires during the winter.

THE INSTALLATION AT THE PALAIS ROYAL.—During the last two months Mr. Jehl, of the Paris Branch of the Edison Company, has been occupied with the installation at the Palais Royal. This is divided into three parts, *i.e.*, Le Palais Ancien Côté du Roi, 263 lamps; Le Palais Ancien Côté de la Reine, 203 lamps; Le Nouveau Palais, 883 lamps; or a total of 1,349 lamps in all. The Old Palace is being completely installed, but at the New Palace it is only intended to put in new sockets, lamps, switches, &c., and to alter the wiring done by the Brush Company so as to allow of single lamps being used in parallel circuit. About 180 lamps have already been fitted up in the Queen's private apartments in the Old Palace, and these are lighted every night, the current being conveyed through an overhead cable from the dynamos at the theatre, a distance of about 380 metres. An underground cable will, however, be laid as soon as the weather permits. In the dining and smoking rooms of the New Palace the full complement of 182 lamps has been put in. M. Jehl expects to complete his task in about two months' time.

ELECTRICAL CONDUCTIVITY OF AIR UNDER REDUCED PRESSURE.—Experiments, by T. Homén, on the relation of the conductivity of air to the pressure, have led to the opposed conclusions that an absolute vacuum is a perfect non-conductor, and a good conductor of electricity. In this paper, an elaborate series of experiments on the conductivity of air in discharge tubes under various degrees of pressure are described. The results show that the phenomena of conductivity of air under reduced pressure are of two kinds, the one, the particular resistance of the air, which is proportional to the distance between the electrodes, the other the actual resistance of the electrodes themselves. The former is independent of the diameter of the air column, and its increase is nearly proportional to the pressure, whilst the latter increases very quickly with decrease of pressure, and under low pressures reaches a point at which the resistance is such that electricity, even at the highest difference of potential, cannot overcome it. These results are not in accordance with the view that a vacuum is a good conductor of electricity.—*Ann. Phys. Chem.*

THE AMERICAN EXHIBITION.—The American Exhibition is to open with a big, big boom on the 2nd of May, 1887. Arrangements are being made to include a Press Pavilion, an Atlantic Cable Office, an Electrical Elevated Railway, and reproductions of the façades and interiors of remarkable hotels and public buildings. The lighting of the buildings and the illumination of the grounds, avenue, gardens, and fountains by electricity, are already having the most careful attention of the Council, and will in themselves constitute an especially interesting and attractive display. The Executive Council invite tenders from persons and firms desirous of making proposals for concessions, or permits to sell, at the forthcoming exhibition. Forms of tender may be obtained on application to the Secretary, 7, Poultry, London, E.C.; 32, Nassau-street, New York, and to the State Commissioners. Among other things these concessions are for an electric railway, lectures, and telephones. There will be seven entrances to the buildings and gardens, all of which will be brilliantly illuminated at night by the electric light.

BY HYDRAULIC POWER.—A pamphlet by Mr. A. T. Walker, M. Inst. C.E., on behalf of the promoters of a Bill for the formation of a Hydraulic Power Company for Leeds, has been issued. This power is said to be in effective operation both at home and abroad, and not only in connection with railway and dock works and other large undertakings, but in smaller quantities for the driving of machinery of limited power. It is contemplated that not more than 300 indicated horse-power shall at first be provided, with accumulators giving, when fully charged, an additional 400 indicated horse power. Is is intended among other things to supply people who have not sufficient work for a boiler of medium size; others whose work would be more economically done by hydraulic than by steam direct; to supply small consumers, enabling them to do by

Digitized by Google

power work they now do by hand, thus cheapening production; to render offices at the top of high buildings quite as convenient and as valuable as those on the ground floor, by being able to take up passengers and goods safely and rapidly; and lastly, providing power to warehouses, offices, and banks, for driving dynamos wherewith to light by electricity.

AN INTERESTING INSTALLATION.—Park Hill, Streatham, the residence of H. Tate, Esq., has been lighted throughout with glow lamps by Goolden and Trotter. The installation consists of about 200 lights, the current being supplied by a Goolden-Trotter dynamo and accumulators, the motive power being an eight horse-power gas engine. The lamps are Woodhouse and Rawson 50-volts of various candle-power, and the installation has been for several months entirely in the charge of the butler, Mr. J. Codling, who states that it gives entire satisfaction, and with the exception of some leakage of acid from the accumulators, no trouble at all. The installation is peculiar and interesting as being the first example of the employment of the magnetic switch introduced by this firm, whereby the lamps are lighted and extinguished from both inside and outside the rooms, or from several points in the same room, so that it is never necessary to enter a dark room; a great saving in the leads is also effected, as they are not required to be brought down to the switch buttons, which bring the switch into action by means of a few Leclanché cells on an ordinary electric bell circuit, being in some instances fully 100ft. away from the switch.

SMALL INSTALLATIONS.—On December 24 Sir Archibald Campbell, Bart., M.P., of Blythswood, gave an entertainment in which a Christmas tree was lighted with 120 glow lamps of 20 candle-power. The current was supplied from a Goolden-Trotter dynamo and accumulators, and the tree was in every sense of the word a brilliant success. The lamps were Woodhouse and Rawson 42 volts. — At the bazaar in connection with the church and schools of Southowram, near Halifax, a large Christmas tree was lighted for three evenings with such good effect that no other lights were needed in the room in which the bazaar was held. The dynamo weighed only 1¼cwt., and the whole apparatus was sent over in a cab and set running the same afternoon off the one-half horse-power gas engine which is used for blowing the organ of Southowram Church. It appears that the clergy in the neighbourhood of Halifax take more interest in electric lighting than the manufacturers and millowners. Messrs. Goolden and Trotter lit the Church of St. John's in the Wilderness, Mytholmroyd, with three arcs inside and one on the tower, with a dynamo nearly half a mile off, for the harvest festival a few months ago, showing up the decorations with excellent effect.

MORE LITIGATION.—The United Telephone Company has served two writs upon Mr. W. H. Fleming, of Liverpool, for using the telephones of the New Telephone Company, comprising the "valve" transmitter and the "English mechanic" receiver. The former of these instruments, though it possesses no diaphragm, is alleged to infringe Edison's claim to the combination of a diaphragm or tympan with electric tension regulators; and the latter instrument, though its armature is borne upon a membrane, such as gold-beaters' skin, is alleged to infringe the Bell patent, in which such instruments are expressly disclaimed. Whether the monopoly company seriously thinks that it can prove the infringements of which it complains, may be doubted, as the New Company is known to be a very powerful association, with fighting capacities, and with ample funds for defending its rights. The entire body of electricians are interested in the issues involved; for, since the extraordinary failure of justice in the Bassano case (in which Mr. Justice North has never yet delivered his judgment, though the verdict was rendered many months ago), this is the first real attempt to decide whether a "disclaimer," such as that in the Bell patent, can be held to give the public any real protection.

DOMESTIC LIGHTING.—An extensive installation of domestic electric lighting has just been completed at Oakworth, Yorkshire, the seat of Mr. Isaac Holden, M.P. It comprises about 150 incandescent lamps; and a dynamo capable of supplying 100 incandescent lights of 20 candle-power each. There is a secondary battery of 110 cells in two sets of 55 in a little house in the garden, which is capable of maintaining 100 lamps for ten hours without recharging. The power for driving the dynamo is supplied by an 8 horse-power Crossley gas engine. The dynamo chamber and engine house is connected with Oakworth House by a large cable, which is laid to the butler's pantry, from which radiate all the minor cables for the various rooms. In the large reception rooms the splendid chandeliers formerly used for gas have been retained and adapted for carrying incandescent lamps, which are arranged in groups, screened by engraved and ground glass globes. In each room and hall there are also independent switches. The installation has been carried out by Messrs. Muir and Mavor, of Glasgow, who are contractors to the Government for the lighting of the Glasgow General Post Office, in which installation there are 400 incandescent lamps and 10 arc lights, most of which are running day and night.

AT THE SALPETRIERE.—At the Salpetriere Hospital, in Paris, electricity is one of the most important elements in the treatment of the sick. Its creation, in 1877, was due to the initiative of Prof. Charcot, and its organisation was the work of Dr. R. Vigoroux, who has continued to direct it ever since its foundation. The patients pass into the room for treatment, where most of them take a seat upon two rows of insulating stools, where they receive electricity from two machines in the middle of the room. They are thus in the first place submitted, for a length of time varying with the case, to an electric bath. Then the operator, provided with exciters, makes such an application to each person as the case requires. Those who are not to sit upon the stools go over to an electro-therapeutic table, where they receive electric applications of a different kind. The total number of persons treated at each sitting may be estimated at 200. The results of this electric treatment are said to be of the most satisfactory character. The electric machines are of the Carre system, but arranged horizontally. Dr. Vigouroux is now having others constructed on a new plan. The manner in which they are set in motion is as follows:—A Gramme motor located in the room actuates a shaft, on which there are distinct pulleys that receive two belts for the electric machines and one for a laboratory Gramme machine. The current is furnished by a dynamo situated about 600 yards off, alongside of the large steam engine of the laundry. This transmission of power was put in by Messrs. Breguet.

ELECTRIC LIGHT FOR STEAMSHIPS.—Not long ago several of the heads of departments of Messrs. Wilson, Sons, and Co. paid a visit to the steamer "Torpedo," in the Alexandra Dock, to witness the completion of many of the improvements which have been effected on this small but very beautiful addition to the Wilson line. Perhaps the most interesting feature on board this steamer is the electric lighting, which has been introduced all over the ship. The new system of lighting has been fitted on board by Mr. Muse, who has been most successful

Digitized by Google

not only in producing a most perfect light, but in his distribution of the electric lamps. The engine room, where the final touches were being completed, was as light as day, whilst the saloon was rendered most brilliant. For working purposes, however, the side and masthead lights were the points of greatest interest to those connected with the ship, and here it would appear the greatest success had been attained. The masthead light had all the brilliance of a lighthouse on a small scale, and will be visible for a great distance, and the side lights were equally effective. The starboard or green light is always the weakest light on board a ship, and the most difficult to see from a distance, especially if the weather is not clear, but the "Torpedo's" green light showed out most perfectly, although during a great portion of the time it was exhibited rain was falling heavily. The "Torpedo" has been several voyages to and from Liverpool and Jersey, at which latter place she has been the object of very great interest. Messrs. Paterson and Cooper's machine is used on board, and gives great satisfaction.

LIGHTSHIPS AND TELEGRAPH STATIONS.—A very interesting and successful experiment was tried recently in Walney Channel with a model of Captain Moody's floating lightship and telegraph stations. The model was supposed to represent a floating lightship and telegraph station, with a hull 80ft. by 80ft., with a light 60ft. above the water line. The vessel is constructed with four equal rays or projections proceeding from a central circular deck protected by an iron bulwark from three to four feet high, and has many novel and useful features. She is moored by four strong cables running from the curvatures between the rays, and if the vessel is to be moored in mid ocean these cables will be attached to cylinders or buoys sunk to a certain depth, and from these again will be strong cables with anchors. If the vessel is placed in position anywhere near land four cables with as many anchors are required. The telegraph cable runs through a well in the centre of the vessel, and cannot by any possibility become twisted with the cable chains. The light is placed in an ordinary lighthouse lantern at the top of a lattice-work tower made of steel with ladders running up the inside. This tower is made pretty much in the same way as the three largest which carry the electric light on the Ramsden Dock, only it is much more substantial. On the occasion of the experiment the "station" was towed out into the channel and moored in very rough water. Great satisfaction was expressed with the trials. The model will next be sent to the Trinity Board, after which it will be sent to the Shipperies Exhibition, which is to be held at Liverpool.

THE PROPOSED NEW CABLE.—Some little time ago, says the *Colonies and India*, we mentioned that Her Majesty's Government had invited tenders for the laying, maintaining, and working a telegraph cable between Halifax (Nova Scotia), Bermuda, and Jamaica. The amount to be paid by way of subsidy was not stated, but some enterprising gentlemen in the City of London have had the matter under consideration, and the result is there has just been registered here "The International Cable Company (Limited)," with a capital of £1,000,000 in 100,000 shares of £10 each, the object of which is, as stated in the prospectus, to "establish, maintain, and work lines of telegraphic communication between the Azores, the West Indies, Canada and the United States, from such points on the coast of Great Britain and Ireland and the continent of Europe, or elsewhere, as the company may determine; also between any points on the coast of Canada, the West Indies, the Azores, the Bermudas, Central America and the South Pacific coast, and from the coast of Canada or America to Japan and the continent of Asia; to connect cables of the company with the Government internal telegraphic system of the Dominion of Canada, and procure from the Governor of Canada by letters patent under the Great Seal of Canada, or otherwise, a charter of incorporation upon such terms as may be expedient." The first subscribers, who take one share each, are Mr. George Gordon Leycester Macpherson, merchant; Mr. W. Pope, Mr. Ernest Heathfield, merchant; Mr. James Jacker, Mr. Thomas H. Craven, solicitor; Mr. Walter Galt Gibbon, accountant; and Mr. George Barrow Holroyd. The number of directors is to be not less than seven nor more than fifteen, and for their services the sum of £5,500 a year is to be divided amongst them. It will be remembered that in calling for tenders the Postmaster-General distinctly stated that Her Majesty's Government would have no liability or responsibility in respect of the cable beyond the payment of the subsidy, which may be for a term of twenty years, and will be payable at the end of each complete period of twelve months, provided that the cable has been maintained in good working order, and that a continuous service between the United Kingdom and Bermuda and the British possessions has been maintained. The communication must be established and in efficient working order within twelve months of the acceptance of the tender.

THE ELECTRICAL CONDITIONS OF THE HUMAN BODY.—The following is the syllabus of the Lumleian Lectures for 1886, by William H. Stone, M.A., F.R.C.P.:—Importance of placing the physiological and medical application of electricity on a physical basis of absolute measurement. Previous work done in this direction by Dubois Reymond, Count Du Moncel, and others, somewhat scanty. The human body exhibits: (I.) electrical resistance; (II.) electro-chemical capacity; and (III.) electrolysis. I. Resistance has been enormously over estimated owing to the high insulating power of the skin. This variable factor can be reduced to zero by obtaining perfect contact. Measurement of resistance by (*a*.) momentary contacts; (*b*) alternating currents; (*c*) Mance's second method. Errors involved in method *a*, by electrolysis, which sets up counter E.M.F. and in *b*, by electro-chemical or voltametric capacity. Resemblance of the human body to a faulty submarine cable. Mance's method *c*, intended originally for the latter, entirely removes these difficulties, and enables the three processes to be independently determined. II. Alternating induction currents as used in physiology have not been hitherto measured. The two momentary currents of Rumhkorf's coil of very unequal intensity. Helmholtz's correction. Superiority of a tuning fork commutator and battery in this respect. Methods of measuring alternating currents by (1) the dynamometer; (2) the quadrant electromometer. Estimation of the electrostatic capacity of the body by methods used in calibrating condensers. III. The amount of electrolysis produced by a constant current far larger than hitherto supposed. Accident to the Countess Du Moncel. Electric lighting accidents. Question whether the body behaves as a solid or a liquid conductor. Evidence that its resistance diminishes instead of increasing with heat. Great diminution of resistance on the occurrence of dropsical effusion. Physiological deductions from the above observations; traces of a mechanical law governing the length of the bones as levers, and the bulk of the muscles as powers. Great lessening of resistance in atrophied muscle, and in certain metallic impregnations. Predominant nervous action of rapid alterations of potential. Speculation as to the possibility of the human nervous system distantly resembling a duplexed telegraph cable, in which a transmitted impulse is balanced and inhibited at the sending station, but unbalanced and exhibited at the receiving station.

ELECTROMAGNETIC INDUCTION AND ITS PROPAGATION.

BY OLIVER HEAVISIDE.

(Continued from page 188.)

The Mechanical Action between two Regions.

Summary of some results of Vector Analysis.—In order to keep the present section within limits, it will be desirable to first give a short summary of certain general relations, discussed at length in previous articles in this journal.

Let there be a distribution throughout space of a vector H, to be mentally realised by drawing lines following its direction, packing them closely where H is strong, loosely where it is weak. H may be the intensity of electric or magnetic force, the mechanical force on the unit of the corresponding matter. The field of H is decomposable into two fields of very different natures, say, $H = F + K$, such that F is a polar force, its line integral round any circuit being zero, and K has no divergence, or its lines are entirely closed. From this property it follows that ΣFK through all space is zero, making

$$\Sigma H^2 = \Sigma F^2 + \Sigma K^2.$$

The divergence of H is that of F only; the curl of H is that of K only. Let

$$\text{div.}H = 4\pi\rho, \qquad \text{curl.}H = 4\pi\Gamma; \quad . \quad . \quad . \quad . \quad (12a)$$

then ρ is the density of the "matter" of F, and Γ is the density of the "current" of K. (Say magnetic matter and electric current, or electric matter and negative magnetic current; but, so far as the present section is concerned, the matter and current are simply defined by (12*a*).) Let P and A be the potentials at any point, Q, of the matter and the current, according to

$$P = \Sigma\rho/r, \qquad A = \Sigma\Gamma/r, \quad . \quad . \quad . \quad . \quad . \quad (13a)$$

r being the distance from ρ or Γ to the point Q where P or A is reckoned. Then

$$F = -\nabla P, \qquad K = \text{curl.}A, \quad . \quad . \quad (14a)$$

show the derivation of F and K from the corresponding potentials. Also

$$F = -\Sigma\rho f, \qquad K = -\Sigma V\Gamma f, \quad . \quad . \quad (15a)$$

if f be the vector force at the place of ρ or Γ due to unit matter at Q, where F or K is reckoned. If we call the quantity $\Sigma H^2/8\pi$ the energy of H, the total energies of F and K are

$$\tfrac{1}{2}\Sigma F^2/4\pi = \tfrac{1}{2}\Sigma P\rho, \qquad \tfrac{1}{2}\Sigma K^2/4\pi = \tfrac{1}{2}\Sigma A\Gamma. \quad . \quad (16a)$$

The mechanical force per unit volume is

$$\rho H + V\Gamma H \quad . \quad . \quad . \quad . \quad . \quad . \quad (17a)$$

Limitation to a bounded region.—The above referring to all space, in order to apply the results to a bounded region we must suppose $H = 0$ outside it, for our temporary purpose, but without altering H within the region. This makes ρ and Γ zero in the outer region, keeps them unaltered in the inner region, and, owing to the sudden cessation of H at the boundary, introduces new matter and current there. Let σ_1 and γ_1 be the surface representatives of ρ and Γ. They are given by

$$N_1 H = 4\pi\sigma_1, \qquad VN_1H = 4\pi\gamma_1, \quad . \quad . \quad (18a)$$

corresponding to (12*a*), N_1 being the unit normal from the boundary to the inner region. If, now, we include this surface matter and current in the former ρ and Γ, the results are applicable to the inner region outside which H has been abolished, or to all space if we like to keep the outer H zero. P must be the potential of ρ and σ_1, and A the potential of Γ and γ_1.

As H in the inner region is the same as before H in the outer region was abolished, it follows that the force in the inner region due to the surface matter and current is identically the same as that due to the abolished ρ and Γ in the outer region. And, as there is now no force in the outer region, it follows that the force in the outer region due to the surface matter and current is the negative of that due to the matter and current in the inner region. If, for example, there was originally no ρ and no Γ in the outer region, the force in the inner region due to the surface matter is the negative of that due to the surface current, so that together they produce no force in the inner region, whilst in the outer region their joint effect is the negative of that of the ρ and Γ in the inner region.

Similarly we may treat the outer region as self-contained, by making $H = 0$ in the inner region, and introducing surface matter and current given by

$$N_2 H = 4\pi\sigma_2, \qquad VN_2H = 4\pi\gamma_2,$$

N_2 being the unit normal from the boundary to the outer region. Since $N_2 = -N_1$, σ_2 and γ_2 are the negatives of the former σ_1 and γ_1. The force in the inner region due to σ_2 and γ_2 is the negative of that due to the ρ and Γ in the outer region, whilst in the outer region it is the same as that due to the abolished ρ and Γ in the inner region. It will be convenient to have a fixed way of reckoning the normal and the surface matter and current. Let the normal be always + from the boundary to the outer region, and be called N, the same as the former N_2. Similarly call the surface matter and current σ and γ, corresponding to N, being the former σ_2 and γ_2, so that $\sigma_1 = -\sigma$, and $\gamma_1 = -\gamma$.

Internal and External Energies.—Let ρ_1, Γ_1 and ρ_2, Γ_2 be the matter and current densities in the inner and the outer regions, σ and γ the surface matter and current (as just defined), P_1, A_1, P_2, A_2, and P_0, A_0, the potentials of the inner, the outer, and the boundary matter and current, after (13*a*). Then the energies in the internal and the external regions are

$$\tfrac{1}{2}\Sigma(A_1 - A_0)(\Gamma_1 - \gamma) + \tfrac{1}{2}\Sigma(P_1 - P_0)(\rho_1 - \sigma),$$
and
$$\tfrac{1}{2}\Sigma(A_2 + A_0)(\Gamma_2 + \gamma) + \tfrac{1}{2}\Sigma(P_2 + P_0)(\rho_2 + \sigma), \quad . \quad . \quad (19a)$$

respectively, by (16*a*). But also, by disregarding the boundary altogether, the total energy in both regions is

$$\tfrac{1}{2}\Sigma(A_1 + A_2)(\Gamma_1 + \Gamma_2) + \tfrac{1}{2}\Sigma(P_1 + P_2)(\rho_1 + \rho_2) \quad . \quad . \quad (20a)$$

So the sum of the two expressions in (19*a*) equated to that in (20*a*) gives us the necessary relation

$$\Sigma(A_1\Gamma_2 + P_1\rho_2) = \Sigma\{\gamma(A_2 - A_1) + \sigma(P_2 - P_1) + A_0\gamma + P_0\sigma\};$$

both members being expressions for the mutual energy of the matter and current in the two regions. If there is no ρ or Γ in the outer region, this is equivalent to

$$0 = \Sigma(A\gamma + \Gamma\sigma - A_0\gamma - P_0\sigma),$$

and the external and the internal energies are

$$\tfrac{1}{2}\Sigma(A_0\gamma + P_0\sigma), \qquad \text{and} \qquad \tfrac{1}{2}\Sigma(A\Gamma + P\rho) - \tfrac{1}{2}\Sigma(A_0\gamma + P_0\sigma),$$

respectively. The first of these we may also write as $\frac{1}{2}\Sigma P\sigma$, if $H = -\nabla P$, as it can be expressed, or else as $\frac{1}{2}\Sigma A\gamma$, if curl.A $= H$, which is possible when $\Sigma\sigma = 0$.

Mechanical Force between the Regions.—There being matter and current in either or both regions, the resultant force on the inner region is

$$\Sigma(\rho_1 H + V\Gamma_1 H), \quad . \quad . \quad . \quad . \quad . \quad (21a)$$

the summation extending throughout the region. It is zero on any region in which there is no matter or current. Similarly

$$\Sigma(\rho_2 H + V\Gamma_2 H) \quad . \quad . \quad . \quad . \quad . \quad (22a)$$

is the resultant force on the outer region, the summation extending through *it*. Since the summations in (21*a*) and (22*a*) together include all space, the one sum is the negative of the other. Or, as (21*a*) is the resultant force *of* the outer *on* the inner region, and (22*a*) is that *of* the inner *on* the outer region, the one is the negative of the other. That is to say, action and reaction are equal and opposite; or, stress is mutual; or, a complete dynamical system cannot set itself moving, when taken as a whole. Both (21*a*) and (22*a*) are expressed by

$$\pm\tfrac{1}{2}\Sigma(\sigma H + V\gamma H), \quad . \quad . \quad . \quad . \quad (23a)$$

taken over the boundary, using the + sign to express the force of the outer on the inner region, and the − sign to express that of the inner region on the outer. Comparing (23*a*) with (22*a*) and (21*a*), we see that boundary matter and current takes the place of the matter and current in the inner or the outer region as the case may be. We may verify the equivalence of (23*a*) to the others by differentiation, applying the perennially useful and labour-saving Theorem of Convergence to either

Digitized by Google

region with the common boundary; but the reason of (23a) and its necessity may be more simply seen thus. When we abolish the external field, and put $-\sigma$ and $-\gamma$ on the boundary, we make the inner region, with the boundary matter and current, a complete system, on which there is no resultant force. The resultant force on the surface matter and current $-\sigma$ and $-\gamma$ is therefore the negative of that on the internal ρ and Γ. But the surface matter and current are, so far as the mechanical force between the regions is concerned, equivalent to the external matter and current. Hence the resultant force on σ and γ is the same as that of the ρ and Γ in the outer region on the ρ and Γ in the inner. Hence, in (21a) we may put σ and γ for ρ_1 and Γ_1. But then, since by this we turn the volume integral into a surface integral, we must take the mean value of H through the infinitely thin layer of the surface matter and current. This is $\frac{1}{2}$H, since $H=0$ outside when the surface matter and current are taken instead of the external ρ_2 and Γ_2. Hence the presence of the $\frac{1}{2}$ in (23a.)

The vector in that expression, viz.,

$$\tfrac{1}{2}(\sigma H + V\gamma H), \quad . \quad . \quad . \quad . \quad . \quad (24a)$$

is the vector stress, according to the last section, regarding one side of it only, the force of the outer on the inner region per unit area of the boundary. Putting $\sigma = NH/4\pi$, $\gamma = VNH/4\pi$, it takes the form

$$H.(HN/4\pi) - N.(H^2/8\pi) \quad . \quad . \quad . \quad . \quad (25a).$$

Hence it is a simple Maxwellian stress of intensity $H^2/8\pi$.

It is not necessary, in reckoning the resultant mutual force between the regions, to take H in the formulæ, *i.e.*, to take the intensity of the force due to the matter and current in both regions. Thus, H_1 being the force intensity due to ρ_1 and Γ_1, and H_2 that due to ρ_2 and Γ_2, the resultant forces on the inner and outer regions are

$$\Sigma(\rho_1 H_2 + V\Gamma_1 H_2) \qquad \text{and} \qquad \Sigma(\rho_2 H_1 + V\Gamma_2 H_1)\,. \quad (26a)$$

respectively. Comparing with (21a) and (22a) we see that this is equivalent to saying that

$$0 = \Sigma(\rho_1 H_1 + V\Gamma_1 H_1), \qquad 0 = \Sigma(\rho_2 H_2 + V\Gamma_2 H_2)\,. \quad (27a)$$

Remember that in the inner region H_2 is the same as the force intensity due to $-\sigma$ and $-\gamma$; whilst in the outer region H_1 is the same as that due to $+\sigma$ and $+\gamma$. The (26a) expressions are equivalent to the boundary summations

$$\Sigma(\sigma H_2 + V\gamma H_2) \qquad \text{and} \qquad -\Sigma(\sigma H_1 + V\gamma H_1)\,;$$

or, in terms of the surface H_1 and H_2 only, to

$$\pm\,\Sigma\{H_1(NH_2) + H_2(NH_1) - N(H_1H_2)\}/4\pi. \quad . \quad (28a)$$

H and P in either region due to ρ and Γ in the other.—For distinctness, let there be no ρ or Γ in the outer region. H is then given by

$$H = -\Sigma(\rho f + V\Gamma f) = -\nabla\Sigma p\rho + \text{curl}.\Sigma p\Gamma \quad . \quad . \quad (29a)$$

H being reckoned at a fixed point Q, and p and f being the potential and force intensity at the place of ρ and Γ due to unit matter at Q. That is,

$$p = 1/r, \qquad f = r_1/r^2$$

if r be the distance from Q to the place of ρ or Γ, and r_1 a unit vector along r from Q. For ρ and Γ we may substitute the surface matter and current, when the point Q is in the outer region, thus

$$H = -\Sigma(\sigma f + V\gamma f) = -\nabla\Sigma p\sigma + \text{curl}.\Sigma p\gamma \quad . \quad . \quad (30a)$$

Thus, since σ and γ depend only upon the boundary H, if H be given only over a closed surface, we know H through the whole external space, so far as it depends upon ρ and Γ within the surface, and therefore definitely throughout the external space when there is ρ and Γ only within the surface (or, in the extreme, upon it). As we change the form of the boundary, the distributions of the surface σ and γ change. There may be matter only, viz., when H is normal everywhere, or the boundary is an equipotential surface (say due to an electrically charged conductor). There would be current only if H could be everywhere tangential, but this is not possible if H be magnetic force, at least without having current in the outer region. In general, we have both matter and current. Although the external field is definitely fixed by the surface H, we can get no information from it as to the internal field, except that $\Sigma\sigma = \Sigma\rho$, or the matter on the surface is the same in amount as that within it. If this be not zero, there is matter of amount $-\Sigma\sigma$ or $-\Sigma\rho$ on the surface at infinity, if we stop the extension of space. A closed current is equivalent to equal amounts of + and − matter; so is a magnet.

In the second form of (30a), the force H is derived from the scalar potential of σ and the vector potential of γ. We can, however, derive it from a scalar potential only, thus. Since the surface H, say H_0, is given, the surface potential can be found, except as regards a constant, by a line integration on the surface from a fixed point, whose potential is taken as zero. Thus, P_0 being the surface potential,

$$P_0 = -\int H_0 ds\,; \quad . \quad . \quad . \quad . \quad . \quad (31a)$$

$H_0 ds$ being the scalar product of H_0 and ds the vector element of the line of integration. Then, if P is the potential at the external point Q, we shall have

$$P = \Sigma p\sigma - \Sigma(fN)P_0/4\pi, \quad . \quad . \quad . \quad (32a)$$

and $H = -\nabla P$. The first Σ gives that part of the external potential due to the surface matter, $\sigma = H_0N/4\pi$. The second part is the scalar potential of the current; that is, if it be electric current, it is its magnetic potential. Or, it is the external magnetic potential of a closed magnetic shell, normally magnetised to strength $P_0/4\pi$. For, if I be the vector magnetic moment of a small magnet, its potential at Q is $-If$; in the present case $I = NP_0/4\pi$, and $P_0/4\pi$ is the moment per unit area. It is the same as Maxwell's "current function" of a current sheet. Test (32a) by the Convergence Theorem. The indeterminateness of P_0 as per (31a) as regards a constant does not affect (32a), the external potential of a closed magnetic shell of uniform strength being zero.

The external P in terms of the Surface P_0.—Let it be the surface P_0 that is given, not H_0 the surface force. A part of P is known, viz., the second term on the right of (32a). But the first term being in terms of the force, through σ, must be got rid of. Let x denote the operator that finds the external potential of the magnetic shell, that is, $x = -\Sigma(fN)/4\pi$ operating upon P_0 finds xP_0 the external potential of the shell of strength $P_0/4\pi$; this potential xP_0 is not the same as P. Let x_0P_0 denote the surface value of xP_0, not the same as P_0. Then we may denote by x_0^{-1} the operator which, acting upon P_0, finds $x_0^{-1}P_0$ the strength of shell whose potential *is* P_0 at the surface. Then, at an external point,

$$P = xx_0^{-1}P_0.$$

To render this process intelligible, expand x_0^{-1} thus

$$x_0^{-1} = \{1 - (1 - x_0)\}^{-1} = 1 + (1 - x_0) + (1 - x_0)^2 + \ldots.$$

Thus we have

$$P = x\{P_0 + (1 - x_0)P_0 + (1 - x_0)^2P_0 + \ldots\}, \quad . \quad . \quad . \quad . \quad (33a)$$

giving the external P in terms of the surface P_0 by direct operations, when for x we put its rational equivalent $-\Sigma(fN)/4\pi$.

The first approximation is xP_0. The next is $x(P_0 - x_0P_0)$, and so on. It is a process of exhaustion. But it only works when $\Sigma\rho = 0$. (33a) therefore solves the problem of finding the potential throughout a region bounded by a closed surface (taking N as the inward normal) in terms of the surface potential, the ρ and Γ being on the other side. And, when ρ and Γ are inside, it finds the external potential if $\Sigma\rho = 0$.

Annihilation of the Surface Current.—To get rid of γ and substitute matter giving the same external potential. Thus, given H_0. The first of (30a) gives H in terms of H_0 through σ and γ. The first distribution of matter is $\sigma = NH_0/4\pi$, and the force due to it is $-\Sigma f(NH_0)/4\pi$. Call this yH_0, and let its surface value be y_0H_0. Then

$$H = yy_0^{-1}H_0 = y\{H_0 + (1 - y_0)H_0 + (1 - y_0)^2H_0 + \ldots\}, \quad . \quad (34a)$$

in direct operations.

Or thus, H_0 gives a first σ and γ. Find the field due to the first γ. It has a normal and a tangential component, and

Digitized by Google

therefore gives a second σ and γ. Find the field due to the second γ, which gives a third σ and γ; and so on. As we proceed, the γ left gets smaller and smaller, and is finally annihilated, leaving a distribution of matter, the sum of all the σ's, say σ_0. Then $H = -\Sigma f\sigma_0$, where σ_0 is given by

$$\sigma_0 = N(1-z)^{-1}H_0/4\pi, \text{ where } z = \Sigma f VN/4\pi.$$

Or, $$\sigma_0 = N(H_0 + zH_0 + z^2H_0 + \dots)/4\pi. \quad . \quad . \quad . \quad . \quad (35a)$$

Annihilation of the Surface Matter, when possible.—Starting with F_0, it gives a first σ and γ, and the H due to the latter is

$$\Sigma Vf\gamma = \Sigma VfVNH_0/4\pi = wH_0 \text{ say.}$$

Let w_0F_0 be the surface value. Then

$$H = ww_0^{-1}H_0 = w\{H_0 + (1-w_0)H_0 + (1-w_0)^2H_0 + \dots\} \quad (36a)$$

Or thus; in the manner (35a) was got, but annihilating σ instead of γ, we shall have $H = \Sigma Vf\gamma_0$, where γ_0 is the finally arrived at current given by

$$\gamma_0 = VN(1-y)^{-1}H_0/4\pi; \quad \text{where} \quad y = -\Sigma f.(N/4\pi).$$

Or

$$\gamma_0 = VfVN(H_0 + yH_0 + y^2H_0 + \quad . \quad . \quad . \quad . \quad)/4\pi \quad . \quad . \quad (37a)$$

y here is the same as in (34a).

P in Terms of the Surface H_0.—When the ρ and Γ are in the inner region, the first approximation to the value of P at the external point Q is $\Sigma pNH_0/4\pi$, say uH_0; and the force due to this is $-\nabla uH_0$. The complete external potential is

$$P = u(-\nabla u_0)^{-1}H_0 = u\{1 + (1 + \nabla u_0) + \dots\}H_0 \quad . \quad . \quad (38a).$$

But if the point Q be inside, and the ρ and Γ outside, this formula does not give the internal P (with N as the inward normal), but leaves it indeterminate as regards a constant.

A in Terms of the Surface H_0.—The first approximation to A (such that $H = \text{curl.}A$) being $\Sigma pVNH_0/4\pi$, say qH_0, and the force due to this being $\text{curl.}qH_0$, the complete external A at Q, when ρ and Γ are inside, and $\Sigma\rho = 0$, is

$$A = q(\text{curl.}q_0)^{-1}H_0 = q\{1 + (1 - \text{curl.}q_0) + \quad . \quad . \quad . \quad \}H_0 \quad . \quad . \quad . \quad (39a)$$

But if $\Sigma\rho$ or $\Sigma\sigma$ is not zero, we shall have

$$H = \text{curl.}A - \nabla P_1,$$

where A is given by (39a), and P_1 is the potential due to $\Sigma\rho$ distributed equipotentially. The external energy will now be expressed by

$$\tfrac{1}{2}\Sigma A\gamma + \tfrac{1}{2}P_1\Sigma\rho$$

when $\gamma = VNH_0/4\pi$; the mutual energy of the fields of A and P_1 being zero.

Remarks on these formulæ.—The process indicated by the right member of (33a) consists in the substitution of magnetic shells for matter, and finding their potentials. Let the final result be P_1, and P_{10} be its surface value. Then $P_{10} = P_0$ if $\Sigma\rho = 0$. Otherwise, their difference must be a constant, say $P_0 - P_{10} = P_{20}$. For xP_{20} must be zero, therefore P_{20} is constant. It is the potential of the surface when the quantity of matter $\Sigma\rho = \Sigma\sigma$ is distributed over it equipotentially.

Similarly, in the (36a), (37a) annihilation of the surface matter, so far as is possible, we arrive at the force which differs from the real force by that due to the matter $\Sigma\sigma$ which is left, and which is distributed equipotentially.

It will be observed that whilst the first σ and γ together produce no field on one side of the surface, the annihilation of either completely alters this. The complete σ_0, for example, produces a field on both sides, although it is the same on one side as that due to σ and γ, *i.e.*, on the side where H was under investigation.

There is always a distinction between the external and the internal regions as regards the determination of P from the surface *force*. It fixes the external force, when ρ and Γ are inside, and it also fixes the potential, so as to vanish at an infinite distance. It also fixes the internal force when the ρ and Γ are outside, but cannot then fix the potential. (*e. g.*, no surface force, yet a constant internal potential, depending upon external matter.) This puts a difficulty in the way of the estimation of the external P in terms of the surface P_0 when the ρ and Γ are inside, and $\Sigma\rho$ is not zero, even when we apply Green's method. We do not arrive at the proper Greenian distribution of matter, but at another, giving a surface potential differing from what is wanted by a known constant, so that we have to find another distribution, to give this constant potential.

(To be continued.)

CORRESPONDENCE.

THE DYNAMO AS A GENERATOR AND AS A MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have studied Mr. Mordey's paper on the above, which you have been good enough to reprint in the current number of the *The Electrician*, with very great interest.

I observe that Mr. Mordey, after, I presume, a series of experiments with which he has not favoured us, has come to the conclusion that the construction of both generators and motors should be exactly similar, or, in other words, that given a dynamo constructed in accordance with certain now well established principles for generators, it may be used either as generator or motor by simply altering the connections or the lead of the brushes.

As this conclusion is in direct contradiction to that arrived at by Messrs. Ayrton and Perry, it would certainly be interesting to dynamo manufacturers and others who are studying the subject if Mr. Mordey would favour us with a *résumé* of the experiments he has made, or of the argument upon which he has based his conclusions.

I may say that such a result, if it should prove to be correct, will be a great boon to dynamo manufacturers; inasmuch as they will only require to keep one set of patterns instead of two.

Unfortunately, however, as it appears to me, Mr. Mordey has been singularly unfortunate, from a controversial point of view, in the account of the experiments with which he has favoured us.

He leads us to expect a certain result. He states definitely that his experiments point to that result, and straightway proves that they do not.

He states:—"A little consideration suggested the probable existence of another analogy. Since a dynamo, having the above theoretically perfect form and action, with a *constant field* (the italics are mine), would produce a constant E.M.F. if run at a constant speed, independently of the load or amount of current generated, a motor constructed on the same principles and having a constant field, if supplied with energy at a constant difference of potential, should run at a constant speed, independently of load."

Later, he says:—"The results ultimately obtained, which are given in the following tabulated account of the experiments, and in the curves plotted for them, show that this fifth analogy is as true as the preceding ones, a constancy of speed being obtained which was very remarkable."

I should here call attention to the error which I have italicised in the first paragraph. No one knows better than the author of the paper himself, that in the compound shunt-wound dynamo, arranged to maintain a constant E.M.F. at constant speed with varying current, the field is *not* constant.

The total E.M.F. furnished by the dynamo itself is not constant, and cannot be, unless the resistances of armature and main wires on field magnets are reduced to nothing, if the E.M.F. is to remain constant between two points in the circuit—the terminals of the machine. As the current increases the charge upon the E.M.F. developed increases; and to make up for this the initial E.M.F. must increase. With the speed constant, there is only one way in which the E.M.F. can be increased, and that is by increasing the number of lines of force passing into the armature; in other words, by increasing the strength of the magnetic field. Coming now to the experiments. After making the decided statement above referred to, that the motor under trial maintained a constant speed with constant E.M.F., a constant field—everything constant, in fact, which goes to make up the amount

Digitized by Google

of work done—but with a load varying from 1·8 horse-power to 16·3 horse-power in one case, and from 1 horse-power to 11·7 horse-power in the other, he proves by figures later on that the speed is not constant, but varies, more or less irregularly, inversely with the load. And then he proceeds to state that in the case of motors working with a constant field, the work done will be proportional to the speed.

I confess on reading through the record and particulars of the experiments I was very much puzzled to know how the load could be varied, everything else remaining constant.

The details given with the experiments are somewhat meagre. We are not told, for instance, what the resistance of the field magnet wires was, so that we have no means of knowing the power absorbed in furnishing the magnetic field.

Taking the experiment, however, as it is given. A pair of supply mains, from an independent source, arranged presumably to maintain constant difference of potential at their junction with the motor, the supply current dividing, part passing round the wires of the field magnets and part through the bobbin. The E.M.F. at brushes remaining constant, the current passing round the field magnet wires will be constant, and that passing through the bobbin will depend directly on the difference between the E.M.F. of supply and the back E.M.F. of the motor, and inversely on the resistance of the armature

or as $$\frac{E - E_1}{R\,a}$$

where E is E.M.F. of supply, E_1 back E.M.F. of motor, and $R\,a$ = res. of armature, in which should be included everything, such as coefficient of self-induction, which goes to reduce the working current. Now, E does not vary, $R\,a$ does not vary—in fact, such variations as would occur would reduce the current strength; therefore, the only way in which C_a, the current through the armature, can be increased is by decreasing E_1, the back E.M.F., and the only way in which the back E.M.F. can be reduced is by reducing the speed, as Mr. Mordey's experiments show. But it is surely not correct to claim at the same time constancy of speed with varying load, and under precisely the same conditions variation of speed with varying load.

The lesson which it appears to me should be drawn from Mr. Mordey's experiments is that with a dynamo constructed as this one was, viz., with a powerful magnetic field and armature of very low resistance, a small variation of speed—a variation that would be quite inappreciable in many mechanical apparatus that an electric motor would be required to drive—would give rise to a sufficient variation in the opposing E.M.F. of the motor to allow of large variation in the strength of the currents passing, and therefore of a *practically* uniform speed, with great variations in the load.

Perhaps, this is what Mr. Mordey meant to convey; but it is not the same thing, and it is not merely a play upon words. In fact, in my opinion, the distinction should be carefully remembered, if we are to avoid pitfalls in the future; and it should be remembered that it can only apply to a dynamo constructed in this way.

There are other points of great interest in connection with the experiments detailed. The very marked difference in the efficiency of the motor when running light and with a heavy load, it being greatest with the heaviest load. Bearing in mind that the work done in the armature varies as the square of the current passing, presuming the resistance to remain constant, and that both resistance and induction between the coils would increase, if anything, with the increase of current strength, we should expect to find the efficiency higher with smaller work. On the other hand, the charge for mechanical friction, and what Messrs. Ayrton and Perry have termed magnetic friction, being nearly constant for all loads, would bear heaviest on the lighter. Again, if motors of the latest improved type will only return from 30 per cent. to 60 per cent. of the electrical energy delivered to them, while generators give 80 per cent. to 85 per cent. commercial efficiency, a system of such a generator and such a motor connected together for the purpose of transmitting power would only have the same efficiency, leaving out any loss occasioned by the resistance of the connecting wires, as was obtained with the dynamo machines extant nearly eight years ago, in whose construction no thought had been taken of their acting as motors; so that in this branch, if the above is the best we can do, it can hardly be said that we have moved forward any.

With regard to the causes of the greater charge for conversion from electrical energy to mechanical energy, then from mechanical energy to electrical energy, Mr. Mordey's view that eddy currents have something to do with it is probably correct; but it can hardly account for all, as with properly constructed cores, the only path open to these eddy currents should have such a high resistance that they must be very weak; and further, if there be such a serious loss in this direction—due to powerful currents having been developed in or on the surface of the core—surely we should have the latter heated very much more when acting as a motor than as a generator; yet we find in Mr. Mordey's experiments that he was able to use a current more powerful than it was considered safe to allow when the dynamo was acting as a generator.

I should be more inclined myself to look for the loss in the interaction between the armature and field magnets, and the consequent weakness or displacement of the magnetic field.

In conclusion, I would congratulate Mr. Mordey upon having made one great step in advance in constructing a motor to perform work differing so widely in amount with such a small variation of speed. It is hardly possible to overrate this great advance in the, as we hope, approaching invasion of the industrial world by electricity as a competitor with other systems for transmitting power; and it appears to me that, assuming Mr. Mordey's figures to be correct, it is only a question of construction to reduce the variations of the speed, under varying load, and with constant E.M.F. of supply to something *absolutely* inappreciable. But such success will be due, if obtained, not to any newly-discovered law, in virtue of which any motor having a constant field will perform any work up to its full power without varying its speed, but to the special construction which enables a very *small* variation of speed to allow of the great variation of current strengths; and for showing us that this may be done, Mr. Mordey deserves our warmest thanks.—Yours, &c.

Cardiff, Jan. 19, 1886. SYDNEY F. WALKER.

THE SCIENCE OF ELECTRICAL ENGINEERING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have not, like "A Young Electrical Engineer," been so unfortunate as to come across a man in a responsible position who attempted to make electric engineering a success by keeping it as much a mystery as possible, but I have several times been surprised and annoyed to find intelligent workmen keeping back information, or even giving misleading instructions, to the *employés* of the purchasers of installations, with the idea of keeping their own firm busy.

The shortsightedness of such a course cannot be too often exposed. That there are businesses in which the plan can be carried out with success I do not deny, but electric lighting is certainly not one of them.

The sooner we have plenty of workmen to send out who can do electrical work with the same certainty and precision that other mechanical work is done, without expensive supervision, and the sooner the general public is sufficiently educated in electrical matters to know what they are getting for their money, so much sooner, I am convinced, will the electric light become sufficiently generally used to enable work to be done at reasonable prices, and not one or two, but many firms, to get a return on their capital.—Yours, &c., LUX.

January 18th, 1886.

NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly inform me what is being done by the Notation and Nomenclature Committee.—Yours, &c.,

SCEPTIC.

1885.

In concluding these somewhat lengthy notes of the past year we must again call attention to our reasons for giving them. Our object is not to prefer one company or firm to another, but to counteract as far as possible the tendency of the public to rush from one extreme to another. A few years ago the idea was universal that finality had been reached, and, because the whole community did not rush to have their houses fitted with electric light, and because local authorities were chary in introducing the system into the streets, the public opinion veered round to the idea that the whole was a delusion and a snare. Our efforts have been to show that good work is quietly and unostentatiously carried on, that the applications of electricity are not in the slough of despond, as some would have us believe. We want to strengthen public confidence in the work, in showing that good work stands the test of time, that those who have tested such work extend it more and more, to show that slowly and surely electric lighting is gaining ground, and that it will and must gain ground. We have no hesitation in saying that, so far as common sense and scientific knowledge go, it is the only light worthy of the civilisation of the nineteenth century. We are witnessing the true method of development, and, as many of our correspondents said last year and are saying again this year, the prospects are continually getting brighter. We have, as far as possible, given the information in our correspondents' own words, and it will be seen that in almost every case the outlook is held to be fairly good. We trust that the year may prove the forecast to be correct, and that in future our task may be lightened to consider more the progress from a scientific point of view than a commercial. The experience of America does not concern us so intimately as does the experience here, but it may be as well to show that our cousins across the Atlantic are progressing more rapidly, so far as installing the electric light is concerned, than we are. Of course there are many reasons which conduce to this state of affairs, not the least of which is that the cost of gas in the older towns is greater than in England, and in the more recently built places the electric light is preferred at once to gas. While we in England are talking a good deal about central station lighting, the Americans are arriving at some satisfactory or unsatisfactory results from actual experience. The following notes give the work of one of the Edison sub-companies during the past year. Our readers will see that we have retained the exact form of the notes as supplied officially to us by the Western Edison Light Company, Chicago:—

Appleton, Wis.—Central station three-wire system, 1,600 candle-power lights. Distance from central station to ends of feeders 2,100, 2,600, and 3,000ft.; total average distance from central station to lamps 5,500ft.; area covered by system is one square mile; water-power used two wheels; system enlarged recently to present capacity from 500 lights capacity; contract system.

Boone, Iowa.—Central station three-wire system, 600 10 candle-power lamps. Central station in Boone Linseed Oil Mill; power used, Reynolds-Corliss engine; distance from central station to centre of lighting 2,400ft.; plant started Nov. 4 with 500 lamps connected; entire capacity taken up now; will enlarge soon; meter system throughout; charge one cent. per lamp hour.

Rockford, Ill.—Central station, with three-wire system, 1,000 16 candle-power lamps. Power used, Reynolds-Corliss engine and New York S.S.P. Company, belted to countershaft; started with full load Dec. 31, 1885; territory covered by system 1¼ mile by ½ mile; average distance of lighting from central station is 3,000ft.; plant put in by a Van Depoele arc light company; meter system; charge one cent per lamp hour 16 candle-power, equivalent to gas at $2.00 per m.

Elgin, Ill.—Central station, three-wire system, 1,000 16 candle-power lights operated by water-power; to be started the first week in January, 1886; meter system.

Two Rivers, Wis.—Isolated plant in mills on both sides of river, 300 lamps, system covering ½ mile by ¼ mile. Lamps on other side of river from dynamo fed by armoured kerite cable which carries 110 amperes; heaviest current ever used through submarine cable; perfect success; has been in operation about six weeks; only incandescent lights fed by submarine cable in this country.

Chicago City Hall.—Two special engines, Armington and Sims, built to develop total of 225 horse-power with 35lb. steam; four Edison dynamos, having capacity of 1,650 lamps of 16 candle-power; 310 lamps operated in the two tunnels at distance of 2,000ft. from dynamos run constantly night and day; 2,200lb. of kerite covered cable and wire used in tunnels and in the underground conductors to them; 9,000lb. cable pulled in at one time and in one length from hall to tunnel; 1,300 lamps wired in City hall; total loss of electromotive force in City hall with full load 3 volts; widest variation in pressure in various parts of hall 1·2 volt. One, two, three, or four machines can be operated at one time upon the plant, and keep lamps burning in hall and tunnels. Load shifted from one engine and dynamos to the other twice a day without any variation in light whatever. Machines of different sizes run perfectly together in multiple arc. Plant started Dec. 1st, and

Digitized by Google

never has stopped a second since. It will run year in and year out.

Minonk, Ill.—Small central station, lighting a mining town, stores, and houses, light being introduced in a coal mine. It will be the first installation of incandescent lights in a coal mine in the country.

Six more central stations are to be put in in the course of the next few months. Among the isolated plants now being put in the following are given :—

	Lights.
Eastern Hospital for Insane, Kankakee, Ill.	673
National Soldiers' Home, Milwaukee, Wis.	200
United States Rolling Stock Company, Hegewisch, Ill.	671
Wm. Deering and Co., Harvester Works, Chicago	500
Pfister and Vogel Leather Company, Tannery, Milwaukee, Wis.	353
Best Brewing Company, Milwaukee, Wis. (Enlargement)	200
B. D. and W. N. Eisendrath, Chicago, Tannery and Glove Factory	150
J. V. Farwell and Co., Chicago, Wholesale Dry Goods	250
Chicago Opera House (day circuit)	75
O. F. Aldis, Chicago, Montauk Block	75
C. T. Reynolds and Co., Wholesale Paints and Oils, Chicago	150
Taylor Bros., M'Quincy, Ill., Flouring Mill	100
Wright and Lawther, Oil and Lead Manufacturing Company, Chicago	100
Crane Bros. Manufacturing Company, Chicago, Machine Shops	250
Heinemann Bros., Wausau, Wis., Mill and Store...	60
Union Elevator Company, East St. Louis, Ill.	100
C. Manegold and Son, Milwaukee, Wis., Flouring Mill	50

Central Station Totals.	Lights.
Appleton, Wis.	1,000
Rockford, Ill.	1,000
Elgin, Ill.	1,000
Boone, Iowa	600
Lockport, Ill.	400
Minonk, Ill.	300

The Electrical Power Storage Company.—During the past year probably few companies have improved their commercial position more than this company. Great hopes were entertained a year ago that the practical difficulties in connection with their secondary batteries had been surmounted, and the results have more than verified these expectations. A large proportion of the more recent installations carried out in England include accumulators, and the demand has increased to such an extent that the works of the company for some months have been running night and day. As a natural result of the extensive use of accumulators in England, confidence is rapidly spreading abroad, and among the orders in hand may be mentioned one of 100 tons supplied to the Imperial Continental Gas Association for a single installation in Vienna.

Among the batteries supplied during the past year may be mentioned those for the Society of Arts, Royal Institution, Lloyd's, H.M.S. "Vernon," Royal Engineers' Committee, South Kensington Museum, Leeds Institute, Sir R. Webster, supplied through Messrs. Crompton and Company; Lord Egerton, of Tatton; Lord Muncaster, Lord Wolverton, Sir Greville Smythe, The Electrotechnische Fabrik Cannstadt, The Nederlandesche, &c.

The company are also busily engaged in installation work, which has proved to be one of the most important branches of their business. They have lately completed, or have at present in hand, the lighting of the Prudential Assurance Company's offices with 1,500 lamps. The Bank of New South Wales, Messrs. John Bell and Sons, and private house lighting for Messrs. J. W. Logan, F. Green, H. Harben, F. Bumstead, J. Goddard, W. Alexander, &c., and have taken over the completion and working of the installation at Lloyd's, where upwards of 500 lamps will be fixed.

With the increased facilities for the production and storage of electricity, its use as a motive power is daily receiving more attention, and the Storage Company have during the past year, as the result of a long series of costly experiments, been instrumental in promoting its general application. The last tramcar manufactured by the company, which is now running successfully in Berlin, is the outcome of the experiments with the former car, which was run at Battersea in the early part of the year. The present car is fitted with the Reckenzaun gearing and Electrical Power Storage accumulators, and contains several improvements designed by Mr. Reckenzawn (who was formerly in the company's service) and the staff of the Storage Company. The experiments have conclusively shown that the accumulators are reliable for this class of work, and there is little doubt that during the ensuing year the company will be able to master the difficulties in connection with tramcar propulsion. They have built an electric launch for the Duke of Bedford, to be used in connection with the ss. "Northumbria," the accumulators being used either for propelling the launch or for lighting the yacht when the dynamo is not at work. Others are in course of construction, one of which is for the Sultan of Turkey.

An English firm that has come into prominence is that of Elwell-Parker. This firm lay themselves out for manufacturing dynamos and secondary batteries to suit every purpose for which they may be required.

To give an idea of the variety of purposes for which they manufacture dynamo machines, we may mention that during the past year they have supplied machines to Elkingtons, of London and Birmingham, amongst others, for electro-plating; to the Blackpool Tramway Company (40-unit slow-speed generators and 6 horse-power motors), for transmission of power; to the Cassel Gold Extracting Company (30-unit 1,000 ampere machines), for extracting gold from the ore; to the Trafalgar Colliery Company, Forest of Dean (6-unit generator at surface, driving 6 horse-power motor down the pit), for pumping underground; to the Cannock Chase Colliery Company, for underground lighting (carried out by their engineer, Mr. Sopwith, with perfect success); and to most of the electric light contractors for public buildings, railway stations, ironworks, house-to-house lighting, town mansions and country houses, breweries, &c., for which several hundred machines have been supplied during the year. These include machines for ship lighting.

An Elwell-Parker new 4-pole vertical machine, as supplied to Sir David Salomons for his country house, Broomhill, Tunbridge Wells, may be taken as a sample of the dynamos under notice. This machine has a 16in. armature, and, at a speed of only 350 revolutions per minute, gives 110 volts and 182 amperes. The commercial efficiency, even at this speed, is very high, showing eleven lamps (60 watts) per horse-power delivered to the pulley, whilst the wear and tear is reduced to a minimum. As far as safety is concerned, this machine may be driven at 1,000 revolutions per minute, when it would be equal to doing about 60,000 watts, but the wear and tear would then, of course, be greatly increased.

In accumulators, this firm has supplied cells which, in dimensions and storage capacity, perhaps, exceed all that has ever been attempted before; and experience in this line leads

Digitized by Google

them to the conclusion that the larger the cells the more simple and easy are they to keep in perfect order.

The action between the Electrical Power Storage Company and the Elwell-Parker Company, for alleged infringement of one of their patents, and which ultimately resulted in an injunction being granted, led the Elwell-Parker Company to experiment in a new direction, with combinations of the best parts of both the Planté and Parker patents and those of Faure, Swan, and Sellon. After careful tests, extended over a considerable period, they discovered that a Planté positive plate, prepared by the Planté and Parker patents, opposed to a negative plate of the most approved form of the Faure, Sellon, and Swan patents, combined with Moseley's separator, gave the best results yet obtained in the storage of electrical energy.

This combination was patented by Messrs. Moseley and Parker. In the opinion of this firm a decided inclination towards slow speeds and thoroughly substantial work, added to the increasing demand for larger machinery and plant, shows a very promising condition of things.

Mr. Elwell has always held to the opinion that the manufacture of electrical machinery and plant should be kept distinct from the business of electric light contractors—otherwise, competition with one's own customers must result—and he believes that eventually most installations will be carried out by those firms who have always been accustomed to install artificial light, whether it be from oil, candles, gas, or electricity.

During the past year Messrs. J. D. F. Andrews and Co. have completed a large number of installations, of some of which descriptions have already appeared in our columns. Amongst others we may mention the following:—The Cunard Steamship Company's "Umbria" and "Etruria," 850 incandescent lamps and 2 arc lamps each; H.M.S. "Ajax," 290 incandescent lamps; H.M.S. "Conqueror," 160 incandescent lamps; ss. "Corangamite" and "Burrumbeet," belonging to Messrs. Huddart, Parker and Co., of Melbourne, Australia, 160 lights each; Captain Parker's steam yacht "Lady Beatrice," 35 lights; Messrs. R. and J. Dick's boot shop, High Holborn, London, 70 lights; Messrs. Simons and Co.'s dredger "Melbourne," 6 arc lamps, &c. It may be of interest to those who have read our descriptions of some of these installations to learn that they are giving entire satisfaction, and that they have not caused the slightest trouble since they were completed. The firm had their apparatus on exhibition for the first time at the International Inventions Exhibition. They have during the year supplied a number of Andrews dynamos and other apparatus through their agents, and on their own installations, and during the last few months they have largely increased their facilities for turning out these machines quickly in order to keep pace with the increasing demand. They have also recently made some very material improvements in the Andrews arc lamp, and have obtained most excellent results from the trials that have been made. The company has been especially busy during the last months of the year, and among the work done we may mention Messrs. Geo. Smith and Son's ss. "City of Bombay," lighted with 110 lights and a duplicate set of machinery; a block of mills at Lancaster amounting in all to about 500 lights; the lighting of three passenger steamers for the North German Lloyd, with about 450 lights each; an installation of arc lamps in Mr. Houghton's steel works at Carnforth; another arc installation in a paper mill at Leslie, &c. The company have also a number of orders for the Andrews dynamos and arc lamps, and they have every prospect of more business in the year upon which we are just entering than in the past year.

Of the younger firms pushing into prominence we may mention Messrs. Goolden and Trotter, who, commencing business in March, passed a somewhat quiet summer preparatory to a very busy autumn. The works are now kept going night and day, and have orders in hand for the next three months. The firm has almost, or quite, completed the fitting of H.M.S. "Devastation," and are busily engaged on H.M. ships "Mersey" and "Severn," while ten sets of engines and dynamos are being built for torpedo boats. Some very successful experiments in train lighting have been carried out on the Lancashire and Yorkshire Railway, which are likely to assist in the development of this class of work, the railway company having already purchased several machines. The firm is making a speciality of electrical fittings and measuring instruments. It is well known also that one member of the firm, Mr. Trotter, has carefully investigated, both theoretically and practically, the question of the use of dioptric glass in the diffusion of the light from incandescent and arc lamps. We shall refer to this work in a separate article, as we shall also to the new dynamo constructed by the firm specially adapted to ship lighting.

Messrs. Thompson, Dowsing, and Rew have been giving their especial attention to the question of office and domestic signalling by electricity, and have succeeded in perfecting two very novel applications, one being an automatic indicator which can be worked entirely from the room of the person to whom the indication refers, and automatically breaks its own circuit, thereby saving wasting in the battery; the other is worked in the hall by a number of pushes (each having special reference) actuating one common indicator, the object of this latter form being to inform visitors at a glance who may be in or out without mounting the stairs, a very desirable apparatus for almost all city offices. Both indicators are independent of porter's attention, and safe from interference. This firm has also perfected some novel forms of switches, which were illustrated in our number of September 25, a very elegant departure having been made by employing glass handles in conjunction with bright brass work and slate bases. The new orange tanned belting has also met with great success, and a new form of leather rope belting has lately been placed before the public which obviates the difficulties of jointing. This firm are the English agents for M. E. Levy, who is, we understand, about to bring out a new quality of Carré carbon intended to meet requirements of certain conditions of E.M.F. and current for which the existing Carré carbons are not altogether suitable.

Messrs. W. H. Allen and Co., of Lambeth, who are the makers of the "Kapp" dynamo, which obtained a silver medal at the Inventions Exhibition, have already found a market for the useful combination of Allen engine and Kapp dynamo, ten sets having been supplied to the Admiralty, and several being in hand for private shipping firms. Besides these, the firm have supplied a large number of belt-driven dynamos for customers in England, Denmark, Germany, and Italy. Two large dynamos for the Central Station at St. Austell are also being constructed by this firm.

The Rosenthal Mirror Galvanometer.—It is claimed that this galvanometer possesses extreme sensibility with a minimum of coil resistance. We have not seen the instrument, but if the published accounts of it hold good, it will be a useful addition to the laboratory. The magnet, which is below the mirror, is placed in close proximity of distance to two low resistance coils (3 ohms each), and has a very long suspension, viz., 255 mm. Each coil is formed of 200 turns of well-insulated silver wire wound upon an ivory bobbin.

THE ANALOGIES OF GENERATORS AND MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The valuable paper by Mr. Mordey, which you published in your issue of the 8th inst., to me was very pleasing. Both Mr. Mordey and many of your readers will no doubt be interested to hear of those analogies and laws he has lately demonstrated having been practically used.

Nearly two years ago, having determined to use the Elwell-Parker dynamos as generators for transmitting power to drive underground pumps, and being at that time in search of a good motor for same, the questions arose, How should the motor be constructed to give the highest efficiency (its weight in this case being of little importance), and in what way should it differ from the generator? The matter was most carefully considered, and several experiments were made at the Trafalgar Collieries, Gloucestershire, where the machines were wanted, with the Schuckert, Siemens, and various Gramme dynamos as motors. By permission of Messrs. Elwell-Parker, at their works, I, with Mr. T. Parker, of that firm, further experimented on their machines. As we obtained a far higher efficiency than was expected, it led to a more careful investigation of the laws relating to the allied actions, during which we clearly proved the analogies Mr. Mordey now mentions. Moreover, the chief features which made that machine so efficient as a dynamo—viz., a very powerful field, with a comparatively small low resistance and highly magnetisable armature—we considered, and also practically proved, to constitute its value as a motor. Winding the armature with a single layer—thereby being enabled to obtain a most intense field, and the greatest work for the minimum length of wire, *i.e.*, lowest resistance in armature—appeared to us to be as valuable in a motor when driving a current through the field as it is known to be when used in a dynamo. Accordingly, the machines for the Trafalgar Colliery Company were built by Messrs. Elwell-Parker, the motors having field magnets of a similar shape to their dynamo, and, where compound-wound, keeping a constant field. By this mears the engineman on surface can tell by his ammeter what work the pumps below are doing. The armatures had the cores of soft iron wire carefully insulated with varnish (the top layers being of a smaller wire), and wound with a single layer of copper wire. These machines were easily reversed by reversing the current through the armature, not the slightest movement of the brushes being necessary, whether the full load was on or not. They were almost sparkless at the brushes, and have been working in the collieries ever since, running day and night, Sundays included, often working 22 hours out of 24, and are still at work, never even having had the commutators repaired. I may mention that Messrs. Elwell-Parker (with whom I am now connected) have ever since then constructed their motors on those principles. Those used at the Inventions Exhibition and also those now on the Blackpool Tramway are so built; but in the latter case the field-magnets are constructed of strips of wrought iron (Siemens type), being there limited for space and weight.

Our experience is that these machines, where properly handled, give most satisfactory results.

We did not arrive at an accurate method of determining the power absorbed by eddy currents in the motor armature, and should therefore be much interested in any data Mr. Mordey or any of your readers could furnish on this important subject.—Yours, &c., CARL T. BLANCH. BRAND.

Wolverhampton, Jan. 19, 1886.

A PRIVATE INSTALLATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Occasionally I observe in *The Electrician* accounts of large private electric light installations, and it occurs to me that it might be interesting to many of your readers to hear something of my less ambitious arrangements, particularly as I have had a long experience of the electric light, having been the first in Scotland to introduce it into a private house (in April, 1881), and that experience of a very favourable nature. The incandescent system only is employed, a Siemens S D_2 (shunt-wound) 50-volt dynamo, driven by a turbine wheel, supplying the current. The stream operating the turbine is not large, and is interrupted by thrashing operations above, so that a dam is necessary. After determining by long trial the limits of irregularity of the water supply, I two years ago adopted the present arrangement for power. From a large dam, easily formed in a sharp hollow by constructing a bank across the lower end, 8in. iron pipes are laid for about 400 yards to the turbine wheel, within 100 yards of the mansion house, and beside the home farm steading. The total fall, including 16ft. of suction, is 75ft. The turbine is of Prof. James Thomson's inward-flow vortex design, with adjustable guide blades for regulating the water supply. The axis is horizontal, and coupled directly to the spindle of the dynamo armature. To be able to derive the necessary power from half the supply of water otherwise attainable, and to avoid multiplying gearing were my objects in expending the considerable sum involved in so much iron piping. The absence of all gearing and the motion of nothing but the virtually single spindle of the dynamo and turbine, with their perfectly balanced coil and wheel, are immense advantages in eliminating almost all risk of derangement and some loss of power. The turbine is also used for thrashing, or sawing wood, by simply unscrewing four bolts connecting it with the dynamo spindle.

Bare copper cables convey the current to the bed room floor of the house, under which floor, from one end to the other, run well-covered leads, with branches to the chandeliers and brackets of the public rooms and hall below, and of the bed rooms and passages above.

The light having been introduced before there was much certainty as to its reliability, the chandeliers and brackets are so arranged that by screwing out the holders of the electric lamps, and inserting gas burners, gas may be quickly brought into use. Happily, however, this has been so far a useless provision, for from the minute of starting there has not been a single break down. Each lamp has a switch and safety fuse, and safety fuses are placed at the junctions of the branches and the mains, as well as on the main circuit close to the dynamo. A branch circuit is taken from the point where the wires enter the house to the kitchen, servants' hall, and other servants' rooms. Lights are also supplied to the laundry, stables, coachman's house, and farm courtyard.

The lamps used are Swan and Swan-Edison. The management of the installation is simple; my coachman acts as electrician. He starts the dynamo at dusk, cleaning the commutator, filling the oil cups, and pulling up the weight for closing the sluice at night, then leaving all till next day. The water is turned off from the house by an electrical arrangement releasing the weight referred to. A small wire from the house carries a current continually through a finely wound electromagnet in the dynamo room. By interrupting the current a heavy armature is released. To the screw which closes the sluice valve a wheel is fixed, round which when the valve is opened a rope attached to the weight is wound. The fall of the armature releases the weight, and the sluice is immediately closed (an improvement on this is being made, in which a hydraulic ram replaces the rope and weight). Should any severe short circuit occur, and the main fuse be melted, the armature will immediately fall and shut off the water supply. So much for the arrangement of the installation. The reliability of the electric light is sufficiently proved by the fact that, since I completed two years ago the system of power described above, there has not been a hitch in it. Its beautiful steadiness, coolness, and healthiness I need not refer to. In all these qualifications it excels gas. Regarding the interesting item of cost, the original outlay on water supply, turbine, and dynamo was much less than—about half—that of the cost of the gas works, and, as far as I can learn, the cost of wiring was about the same as that of gas pipes. The cost of maintenance has been very low. Unfortunately, I have mislaid last season's figures, which were higher than for this, owing to greater breakages of lamps. The small breakage this year is due, in part at least, to my incandescing the lamps to a lower standard than marked; but undoubtedly lamps are made now more durable. This year I spent

Digitized by Google

£5. 10s. on renewal of the commutator, which has still several months' wear in it, less than 12s. on oil and waste, and 13s. 6d. on renewal of lamps, one of which was broken accidentally. As the coachman is only occupied a few minutes a day in cleaning the dynamo, I reckon nothing for attendance. Running 25 lamps on an average from April till the middle of November, say 600 hours, the cost has been about ⅓d., or, adding interest and depreciation, about ½d. per lamp per hour. Had I run the full number of 50 lamps the cost would have been about ¼d.; and were I in the country throughout the winter much less.

These rates are thus far below those for gas in country houses, and even below those in towns. The three points I trust I have brought out in this description are the reliability, simplicity, and economy of the electric light in country houses, where water-power is readily obtainable; and there are many such houses.

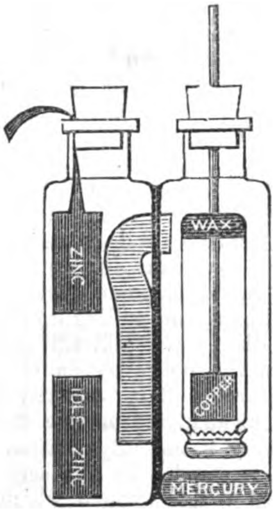
My hope is that this description may induce some of the fortunate possessors of houses favourably situated to introduce during the coming spring or summer so delightful a light.—Yours, &c., J. MARTIN WHITE.

Balruddery, near Dundee.

DANIELL BATTERY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I am obliged for your notice of my Daniell battery. I am sorry that with the description you did not get the E.M.F. of the solutions mentioned. I would like very much to know what the value of the battery would be under the conditions given. Certainly, with the dilute copper sulphate mixed with zinc sulphate the E.M.F. would be somewhat low.



I enclose a sketch of a modified form of the cell, which I find very satisfactory for a portable cell. The copper plate and copper solution are enclosed in a phial, the mouth of which is covered with a membrane. The wire from the copper plate passes through a hole in the bottom of the phial and is sealed with wax. The phial is filled with concentrated copper solution and crystals of copper sulphate. The two bottles forming the cell are cemented together, and the tube which passes through the hole in both bottles is also cemented with wax. If desired, a little mercury may be put in the bottle which holds the copper, then by lowering the copper cell into the mercury it is sealed up and diffusion prevented.—Yours, &c.,

849, W. Congress-street, Chicago, Ills. C. WIRT.
December 26, 1885.

THE ELECTRIC BOY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may assist some of your correspondents to understand the mystery of this latest "new thing" advised from the "Modern Athens" if I mention the following, to which, if necessary, I might add more.

The boy in question was born subsequent to the time of Ruhmkorff, and the wideawake showman was fully alive to the advantages sometimes afforded by a good *understanding*.

My attention was casually drawn to the matter through observing the depraved appetite of the little savage—or it may have been his family "connections," though certainly not the showman—for things not generally classed as edibles.

Your worthy correspondent, Mr. Johnstone, will quite understand me I have no doubt; and as neither of us could wish to be the means of advertising the esoteric at the expense of the penny showman's business, he will understand why I am not more explicit.—Yours, &c., HAMLET.

THE ELECTRIC LIGHT FOR IRONWORKS.

At a meeting of the South Staffordshire Institute of Iron and Steel Works Managers, held recently at Dudley, Mr. G. B. Wright, mechanical and electrical engineer, Wolverhampton, read a paper on "Electric Lighting applied to Rolling Mills." It might, he said, have been surmised that the iron rolling mills of South Staffordshire, with their low pitched roofs, would have been the last field wherein to look for the profitable use of the electric light, but experience had proved otherwise, and there were several important works where it had been adopted. Sheet iron was the staple manufacture of the district, and it might have been thought impossible to supply the roller with the electric light just where the gas jet was always essentially placed. Such difficulties, however, occurred only with the arc system of electric lighting, and had been wholly removed by the incandescent or glow lamp system. There was no better example of the successful application of this light than in the case of the extensive sheetworks of Messrs. John Lysaght (Limited), of the Swan Garden Iron Works, Wolverhampton. The whole of their works, including foundry, fitting shops, and offices, as well as pig yards, bar banks, and canal wharves, are well lighted up by means of the incandescent lamp. For sheet rolls and shears the light is all that can be required, for the stocktaker's examination it answers admirably, and for yards and wharves, though less brilliant than the arc lamp, it serves exceedingly well. The current is generated by two Elwell-Parker compound-wound dynamos. There are 380 lamps upon the two machines, 60 of them being single lamps of 95 volts, and 320 running in pairs at 48 volts. The dynamos are driven at 950 revolutions per minute by a high pressure, horizontal engine, running at 90 revolutions, and supplied by steam at 40lb., raised by the waste heat from the heating and puddling furnaces. The apparatus is in charge of an ordinary engine driver, whose wages are 25s. per week. At Messrs. E. T. Wright and Sons, Monmoor Iron Works, Wolverhampton, the system is also in use. One half of the extensive works has thus been lighted up for fifteen months past, and the installation is running as steadily now as the day it started. In this case the dynamo generating the current is, with a small engine to drive it, placed upon the top floor of the mill engine house, and the engineer for the time looks after it without much trouble. A third example is that at Messrs. George Wilkinson and Co.'s new sheet mill at Tividale. Here the dynamo is driven from the fly-wheel of a small engine, which drives a pair of edging tools for grinding, fettling, &c., and which the mill engineer also looks after. At these several works there is no provision for storing the electricity, nor has the need of it been felt. In an ironworks storage is practically unnecessary. He was in a position to speak confidently of the cost of maintenance, for in each of the examples given he had supplied the apparatus and maintained it at a price well below the cost of gas. The president opened the discussion by suggesting that if the dynamos were driven directly off the mill engine, and not by a separate engine, the lights would go out when the mill engine had to be stopped. Mr. Wright replied that generally speaking separate engines were employed. Of course, if the mill engine stopped the light

Digitized by Google

stopped. Further replying to the chairman he said that Messrs. Lysaght's installation had cost them £616. Taking the interest on outlay, and the cost of maintenance, the electric light was costing Messrs. Lysaght about one-half the expense of gas.

DYNAMO TESTS.

(Continued from page 196.)

MEASUREMENT OF CURRENT.

The currents were measured by observing the ratio of the potentials at the ends of a fixed resistance when a known current and the current to be measured were passing respectively. To do this, the terminals of a circuit containing a galvanometer and a resistance box were permanently fastened to the extremities of the fixed resistance. A current was sent through the latter, and the resistance of the box adjusted until the proper deflection of the galvanometer was obtained; the current was measured by the voltameter, tangent galvanometer, or calorimeter, and the deflection and resistance were observed. When any other current was to be measured, the box was changed until the deflection was about the same as before, and both the deflection and resistance noted. The thermometers used in getting the temperatures of the different parts of the circuit were those by Green, already described.

The notation and formulæ used are as follows:—

Let C' be the current used in calibration;
r' be the resistance used in calibration;
d' be the deflection used in calibration;
t'_s be the temperature of fixed resistance at calibration;
t'_b be the temperature of resistance box at calibration;
t'_g be the temperature of galvanometer at calibration;
C'' be the current to be measured;
r'' be the corresponding resistance;
d'' be the corresponding deflection;
t''_s be the corresponding temperature of fixed resistance;
t''_b be the corresponding temperature of the box;
t''_g be the corresponding temperature of galvanometer;
t_o be the standard temperature = 25° C.;
u_g be the temperature coefficient for galvanometer circuit;
u_s be the temperature coefficient for fixed resistance and box;
G be the galvanometer resistance;
k be the constant at 25° C.

Then

$$k = \frac{C'}{2d'} \frac{1 + u_s (t'_s - t_o)}{\left[G \{ 1 + u_g (t'_g - t_o) \} + r' \{ 1 + u_s (t'_b - t_o) \} \right]}$$

$$C'' = k\ 2a'' \left[1 - u_s (t''_s - t_o) \right] \left[G (1 + u_g (t''_g - t_o)) + r'' (1 + u_s (t''_b - t_o)) \right]$$

Calculations were facilitated by making tables of

$$G \{ 1 - u_g (t_g - t_o) \}$$

for the different temperatures, of

$$r \{ 1 + u_s (t_b - t_o) \}$$

for the different resistances that were to be used, and of

$$1 - u_s (t_s - t_o)$$

for the different temperatures of the fixed resistance.

Galvanometer.—A mirror galvanometer, by Edelmann, of Munich, was used. It was furnished with a ring magnet damped by surrounding copper blocks. The suspension, originally about two feet long, was shortened to about seven or eight inches by a copper rod passing inside the glass suspension tube; there was no trouble from vibrations. The coils were movable on graduated bars, but for the tests they were clamped and their position never changed. The resistance of the coils, with the fixed resistance and the leads to it, was

·3973 ohm, at 25°.

This was taken as G in the formulæ, and the temperature coefficient for copper used; the value of the German silver fixed resistance being only about ·0004 ohm, and the rest of the circuit being copper. The galvanometer was read with a mirror and scale, the latter being of porcelain, graduated to centimetres and millimetres. The distance from the galvanometer was 2·5 metres.

Resistance Box.—The resistance box, by Hartmann, being open at both ends and having no paraffin on the coils, was very well fitted for its work. Its measurement has been described.

Fixed Resistance.—The details of the fixed resistance are shown in Figs. 3, 4, and 5, which are, respectively, a plan, side elevation, and end view. It is also shown in perspective in

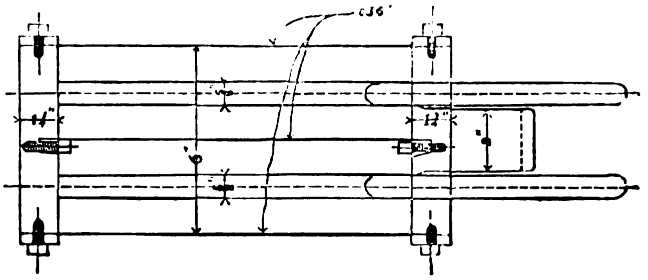


FIG. 3.—Plan

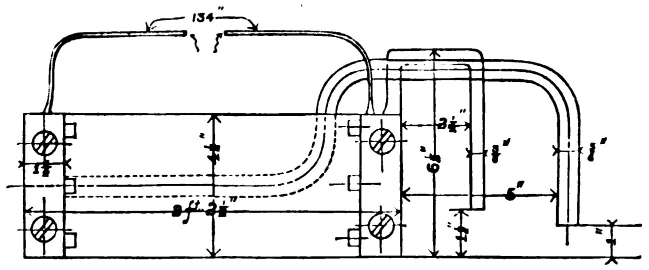

FIG. 4.—Side Elevation.

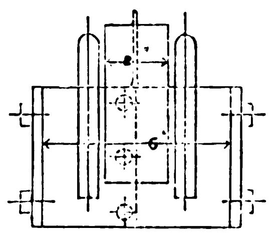

FIG. 5.—End View.

Figs. 1 and 2. It consisted of three strips of German silver, 4½in. broad by ·036in. thick, the ends hard-soldered into heavy copper blocks.

One of the blocks had a terminal piece cast on it that was bent to clear the edge of the tank in which the resistance was placed, and dipped into a mercury cup, to which one of the main leads was brought. From the other block, two copper rods passing between the strips were bent over the edge of the tank and dipped with the other main led into another mercury cup. The terminals of the galvanometer circuit were soldered into the copper blocks and remained permanent during the tests. The whole was put in a rectangular tank filled with the same kind of oil as was used for the potential resistance.

Calibrations.—Calibrations were made by sending a current through the fixed resistance, measuring it, observing the deflection of the galvanometer and the resistance in its circuit, and noting the temperatures. The calibrations usually lasted ten minutes. The constant was calculated by the formula already given.

REESE LIBRARY OF THE UNIVERSITY CALIFORNIA
Digitized by Google

Three methods of measuring current were used; the silver voltameter, tangent galvanometer, and calorimeter.

For the voltameter calibrations, a large platinum dish was used as cathode, a flattened spiral of silver wire wrapped with filter paper as anode, while a forty to fifty per cent. solution of silver nitrate was employed. With this strength of solution and with the usual current, about four amperes, the deposit was very regular and beautiful. It was treated as described under potential measurements. The resistance in the circuit was about ten ohms.

The tangent galvanometer has been already described. Two observers read both ends of the needle on each side of the zero mark. The current was reversed every minute; it varied from twenty to thirty amperes.

The method of using the calorimeter has been described. The observations give C^2 R, and R being measured by the bridge, C may be found, with the advantage that errors of observation are halved in the value of C.

Altogether, there were five calibrations by the tangent, nine by the voltameter, and five by the calorimeter. The following are the values obtained:—

·024510	by voltameter.
·024510	by voltameter.
·024440	by tangent galvanometer.
·024550	by tangent galvanometer.
·024510	by voltameter.
·024480	by voltameter.
·024590	by tangent.
	by calorimeter.
·02455	by tangent.
·02455	by voltameter.
·024481	by calorimeter.
·024477	by calorimeter.
·024520	by tangent.
·024500	by voltameter.
·024516	by voltameter.
·02453	by calorimeter.
·024495	by voltameter.
·024494	by voltameter.
·02450	by calorimeter.

This principle of measuring current has been used before, notably at the Vienna and Munich Exhibitions, but as employed in the following tests the method differs from that previously used in an important particular, *i.e.*, the construction of the fixed resistance. The substitution in the fixed resistance of German silver strips in oil instead of the copper bars in air formerly employed, increased greatly both the range and accuracy of the method.

As the method has not been commonly used, and is possibly not very generally understood, a brief discussion of the sources of error and their probable value in these tests will be given.

The possible sources of error are:—

1. In observing the deflections;
2. In the constant;
3. In the temperature correction for fixed resistance;
4. In the temperature correction for resistance box;
5. In the temperature correction for galvanometer;
6. In the values of the coils in the box;
7. In the resistance of the galvanometer coils;
8. In assuming the currents proportional to 2d.

(1.) Error in observing the deflections.

This error would enter directly in the result. The scale could be read with considerable accuracy to tenths of millimetres; the double deflections were usually between twenty and thirty centimetres. The currents measured were quite steady, but even if they varied, the excellent damping of the galvanometer would allow the readings to be taken with a good deal of precision.

(2.) Errors in the constant.

On looking at the table of constants, it will be seen that the results obtained with different resistances in the galvanometer circuit, different currents, temperatures and deflections, and by entirely independent methods of measuring current, agree so closely that their mean must be very near the true constant. Two of them, exceptional ones, differ from the mean by one-third per cent., a few more by one-sixth per cent., but the greater number are within one-tenth per cent. of the constant used. Double weight was given the voltameter calibration, as involving less possibility of error than the other methods; with two exceptions, they are within one-fifteenth per cent. of the mean. Any error would enter directly.

(3.) Errors in the temperature correction of the fixed resistance.

The uncertainty due to the temperature correction of the fixed resistance must have been inappreciable. Its temperature coefficient was small, about one-tenth that of copper, while its temperature, considering the large surface of very thin metal exposed to the liquid, must have been quite accurately known. For the heavier currents, the oil was constantly stirred. With about 400 amperes in the circuit, the thermometer registered ·1deg. C. more when held against the strip than when in the body of the liquid, while the oil rose 1·5deg. during the test. To further decrease the possibility of error, the oil was kept within at the most 5deg. or 6deg. of the usual temperature of calibration by cooling it when necessary between the tests. An error would enter directly in the results.

(4.) Errors in the temperature correction of the resistance box.

Both ends of the box were open to the air and the coils were not coated with paraffin. The bulb of the thermometer lay against or very near the coil in use. The currents could cause no appreciable heating, and the temperature of the room changed slowly.

The temperature coefficient was taken as

·0004,

and calibrations made at different temperatures showed that this was not much in error. Errors would enter almost directly in the result.

(5.) Errors in the temperature correction of the galvanometer coils.

The temperature of the galvanometer coils was given by a thermometer hung near them. With the smallest resistance used, any error in this correction would only enter as one twenty-fifth in the result.

(6.) Errors in the values of the coils in the resistance box.

The measurement of the resistance box has been described. The values were probably correct within one part in 2,000 or 3,000. Any error would enter directly in the result.

(7.) Errors in the resistance of the galvanometer circuit.

The resistance of the galvanometer and its circuit was measured by the standardised bridge. The error was probably small and entered at the most as one twenty-fifth in the result.

(8.) Error in assuming the currents proportional to 2d.

This error is slight, and was to a large extent eliminated by making the calibration on about the same part of the scale as the measurements.

The only errors then that would be appreciable are in the deflections, the constant, the temperature correction of the box, and the values of the resistance coils. The last of these could hardly have been over one-twentieth per cent.; the temperature correction of the box was probably within one-tenth per cent.

This method has several advantages. The range is very great (with the apparatus described currents of from two or three amperes to 400 could be measured with about the same accuracy) while the errors are not multiplied in the result, and are of such a nature that with proper precautions many of them can be almost entirely eliminated, and the rest made very small.

Although in measurements of both potential and current any change in H would directly affect the results, yet as certainly two, and usually more, voltameter calibrations were made for each day of the tests, and the constants were checked after each measurement, it is not probable that any important error arose from this cause.

It is also interesting to note that the magnetometer records that showed such irregularities during the life tests of lamps* just finished, were remarkably uniform during the dynamo tests.

(To be continued.)

COMPANIES' MEETINGS.

The Eastern Telegraph Company (Limited).

The twenty-seventh half-yearly ordinary general meeting of the shareholders of this Company was held on the 21st inst. at the City Terminus Hotel under the presidency of John Pender, Esq.

The SECRETARY (Mr. G. Draper) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in moving the adoption of the report and accounts, stated that the revenue for the six months ended 30th September last had been £331,420, being an increase over the corresponding period of last year of £21,851. The chief increase in the traffic had been owing to the military operations in Egypt and Rangoon. The total working expenses had been £86,935, being an increase of £1,928. The working expenses at stations had been £60,497, being an increase of £2,488. They had opened new stations at Parliament street Westminster, and at Perim. There was also a full six months' working of Katacolo and Patras, against two months of the former and one month of the latter during the same period of 1884. There also had been an increase in the number of clerks at the stations where the pressure of business was greatest. Maintenance ships' reserve fund showed an increase of £2,000. The Directors, taking the view that the ships were tools for repairing their cables, had again decided to make a special provision for this fund. He reminded them that they were able to charge the cost of the "Volta" to this fund, and he hoped that the revenue would continue sufficiently good to enable them to reserve about £5,000 each half year, so that they could apply the total cost of their new ship "Mirror" in the same way. They would then have added two ships to their fleet without having increased the capital account. That matter was under consideration. As the shareholders were aware, the object of the Directors was to keep down the capital account. The expenses attending repairs and renewals and laying of cables had been £45,288, being an increase of £14,099. Full details of work done were given in "Abstract C." The ships had been constantly employed in the half year, and in addition to the important repairs effected, the "Volta" had laid a duplicate Chio-Syra cable, and had completed the final sections of the Greek cables, which entitled them to a prolongation for ten years of the subsidy granted by the Hellenic Government. There were also included the charter, outfit, and expense of cancelling the charter of the steamship "Ardmellie." That vessel was chartered at a time when the relations between this country and Russia were very much strained through the difficulties in Afghanistan. Had war broken out it would have been absolutely indispensable to have had their ship stationed at various points beyond Suez. When political affairs became settled they cancelled the charter of the "Ardmellie" and decided to buy a new ship to be on hand for emergencies. For similar reasons it was decided to increase their tank accommodation at Perim, Suez, Malta, Gibraltar, and Syra, and they could now store over 1,500 miles of cable should the necessity arise. That put the Company in a very efficient position for the maintenance of cables under any circumstances. They could, therefore, be useful to Her Majesty's Government in emergencies such as the laying of cable expeditiously along their route. The shareholders would be aware that their Company had, on several occasions, been of special service to Her Majesty's Government and to the commanders of our Army and Navy. They had transferred the Sardinian cable reserve to the general fund, which now amounted to £429,178, the sum total of the reserve being £444,875. They were able to pay a dividend with bonus at the rate of 6 per cent. per annum, and to carry forward £32,549, or £2,180 more than a year ago. Speaking of the Conference at Berlin last year the Chairman stated that he had been there with Sir James Anderson and several members of the staff. They had a very important part to play at the Conference from the fact that the submarine telegraph companies represented at that meeting about 100,000 miles of cable, costing about £35,000,000 sterling. The whole of the submarine cables belonging to the Powers of Europe represented 7,300 miles or £1,500,000. He might also say that the value of the submarine cables possessed by the different companies exceeded the cost of the whole of the land line system represented at the Conference. They had no vote at the Conference, however, and they had to show a good case if they desired to maintain their position. At the last Conference the great object of Germany was to get something like a universal rate established for submarine telegraphy on the Continent. The German Minster of Telegraphs and Posts had been successful in establishing a uniform postal system, and he thought it was possible to introduce the same system into telegraphy; but he found that that was a very different matter. The consequence was that while he had brought the other Powers to materially reduce the rates of Continental messages, and in reducing those rates had interfered with the Company's tariff in the Mediterranean, still, after all, at the end of the Conference, the Company found themselves in this position. Reductions were made to India, involving about £23,000, and in their Mediterranean system to the extent of about £17,000. Consequently the gross amount that they had to submit to in the way of reductions was about £40,000, a large sum, which, however, he believed would be shortly recouped with the improvement of trade and the stimulus which the reduced rates would give to telegraphy. He regretted that they had had no encouragement from the Press in fighting their battles at Berlin. At some length the Chairman then referred to the desire of the British Government to establish telegraphic communication between this country and the West Coast of Africa. The Government had invited tenders for that system, and, in conjunction with the Brazilian Submarine Company, the Eastern Company had applied for the tender, and had succeeded in getting the concession, the nature of which he detailed at length to the shareholders.

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion.

The SOLICITOR then read the leading features of the agreement which had been entered into between the Government, the Company, and the Brazilian Company, relating to the proposed new submarine cable.

The motion was carried unanimously.

The retiring Directors, Lord Sackville Cecil and Lord Alfred Paget were afterwards re-elected, as were also the auditors, Mr. Henry Dever and Messrs. Quilter, Ball, and Co.

On the motion of the CHAIRMAN, seconded by the VICE-CHAIRMAN, the following resolution was subsequently carried unanimously:—

"That the Agreement submitted to this meeting, dated the 19th "January, 1886, and made between the Lords Commissioners of Her "Majesty's Treasury, of the one part, and the Eastern Telegraph Company "(Limited) and the Brazilian Submarine Telegraph Company (Limited), "of the other part, with reference to the establishment of submarine tele-"graphic communication between St. Vincent (Cape de Verde) and the "British possessions on the West Coast of Africa, be and is hereby "approved and confirmed, that the arrangements proposed by the Board "for transferring the said agreement to the African Telegraph Company "(Limited), and the subscription by this Company of a sum not exceed-"ing £75,000 to the share capital of that Company, and the raising of the "amount required for such subscription by the issue of £4 per Cent. "Debenture Stock of this Company, be also approved and adopted. And "that the Board be authorised to do all such things as they may deem "necessary or expedient on this Company's behalf to give effect to the "agreement and arrangements aforesaid."

A hearty vote of thanks to the Chairman and Directors terminated the proceedings.

[We shall publish a full report of this meeting in our next issue.]

The Brazilian Submarine Telegraph Company (Limited).

An extraordinary general meeting of the members of this Company was held at the City Terminus Hotel on the 21st inst., under the presidency of Lord Monck.

The SECRETARY (Mr. Richard Collett) read the notice covening the meeting, which was called to confirm an agreement between the Lords Commissioners of H.M. Treasury on the one part, and the Eastern Telegraph Company and the Brazilian Submarine Company on the other part, for the establishment of submarine telegraph lines between St. Vincent, (Cape de Verde), and certain British possessions on the West Coast of Africa, &c.

The SOLICITOR read the heads of the agreement, and stated that the new cable was to be laid by the 19th August next, or such extended time as the Government might think fit.

The CHAIRMAN then stated that they had been invited to attend that meeting in order that the Directors might obtain their sanction to the agreement which had just been read. It was virtually an extension of their system of telegraphy. The subject had only been brought before the shareholders within the last few days, but it had occupied the careful attention of some members of the Board for nearly three years. They understood some time in the year 1883 that it was the intention of the Government to connect the Settlements on the West Coast of Africa by telegraph with England, and as the most convenient, and, indeed, unless an independent line of telegraph were made, the only way of communicating with them was through the Company's system, they were of course deeply interested in seeing that no strangers got hold of the new communications. They had been in continual communication with the Government for over a year on the subject, and it was referred to a committee of the Board to conduct the negotiations in connection with members of the Eastern Company's Board. They would see the reason of that when he reminded them that the Eastern Company's cables constituted a portion of this Company's system, and the Eastern Company were therefore equally interested with themselves in securing the telegraph communications to West Africa. After a great deal of negotiations, about two months or six weeks ago they came to an agreement with the Government under which the Government would give a subsidy of £19,000 a year for 20 years to complete the communication between this Company's system at St. Vincent with Bathurst and the different British settlements southward to the Niger and the Cameroons. Having completed that arrangement they considered the best mode of carrying the object into effect, and they came to the conclusion, in concurrence with their allies, the Eastern Company, that the best and most convenient mode of doing it would be to start a new company, in which they should hold the shares. It was, therefore, proposed that the Eastern Company, the Brazilian Company, and the Telegraph Construction and Maintenance Company, who had also joined them, should hold the shares, but that it should be an independent company, because no one of the three allies commanded the whole line, and could not therefore work it without introducing into the management of their own concern an independent partner, which would not be convenient. All the traffic was to be conducted through the Brazilian Company's office, and their Managing Director was to be Managing Director of the new line. The Brazilian Company would have the whole of the traffic which proceeded from England over their lines to St. Vincent, and one-third of the net proceeds of all messages from St. Vincent to the West Coast of Africa. As to the financial part of the arrangement, they had thought it the best course that the Company, the Eastern Company, and the Telegraph Construction and Maintenance Company should provide the share capital of the new company by means of debentures, the three companies each providing in that way a third of the share capital. It was proposed that the balance of the cost which might be required for the new cable beyond

Digitized by Google

the share capital subscribed by the three companies should be found by the new company raising debentures of their own. The share which each of the three companies would subscribe would be about £75,000. He thought this would be a very good financial arrangement, and it was very advantageous that they should have the control of the line, so that they might not run any risk of any competitor intervening between them. It was thought when they proposed to duplicate their cable they would have to raise about £250,000 by debentures to do so; but they had succeeded in carrying out that work, and had only raised £150,000. Therefore, after paying for their share in the new cable to the West Coast of Africa, they would be £25,000 better off than they expected to be after duplicating their original system. He concluded by moving a resolution, in effect, approving of the agreement.

Sir JAMES ANDERSON seconded the motion, and stated that at first he had taken a rather gloomy view of the prospects of trade on the West Coast, but subsequent inquiries of his had caused him to take a more sanguine one. There had been a great deal of talk during their negotiations about their going on to the Cape of Good Hope with an alternative line, but he did not think our Government or the Cape Government were at all disposed at present to assist in that.

A short discussion followed in which Mr. Griffiths, Mr. Barham, and Mr. Blewitt took part.

The CHAIRMAN stated that the Eastern and Brazilian Companies were the only parties to the agreement with the Government. The Telegraph Construction and Maintenance Company were not a party to it. He had omitted to state in his opening remarks the length of line, which was 3,117 miles. The capital required for laying the cable was expected to be £460,000, of which £250,000 would be provided by debentures of the new company, and the balance, £210,000, in shares. The debentures which this Company proposed to issue would be irredeemable for twenty years, carrying 5 per cent., and would be offered to the shareholders first. He could not agree with Mr. Barham that their liabilities were very onerous.

After replying to a few more questions, he put the resolution, which was carried unanimously.

On the motion of Mr. BARHAM, seconded by Mr. G. ANDREWS, a vote of thanks to the Chairman was passed, and the proceedings terminated.

The Western and Brazilian Telegraph Company (Limited).

The thirteenth ordinary general meeting of the shareholders of this Company was held at the Cannon-street Hotel yesterday, under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and the minutes of the last meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN said that in the absence of Sir Henry Drummond Wolff, who was abroad on a foreign mission of considerable importance, the Directors decided to rotate the chair, so to speak, among themselves, and it was owing to that circumstance that he was in it on the present occasion. The duty that he had to perform, however, was not altogether a disagreeable one, because he had to draw their attention to a more satisfactory state of things, he was very pleased to say, than it had been their fortune to experience for some time. They would all, no doubt, have noted that the revenue for the year ended September, 1885, did not alone show a great increase over the income of the present year, and of the year before that, but was, in fact, the largest amount that the Company had ever earned since it began business. For instance, if they took the year 1883 (and he took it, because in 1884 there was an abnormal state of things owing to an interruption for an extended period of the cables of the Brazilian Cable Company), they found that, as compared with 1883, on the 1st of September of which year the reduction of tariff came into operation, there was an increase of 12 per cent. shown; and if they took the year 1884 there was an increase in money of £21,222, and of no less than 20 per cent. Although these figures were exceedingly encouraging, they did at one time anticipate that they should have had a still better statement to lay before them, and they could have done so but for a circumstance that was entirely beyond their control, namely, an adverse condition of the exchange at Brazil. They might have noticed, that owing to the state of the exchange, the revenue of the Company had suffered to the extent of upwards of £10,000. Of course, they would be delighted if they could devise any scheme by which that serious loss could be stopped, but, unfortunately for the present, there was, he was afrraid, no remedy, nor any immediate prospect of it, for that state of things. At one time the Company was making a profit on exchange. Therefore, let them hope they might reach a period when they would make a profit on it again. This year he could only say that they would have been another £10,648 to the good if it had not been for the unfavourable rate of exchange. Having touched upon the revenue, which he thought they would all feel was a very gratifying one, he would pass on to the expenses. They had earned 20 per cent. more money, not only without any addition to the working expenses of the Company, but with an actual diminution in them of £1,700. The total expenditure was £7,142, but of that sum no less than £1,500 would not appear in the accounts again, something like that amount having been spent last year to meet very exceptional charges. It was rather an invidious thing to do, but their acccounts had been compared with those of the Brazilian Submarine Company, and in one case a gentleman, who had compared them, and who was not sufficiently acquainted with the facts, seemed to have fallen into the very natural error of supposing that their business was more expensively conducted than that of the Brazilian Submarine, whereas the direct reverse of this was the case, their own business being much more economically conducted. The Brazilian Submarine Company had four stations altogether. One was in Portugal, one in Madeira, which might practically be said to be in Europe, one in St. Vincent, which was approximately European in point of expense, and only one was in South America. Now the whole of theirs, twelve in number, were in South America. They had the whole of the business to collect; they had all the counter work at every one of those towns in South America, and consequently they had expenses which practically did not exist in the case of the Brazilian Submarine. Then, in addition to that, they had the expense of the repairing ships, with all their stores, &c. They would imagine that under these circumstances their stations would be more expensive than those of the Brazilian Submarine Company, but the latter averaged per annum a cost of £4,000, while those belonging to this Company averaged a cost of £1,800. He thought that that comparison, looking at the amount of extra work done by them, and the more costly character of their service altogether, was a very satisfactory one to the shareholders of the Western and Brazilian Company. The London expenses of the Brazilian Submarine Company were £7,125, and those of the Western and Brazilian Company £6,933. Therefore, although there was a great deal more work in their London office, there was actually a less expenditure of £192 than there was in connection with the Brazilian submarine. It was not much, he admitted, but it was very satisfactory. There were some gentlemen present who had not been in the Company from its origin, and who were unacquainted with the condition of things that existed when the present Board took office. Then they had, so to say, a spinal cord 3,700 miles long, and of those 3,700 miles 2,700 were diseased. Then they had the old unsuitable type of strand cable. The effect of that was that they were under the necessity of keeping their ships upon the spot. It was the cause of constant breakages to their lines, of imperfect working, and of small revenues. The present directors were brought in as doctors to cure that state of matters if they could. But they had not the Bank of England at their back, and they had to proceed with caution and by degrees. But he might say that their system had been improving by degrees as their work had gone on by degrees, until at present they had reached a very satisfactory position, and could really see the end of their trouble. They had renewed of that bad stuff, extending to 2,700 miles in length, no less than 85 per cent. It had been accomplished gradually under the encouraging aid which the shareholders had given to the Directors. Unless the shareholders had had confidence in them, and supported them by their willingness to forego dividends, the work of renewal could not have been accomplished. The remainder of the cable that has still to be renewed extended to about 400 miles. Perhaps some of it was being renewed now, because the ship was out on the spot with the object of substituting a new cable for the old one, from Bahia in the south—some 200 miles—and then she would probably finish the other 200 miles that remained between Pernambuco and Ceara. Then they would have a good spinal cord from one end of their system to the other. The Directors had frequently considered the question of the ships. The strand cables and the ships went very much together, though not entirely. They must always have the ships, because they had a great many shore ends, and they had nearly 4,000 miles of cable, but the Board thought that they could do with a different class of ship, and they could therefore see their way to diminish their expenses very considerably under that head. There was, in point of fact, even this year as compared with last, which they would probably have noticed, a saving in the shipping of some £950. That might be taken as an indication that the Directors did their best to keep down the expenditure. The outcome of the legacy that was left to them would be in a year or two represented by a sheath cable all the way. Of course they could not have done the work without something in addition to the aid the shareholders gave them, and that was the renewal fund, which came in just at the nick of time, and he would say a word as to the necessity of the renewal fund. He hoped the shareholders would always back up the Board with regard to it. The boards of companies, as a rule, never wanted to put by more than was really necessary, because they were only too glad to give a dividend to the shareholders if they could. He might say that in ninety-nine cases out of a hundred Directors did not recommend the putting of more to reserve than was absolutely necessary. Certain exchanges of ideas had taken place between the Company and the authorities of Brazil and other parties interested in cable communication between this country and South America with the view of coming to some sort of working arrangement. But as yet there were no positive propositions before them. The interests were exceedingly complicated, and if any arrangement came out of the negotiations—which they must not understand him to say that he believed would be the case—it would be exceedingly difficult to bring about. Therefore, his impression was that, under the circumstances, discussion on the subject would be inadvisable. He thought they would be satisfied, when the result of those negotiations was made known, that the Directors had done the best they could for the Company. Some of the shareholders—very influential gentlemen, too—were at one time disposed to think that there was a committee named to assist the Directors in case those negotiations proceeded. They communicated with the Board in the most courteous spirit. The Directors replied, he hoped, in the same spirit, and the conclusion come to was that it was inadvisable as a matter of principle to increase the number of negotiators. He thought they had always a better chance of coming out successfully with a practical result from negotiations the fewer people there were on such committees. If they had twenty men, for example, there were pretty sure to be, more or less, twenty conflicting opinions to deal with. To sum up, their present position was—a nearly completed metal-covered cable the whole distance; the probability of lessened expenses; the certainty of a largely increased revenue which they now put before the shareholders; and the further certainty of the declaration of a dividend of 2½ per cent. if the shareholders chose to vote it. He concluded by formally moving the adoption of the report and balance-sheet.

Major WOOD seconded the motion.

Digitized by Google

A protracted discussion then ensued upon the accounts, in which Messrs. Guesdon, Swinton, Sutton, Major Cotton, Herring, Griffiths, Pyke, and others took part.

The CHAIRMAN, in replying to the various questions addressed to him, said that he need scarcely point out that the Directors in their position as the representatives of the shareholders could do nothing to commit the shareholders to the terms of any agreement without not only consulting them, but submitting the whole of the terms to them, and being ruled by their decision. All that the Board could do was to recommend to them a particular course of action. Whether they should recommend that particular course of action to a particular section, instead of to all the proprietary, was quite another question. He thought they must deal with the shareholders in a body, and not in sections, for obvious reasons. As to the item bills receivable, £26,172, that was the remittances for traffic. With regard to the expense of the insurance of the "Norseman," that was unavoidable. Travelling expenses represented the sending out and bringing home of members of the staff. It was a necessary expenditure, and could not possibly be obviated. Its amount depended upon the appointment and the removal of clerks to different places. The other item of travelling expenses was occasioned by the conference at Berlin, at which the Company had to be represented. That was an item which of course would not appear again. Their auditor (Mr. Weise) was a member of the firm of Messrs. Turquand, Youngs, and Co., a thoroughly competent accountant. A question had been very properly asked by Mr. Guesdon with respect to the repairs that had been made in their system to get rid of the old cable, and that was whether they had gone about it by the process of tender. They had done so, and they had been enabled to accept the lowest tender. There were two items of insurance. One was on account of the clerks engaged abroad, and the other for the benefit of those who were engaged in London, and the Directors, in order that the shareholders might clearly see how their money was spent, divided the item into two parts, so that they could see under which head the different amounts stood. With respect to the "Viking," she originally stood at £19,000, but they would see that she had been gradually reduced to £16,000. As regarded the negotiations he had referred to, they had been very prolonged. Very little was known about them, and the fact was that if they had from time to time communicated the character of those negotiations to the shareholders, they would simply have been utterly misled. They would have been led to expect things that would never have come to pass, and to anticipate conclusions that never would have been arrived at. But when he told them that in Brazil, during the comparatively limited period during which the negotiations had been pending, there had been six changes of the Ministry, they would at once appreciate the fact that they had to deal with a Government of a somewhat camelion like character. It had been no fault of the Directors that the negotiations had been delayed. There had been some adverse comments made as to the expenses of the administration. He could only again repeat what he had already said, that of the £7,100 there was some £1,500 of an entirely exceptional character, which would not appear in the accounts again. One gentleman regretted that they did not give a larger dividend, and another objected to the Directors' fees, which he characterised as excessive. Well, he (the Chairman) could not agree with them, for the very simple reason that the gentlemen on the Board had nothing whatever to do with the inception or with the carrying out of the business of the Company. They had had to deal with a state of things which the shareholders appeared originally to have approved, and which bore within them the very seeds of disaster. In fact, if they had not had the present Board to undo the mischief of their predecessors, he thought the probability was that the Company would have ended its transactions in a very disagreeable place. He had shown them as well as he could what the present Directors had done for them, what were the means at their disposal, and the difficulties they had had to labour under, and he thought that the outcome, namely, that they had a sound, healthy undertaking, instead of the very imperfect system they had before, was not altogether discreditable to the present Board. He was a man of business, and he did not, of course, assist in administering their affairs simply out of pure love of administration. He did so because they paid him for it, and they seemed to be satisfied with his work, and he hoped their connection might continue and be equally satisfactory to them all. As to the question of proxies, he thought they were very necessary, for the simple reason that it was only by the proxy system that the shareholders could be properly represented. It could easily be shown how inconvenient and disastrous it would be to companies if there were no such plan of getting the views of shareholders. In further reply to Mr. Guesdon, the Chairman said that Sir Henry Drummond Wolff was still a Director of the Company and took his fees, which were divided among the five members of the Board.

The SOLICITOR pointed out that the remuneration and number of the Directors were fixed by the Articles of Association, and that they could be altered only by a resolution passed and confirmed at two special meetings of the shareholders.

The CHAIRMAN, in further reply to a shareholder, said that they paid a fifth of the gross receipts in Brazil to the Platino Company.

The motion was then put to the meeting and carried unanimously.

The CHAIRMAN next moved, in accordance with the recommendation of the Board, a dividend at the rate of 2¾ per cent. free of income-tax.

Mr. D. H. GOODSALL seconded the motion, which was agreed to *nem. con.*

Major WOOD then took the chair, and in a few eulogistic remarks proposed the re-election of Mr. Andrews as a Director of the Company.

Mr. SUTTON seconded the motion, which was carried unanimously.

Subsequently Mr. Goodsall was, on the motion of the CHAIRMAN, seconded by Major WOOD, re-elected to his seat at the Board, and the auditor having been reappointed, a vote of thanks was accorded to Mr. Andrews for presiding, and the proceedings terminated.

Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held at the Cannon-street Hotel on the 15th inst., under the presidency of Mr. Hugh Watt, M.P., to consider the following resolutions :—

"That the capital of the Company be reduced by £62,500 by cancelling paid-up capital unrepresented by available assets (being patents overestimated in value) to the extent of 5s. per share upon each of the 250,000 shares which have been issued and are now outstanding."

"That the capital of the Company be further reduced by £62,500 by reducing the nominal amount of the remaining 250,000 shares of the Company's capital from 10s. to 5s. each, thereby leaving the nominal capital of the Company £125,000, divided into 500,000 shares of 5s. each."

The ACTING-SECRETARY (Mr. John Wright) having read the notice convening the meeting,

The CHAIRMAN proposed the first resolution, as above. He stated that all the old shareholders would be aware that the Company was floated under the name of the Electric Light and Power Generator Company, and that the patents for which it was formed and floated were the Rapieff, the Lontin, and the Harding. Of the value of those patents the shareholders were probably as cognisant as he. Afterwards the Directorate in conjunction, if he were not mistaken, with the promoter entered into an arrangement with the United States Electric Company or their representatives to purchase the Maxim-Weston patents. The result of those negotiations was, no doubt, to some extent, eminently satisfactory, as by the acquisition of those patents they had been placed in a position to carry on a legitimate business, for the patents which the Company had been formed to work were simply unworkable. Having, however, paid between £50,000 and £60,000 for the Maxim-Weston patents, he thought that provision ought to have been made by which the Company could obtain in the future plant from the United States Company at a much less cost than ordinary purchasers. He was glad to state that the management of that company in America had met him so far in a very handsome way, on the representations which he had made to them. On the working of the previous twenty-one months they showed a handsome profit, and for the past year they would show, when the accounts were audited and presented, a good profit, enabling them to declare a dividend in the event of the proposed resolutions being agreed to. That was one of the reasons which had led the Directors to bring the proposed resolutions before the shareholders. During the past year the working purposes of the Company had necessitated the issue of 50,000 shares, which the proprietors sanctioned in May, 1884. That capital had been placed, the limit given to the Directors being 5s. per share. There was consequently a large deficit, and he was advised by their solicitor and counsel that it would be impossible to declare a dividend until the capital had been reduced to the price of issue. Two years and nine months ago they sanctioned the issue of 27,500 shares at 5s., and the old shareholders thought that was no inducement to them, even at that price, to save their property, and his colleagues and self were forced to supply the capital. He had been very much pressed during the last year by letters from shareholders who desired a dividend, and if the Directors could have declared one without "cutting" the capital he would not have troubled the shareholders that day. It had, however, been decided by the High Court of Justice that a dividend could not be declared unless the capital were intact. The shareholders had twice sanctioned the issue of shares at 5s. each, and, of course, the Directors would not have issued above capital had it been possible for them to go on without it. All the working capital they had, however, after paying the debts of the old Company, was £2,500; and he thought they must agree with him that in view of the contracts taken, and in prospect, it was impossible for a company like theirs to go on with a capital of £2,500, competing, as they did, with companies who could make a call of 5s. or 10s. when they thought necessary, and with private firms who had come into the competition unsaddled by patents at all. Some of the old original patents had expired, and therefore, during the past year, while they had done considerably more business than in the previous year, they had probably not made a larger profit, as they had had to meet the market in price. Possibly the policy of the Board might have been somewhat fallacious, but it had been to some extent dictated by the fact that they had a large dead capital, about £175,000 having totally gone. The Directors did not wish to press the resolutions if the shareholders did not desire a dividend ; but, after all, the reduction of capital would be effected by writing down the value of the patents. He contended that the change would not affect the intrinsic value of their property, though he would not say that it would not affect its market price. The Directors had no wish to depreciate the market value of the shares, in which they were largely interested ; on the contrary, he would like to see them at a fair price; but he had arrived at the conclusion that the market value of a stock was frequently in inverse ratio to its intrinsic merits. The Directors had not been able to do all the business they could have wished in the past year, but they had done all they could to promote the interests of the Company, which he believed would in future go on steadily progressing. He concluded by moving the resolution, repeating that it was necessary it should be passed if the shareholders desired a dividend for last year.

Mr. SWABY, in seconding the motion, observed that there might be some shareholders who had joined the Company recently, and who were not very conversant with either the past or present position of the Company. He thought it very reasonable that the new shareholders might say "Why should the Directors wish to write off half the capital ?" and they might ask, equally, what the Directors had done with the half which they desired to write off. The question was very easily answered. The Directors had done nothing with the other half of the capital, as they had never had it to do anything with. If he could have his way he would go further than was now proposed. He would not only reduce the

Digitized by Google

shares to 5s., but would afterwards convert them again into £1 shares by exchanging four shares of 5s. for one share of £1, making the capital paid up £62,500 in shares of £1 instead of £62,500 in 250,000 shares of 5s. each. That, however, was only a suggestion of his, and it entirely rested with the shareholders to do what they pleased with it.

Mr. THOMAS said he feared the process of reconstruction would go on again if the suggested conversion were made, and the 5s. shares turned into others of £1. He considered that it would be to the interest of the shareholders not to reduce the capital for the mere sake of a dividend, and that if the exigencies of the business required it, they should push the business forward by means of the profit made, the shareholders waiting for a dividend. On the 31st of March, 1883, the patents were valued at £113.819.

The CHAIRMAN remarked that over £130,000 was the sum first paid for them by the late Board.

Mr. THOMAS, continuing, stated that in March, 1884, they were reduced to £70,000. That was a writing off £43,967 then for depreciation of the patents. He afterwards alluded to the remarks made by the Chairman at former meetings, and said that if there was any value in the opinions so uttered, as lately as nine months ago, he (Mr. Thomas) could not see where the value of the patents had disappeared.

Mr. GRIFFITH said he did not think it was correct to say that a dividend could not be paid when the capital had fallen below its original value. He mentioned instances of companies where the original capital was below its value—taking the value of the Stock Exchange—and stated that dividends were regularly paid by them. Putting aside this view of the matter, however, there were other objections to the resolutions. They had already reduced the shares from £1 to 10s. each. He had been glad to hear that the business of the Company had been so good that a profit had been made, but unfortunately they had not the balance-sheet for the past year before them, or they could see the exact position they were in. Supposing the resolution were wise it seemed premature to pass it until they had seen the accounts. He was opposed to it altogether.

Mr. RUSSELL thought that the shareholders must feel grateful to the Chairman and Directors for what they had done to promote the welfare of the Company, but he really thought it would be better to postpone the resolutions until the shareholders had been presented with the accounts for the past year, and he therefore proposed an amendment to that effect.

Mr. GRIFFITH said he would second the amendment.

The CHAIRMAN said that with all due deference to Mr. Griffith's professional opinion, he had been advised, and from having examined the judgments which had been delivered he asserted, that no dividend could be declared by a Company in their position without personal liability attaching to the Directors. It was of no use maintaining their patents at a fictitious sum. He did not go from the remarks he made nine months ago, but he quite agreed that the hopes he then held out had not been fully realised. At that time companies were drifting into liquidation, and the prospects were that the Maxim-Weston, with a few others, would remain alone in the field. By other companies going into liquidation, however, thousands of dynamos had been thrown on the market, and the result had been of necessity to lower the price of the plant of the Company.

Mr. JOHN NEWTON said that he had become a shareholder, although he knew nothing about the Company, but when he heard that a proposal was to be made to reduce their shares to a sum which would represent their capital he immediately bought ten shares. He had devoted the last seven years of his life to studying the question of paying dividends out of capital; and he maintained that a company could not legally pay a dividend unless their assets represented their capital. He supported the proposed reduction, and expressed his belief that the price of the shares would advance on the payment of a dividend.

Mr. THOMAS said he objected altogether to the payment of a dividend in the present condition of the Company.

Mr. GRIFFITH said it was true that outside creditors could come against Directors who paid a dividend out of capital; but the Chairman had stated that upon the trading of the last twelve months a dividend had been truly earned. He still kept to his opinion that the shareholders had the power to accept a dividend, and that there would be no danger to the Directors in paying it, but that was on the supposition that the Company had no outside creditors whose debts were unpaid.

The CHAIRMAN stated that on the 31st of December last the Company had about £12,000 cash at the bank, and some £12,000 was owing to them, about one-third of that amount being due from the British or Colonial Governments. On the other hand, the Company owed perhaps as little as £300 or £400, he could not say exactly. He believed that Mr. Griffith's view was correct, provided that every shareholder agreed to accept the dividend, and passed the resolution; but one dissentient shareholder could take exception to the whole proceeding, and render the directors liable for the amount paid.

A SHAREHOLDER expressed his belief that the Company would be damaged unless the shareholders agreed with the course proposed by the Directors. In his opinion it was merely writing off a nominal sum.

The CHAIRMAN repeated that they were not affecting the intrinsic value of the property. He only asked them to reduce to £35,000 the sum of £85,000 now standing to the debit of patents. As to adjourning the meeting, at that time there was a good deal of work on hand, and he thought the Directors could devote their energies to better purpose in the interests of the Company than to hold an adjourned meeting. He was very desirous that they should come to a decision that day. As to the remarks made about the declaration of a dividend, he would remind the meeting hat there were some who had invested their all in the Company, and to whom a dividend would be of great importance. There was no doubt that if they distributed, say, £3,000 to £4,000 in dividends they would have so much less in hand to work with, but he intended to propose—so as to prevent the possibility of paying too much away—that they should pass not less than £2,000 to reserve fund. In reply to further questions, he stated that they had greatly improved on the Maxim and Weston patents. If the resolution were not passed, it would virtually mean no dividend for two years. There was no power at present to issue any more shares, but possibly at the general meeting he might ask them to authorise the Directors to issue, as and when required, a further 50,000 shares. If so, however, it would be in connection with a matter which would place the Company on a very different footing.

Mr. RUSSELL eventually withdrew his amendment, and

The CHAIRMAN then put the original motion, which was carried. Continuing, he proposed the second resolution.

Mr. JOHN BROWN (a Director) seconded the motion, which was carried.

On the motion of Mr. GRIFFITH, seconded by Mr. RUSSELL, a vote of thanks was passed to the Chairman, and the proceedings then terminated.

LEGAL.

Oliver v. British Telephone Company.

On Monday last, at the Southwark County Court, Judge Holroyd and a jury were engaged in hearing a case in which Mr. William Wilcocks Oliver sued Mr. George Driver, manager of the British Telephone Company, and Messrs. Burt, Boulton, and Haywood, contractors, for £50 for wilful trespass upon the roof of plaintiff's premises, 15, Dockhead, Southwark, and placing thereon in 1881 telephone poles and wires without his knowledge or consent, and in so doing injuring the premises. Mr. Overend appeared for the plaintiff, and Mr. Spokes for the defendant.

The plaintiff, in the course of his examination, stated that his roof was very much injured, and he could not let the upper part of his premises for nearly four years, when he found that the defendants had caused the mischief through the General Post Office.

The defendants practically admitted their trespass, and paid £9 into court, and evidence was given on both sides as to the extent of the plaintiff's loss.

In the end the jury found a verdict for £20, inclusive of the sum paid into court.—Costs were allowed.

NOTES.

QUEENSLAND.—This colony has £250,000 to spend on telegraphs.

THE LATE STORMS.—The American telegraph system seems to have suffered severely from the late storms.

THE CENTRAL STATION AT TOURS.—We hear that the central electric lighting station at Tours has been formally inaugurated.

THE AMERICAN TELEGRAPHS.—Advices from Philadelphia state that telegraphic communication with San Francisco has been resumed.

THE STRAITS SETTLEMENTS.—Advices from the Straits Settlements state that a telegraphic line has been opened from Hue to Tourane.

THE TELEPHONE IN FRANCE.—It is announced that the telephonic service between Rouen, Elbeuf, and Louviers will be opened on the 1st proximo.

THE ELECTRIC LIGHTING ACT.—Mr. Stanhope will shortly bring in a Bill to amend the Electric Lighting Act. Mr. Hugh Watt also notifies similar action.

PERSONAL.—The Khedive has conferred the rank of Bey upon Mr. Charles Clarke, C.M.B., in recognition of his services in the Egyptian Telegraph Department.

TELEGRAPH MATERIAL FOR CHINA.—During the year 1884 telegraph wire and apparatus of British manufacture to the amount of £33,296 was exported to China.

A NEW LAMP.—It is said that the Actiengesellschaft für Feilenfabrication of Berlin are about to bring out a new incandescent lamp, to be called the "Berlinoise."

AN INTERESTING PAPER.—On the 20th proximo M. Pellat will read a paper before the Association Scientifique de France upon "Electric Machines Past and Present."

IN THE EAST.—A telegram from Constantinople, dated January 20th, announces that telegraphic communication between Philippopolis and Andrianople will be re-established in a few days.

THE QUADRUPLEX TELEGRAPH.—The American Commissioner of Patents has recently decided that the first and original inventor of the quadruplex telegraph is not Edison, but Dr. Henry C. Nicholson.

THE INDIAN TELEGRAPHS.—The telegraph service of India included in 1883, 21,740 miles of line, 62,830 miles of wire, 130 miles of cable, 324 offices, with 1,810,906 messages, yielding a revenue of £545,315.

TELEGRAPH MATERIAL FOR THE CAUCASUS.—A telegram from St. Petersburg, dated Jan. 23, says it is announced to-day that orders were recently given for the formation of a second depot of military telegraph material in the Caucasus.

REPAIRING CARBON FILAMENTS. — Our contemporary, *Electricité*, announces that an electrician of the firm of Ganz and Co. has discovered a means of repairing the carbons broken in incandescent lamps and rendering them fit for service.

ELECTRIC LIGHTING OF A MANSION.—Burtonhill, Malmesbury, the residence of Col. Miles, M.P., is to be lighted by the electric light; about 150 lamps will be employed. The work has been entrusted to Messrs. A. R. Sennett and Co.

THE LIGHTING OF TAUNTON.—The Taunton Electric Lighting Company has been formed for the purpose of lighting the town according to the Thomson-Houston system, and the provisional directors have commenced canvassing the town for consumers.

A LECTURER'S SCALE.—The current issue of *L'Electricien* contains an account of a galvanometer scale specially devised for lecturing purposes. There are two forms of this scale, one transparent and the other opaque. But few points of novelty are, however, presented.

OPTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—On Thursday last the following papers were read before the members of this society:—Dr. Thomas Reid: "Opthalmoscopes adapted for Electric Light;" Mr. H. Juler: "Refraction Opthalmoscope arranged for the Electric Light."

THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 22nd inst. amounted to £3,087. The Company give notice that the coupons on their Five per Cent. Debentures, due 30th inst., will be paid on and after that date at the Alliance Bank.

GRAVET'S SLIDE RULE.—We are informed that this rule has during the past year found a large sale amongst the electrical world and in the science and technical schools and classes. The authorities at South Kensington have adopted it generally throughout their classes, and now recommend its use to all engineering and electrical students.

THE ROYAL VISIT TO CHESTER.—On the occasion of the recent visit of H.R.H. the Prince of Wales to Chester, Eaton Hall, the residence of his Grace the Duke of Westminster, whose guest the Prince was, was lighted by the Electrical Power Storage Company, who sent E.P.S. accumulators fully charged from their works at Millwall.

PROPOSED CABLE BETWEEN AMERICA AND AUSTRALIA.—A telegram from New York, dated January 25th, states that two gentlemen from Australia, one of whom has already arrived at San Francisco, and the other is on the way, will shortly proceed to England with the object of promoting the scheme for laying a telegraphic cable between San Francisco and Australia.

THE BROOMHILL OBSERVATORY.—A provincial contemporary says:—"A most conspicuous object for many miles around Southborough is now the new electric light, equal to 15,000 candle-power, which Sir David Salomons has lately erected on the summit of his lofty astronomical observatory tower. Its effects over the snow-covered country last week were specially brilliant and vivid."

AMERICAN STATISTICS.—According to the quarterly report of the Chief of the Bureau of Statistics, Treasury Department, relative to the imports, exports &c., of the United States, for the three months ending 30th September, 1885, it appears that the exports of instruments and apparatus for scientific purposes, including telephone, telegraph, and other electric material, amounted to $88,635 as against $102,348 for the corresponding period in 1884.

THE BEST PROTECTION.—The tomb of the late Mr. H. Vanderbilt, at New Dorp, Staten Island, is guarded night and day by a corps of detectives. The niche in the vault in which the coffin of the dead millioniare is placed is connected with an electric alarm, and even if a tunnel could be driven to the tomb, any attempt to remove the body, or any tampering with the wires of the alarm, would be made known immediately at the head-quarters of the guards.

THE INVENTION OF THE SPEAKING TELEPHONE.—Our American namesake is of opinion that the Meucci story is simply a new version of the Drawbaugh claim, and one which cannot fairly be said to be in any respect more credible than that.

Digitized by Google

As regards the contest in the Patent Office between Eccard and Drawbaugh, to determine the question of priority of invention of a certain form of telephone in use in the Signal office, the examiner has decided Drawbaugh to be the prior inventor.

The Institution of Civil Engineers.—There will be a students' meeting on Friday, January 29th, at 7:30 p.m., when a paper will be read on "Electrical Measuring Instruments," by Llewelyn B. Atkinson, Stud.I.C.E., Dr. John Hopkinson, F.R.S., M.I.C.E., in the chair. An ordinary meeting will be held on Tuesday, February 2nd, at 8 p.m., when the paper to be further discussed will be "The Injurious Effect of a Blue Heat on Steel and Iron," by C. E. Stromeyer, Assoc M.I.C.E.

Another Coincidence.—Messrs. Duff and Rowntree, write to inform us that, having regard to our note of the 8th instant relative to the introduction of the electric light into Singapore by Mr. Wells, who introduced gas into the same colony about twenty-four years previously, their electric light plant is situated within a few feet of the first gasometer put down in Bishop Auckland some fifty years ago, and that the grandson of the person who put in the gas apparatus has now charge of the electric lighting machinery.

Painful Accident.—An unfortunate accident occurred recently at Messrs. Rollo's engineering works, Liverpool. Christopher Edwards, who had charge of the electrical apparatus with which the place is fitted, had just replaced the carbon burner, when a lamp fell upon him. He was picked up insensible and taken to the hospital, when it was found he had lost his eyesight. A fellow workman dreamt the night before that Edwards was handing him a battery, when it knocked him down, and he was carried away insensible.

The American Patent System.—The author of an article upon the American patent system has come to the conclusion that the money derived from patent fees ought to be expended in furtherance of the patent system. As it is, whatever is collected in the way of fees is covered into the common treasury of the Government, and whatever is expended is grudgingly appropriated by Congress. The result is a handsome balance to the credit of the Patent Office, but the plan is greatly opposed to the best interests of the patent system and to inventors in general.

A Complimentary Dinner.—We hear that Edinburgh intends to entertain the Right Hon. J. H. A. Macdonald, Q.C., LL.D., M.P., Lord Advocate of Scotland and a distinguished Associate of the Society of Telegraph-Engineers and Electricians, at dinner on the 6th proximo. Mr. Macdonald, it will be remembered, is the inventor of the "Holophote Course Indicator," and has received medals at the Crystal Palace Electrical Exhibition, and at the Inventions Exhibition, as well as an honourable mention at the Exhibition of Appliances for Saving Life which was held at the Agricultural Hall.

Domestic Electric Lighting.—Messrs. Henry Bennett and Co., of Glasgow, have recently fitted up an installation at Underwood House, Denny, the residence of R. Brown Smith, Esq., of Messrs. Smith and Wellstood, the well-known stove manufacturers. The installation consists of an Elwell-Parker dynamo, thirty 20 candle-power lamps, and twenty-five "E.P.S." accumulators. The machine is driven by a Tangye engine, which is also used for pumping water for household purposes. The fittings and globes are of a very neat design, and when the current is switched on the result is very effective.

False Telegrams.—The following notice has been issued by command of the Postmaster-General :—"Numerous advertisements having been issued in the form of fictitious telegrams, and many complaints having been received on the subject, the Postmaster-General thinks it right to call attention to the fact that the printing or circulation of fictitious telegram forms or envelopes, or of any document or form which is an imitation of a Post Office form, is an infringement of the sixth section of the Post Office (Protection) Act of 1884, and that any person acting in contravention of that section is liable to prosecution."

South Australia.—The new Loan Bill for £1,343,900, which was introduced into the Assembly on December 1, includes a sum of £17,400 for telegraph and telephone extension. The second reading of the Bill came on for consideration on December 8. The Loan Estimates were subsequently passed at £1,344,145, and a statement of excesses upon the Loan Estimates for 1884 was passed at £96,378. A handsome arcade, occupying the depth of two acres of land leading from Rundle-street to Grenfell-street, and illumined by the electric light, was opened by His Excellency the Governor on December 12.

Edison's Latest.—Edison is now said to be perfecting the phonograph. He is going to do away with shorthand writers in commercial offices. The first machine will have a five foot cylinder and be driven by steam. The sound will be transferred from the phonograph to a cylinder forty times its diameter, making the sound forty times louder than the human voice. It will have a funnel 30ft. in length. The next instrument will be for office use. Business men will dictate to the phonograph, and then hand it out to dictate to the office boy. This form of the apparatus will be self-acting, working with a spring.

Fire at Silvertown.—Soon after nine on Sunday morning an alarm of fire was raised at the India Rubber, Gutta Percha, and Telegraph Company's premises at Silvertown, and it was found that the lower part of a large four-floored building had become involved. Two rooms on the ground floor, which were used as an instrument room and lavatory, had caught fire and got well alight. The *employés* of the premises got four of the hydrants fitted to the place into operation, but although they succeeded in cutting off the spread of the flames to the upper part of the building, they could not prevent severe damage being caused to the lower portion.

Christmas Tree Lighting.—During the late festivities Mr. Penruddock successfully lighted a Christmas tree at Salisbury with fifteen 2 candle-power incandescent lamps and three chromozone cells.—At an entertainment given by the Glasgow Board of Lunacy at their Bothwell District Asylum, the Christmas tree was lighted up by Messrs. Henry Bennett and Co., of Glasgow. The installation consisted of twenty 20 candle-power Woodhouse and Rawson lamps, supplied by current from a Groves patent dynamo. The entertainment was brought to a close with a dance, the position of the lamps being altered to light up the hall.

Electric Lighting at the International Food and Cookery Exhibition.—At the recent Food and Cookery Exhibition, held at the Royal Aquarium, the stalls and exhibition were lighted by means of incandescent electric lamps. In many instances the material of the stalls was of a very inflammable nature, being composed of painted canvas, and containing lace curtains and ornamental paper in which the employment of any other than the electric light was inadmissible. In the table decoration competition it played an important part, the effect of the lamps placed among the fruit and flowers, and also on the trees in the apartments, being extremely pretty.

Digitized by Google

Upwards of 150 lamps were employed, the work being carried out by Messrs. A. R. Sennett and Co., Hatton-garden.

THE METROPOLITAN FIRE BRIGADE.—The annual report of the chief officer of the Metropolitan Fire Brigade on the state of the brigade for the year 1885 shows that during the year there has been some development of means of communication, and now the following lines are in working order. Orders have been issued for the completion of the system, and it is probable that within the next few months the whole of the work may be executed:—28 telegraphs between fire stations, 38 telephones between stations, one direct fire alarm between stations, 42 alarm circuits round fire stations with 263 call points, three telegraphs to police stations, 18 telephones to police stations, 13 telegraphs to public and other buildings, 20 telephones to public and other buildings, and 13 direct fire alarms to public and other buildings.

ELECTRIC LIGHT AT THE THARSIS SULPHUR AND COPPER COMPANY'S MINES, SPAIN.—Messrs. Henry Bennett and Co., of Glasgow, have recently completed an installation of arc lamps at the Calânos Mines, Spain, belonging to the Tharsis Sulphur and Copper Company. The dynamo used is a Crompton 6-unit machine, and supplies current to six Crompton "D D" arc lamps of 3,000 candle-power each, driven by an 8 horse-power semi-portable Marshall engine. The object of the company in adopting the electric light is to enable them to work a night shift at their excavation work, so as to get down to the copper ore as quickly as possible. The installation is of a very complete nature, and was carried out in a highly creditable and satisfactory manner by Mr. A. W. Hine, one of Messrs. Bennett's electricians.

BOOKS RECEIVED.—"School Electricity," by J. E. H. Gordon, B.A. Camb. (London: Sampson Low, Marston, Searle, and Rivington.) A concise and useful work dealing with electricity as a practical rather than a theoretical science. Invaluable to students.—The Calendar of the University College of South Wales and Monmouthshire for the third session (1885-86). (Cardiff: Daniel Owen and Co.) A perusal of this calendar, really an extended syllabus, leaves one with a pleasant impression of the thoroughness of the University. The course is unusually comprehensive and complete, more especially as regards the Physics section. In connection with this latter an excellent laboratory and workshop has been provided, and here the students are given a thorough training in physics, or general and electrical engineering in particular.

OVERHEAD WIRES AND LOCAL BOARDS.—At a recent meeting of the Camberwell Vestry, a letter was received from the Wandsworth District Board of Works, suggesting that the several road authorities of the metropolis should ascertain and record the particulars of all cases of wires being broken in their respective districts during the recent snowstorms, with a view of the information being used in the event of the introduction into Parliament of a Bill authorising the construction of overhead telegraph and telephone wires. The committee recommended that the suggestion should be complied with, and the surveyor be instructed accordingly, in view of the proposed action of the Metropolitan Board of Works with regard to the question. The recommendation was adopted. A letter was also received from the Metropolitan Board of Works on the subiect, making a similar suggestion, with a view of measures being taken to secure greater safety to the public, which was referred to the General Purposes Committee.

THE POST OFFICE CORPS.—The annual prize distribution of the 24th Middlesex (Post Office) Rifles took place on Saturday evening in the Guildhall, when the winners received their awards from the hands of Princess Mary (Duchess of Teck), who was accompanied by the Duke of Teck and the Princess Victoria. The Lord Mayor presided.—Lord John Manners said the manner in which the Post Office and the Telegraph Volunteers had discharged their important duties was on record. He had had the privilege as Postmaster-General of communicating to the colonel in command the official commendation of the General in command of the Expedition to the Soudan of the manner in which upon a recent occasion the Volunteers of the Post Office and Telegraph Departments had discharged their duties. Those duties were performed in a manner highly efficient and entirely satisfactory to the military chiefs under whom they were rendered, and in that performance the members of the regiment encountered very real dangers and perils.

TELEGRAPHIC COMMUNICATION BETWEEN LIVERPOOL AND THE CONTINENT.—On the 25th inst. a deputation waited upon the Postmaster-General from the Liverpool Chamber of Commerce, the Liverpool Cotton Association, the Underwriters' Association, and other local commercial bodies, to urge upon him the necessity for more direct telegraphic communication between Liverpool and the Continent. The deputation was accompanied by several members of Parliament. Mr. Smith, the Chairman of the Chamber of Commerce, stated that what they really wanted was that they should be able to telegraph from Liverpool to the Continent after the markets were opened, and to receive a reply before the markets closed the same day. The Postmaster-General, in reply, reminded the deputation that the matter rested partly with the Cable Companies, in concert with whom, however, the Government was desirous to act, so as to facilitate the communication. He hoped that before long direct telegraphic communication might be established between Liverpool and Havre. He would carefully consider the representations made, and hoped that the Government might be able to effect the desired improvement.

ELECTRIC SIGNALLING FROM BALLOONS.—By direction of the War Office, experiments in army signalling of a novel and interesting character were begun on Saturday evening last at the Army Signalling School, Aldershot, under the superintendence of Major Thrupp, when Mr. Bruce, son of Major-Gen. Bruce, attended to exhibit his balloon signalling apparatus. The balloon holds between 4,000 and 5,000 feet of gas. The interior is illuminated by six incandescent lamps of about 15 candles each, which can be increased up to 100 if necessary. A 25-cell battery was used, and the signalling was carried on by means of a key similar to that used on telegraph instruments, which charged the lamps for short and long periods. The balloon, which was made captive to a stake driven in the ground, ascended about 500ft., and a party of signallers having been sent out some miles away from the camp, several messages were sent and read by the signallers and replied to by the limelight, under very unfavourable atmospherical conditions, it being very foggy and snow falling the whole time. The light was also tried outside the balloon. It is understood that further experiments with this system will be carried out.

PRESCRIBING BY TELEGRAPH.—It is said that some of the operators in the service of the Western Union Telegraph Company at New York are graduates in medicine. It recently happened that one of them had his attention attracted by a message which stated that a certain physician at a place three miles distant was wanted immediately to attend a young person who had just swallowed an ounce of laudanum. The student-operator asked at once for all the particulars, and on receiving them a consultation was held at the New York office.

Digitized by Google

It was decided that it would be hazardous to postpone treatment until the doctor could be found and driven three miles to attend a patient in so dangerous a condition. The council therefore telegraphed the operator at the office nearest to the patient's residence to see that powerful emetics were administered, suggesting home made ones, such as lukewarm water and mustard and water, after which the patient was to be vigorously rubbed and whipped with switches to prevent sleep. This unexpected order was faithfully carried out, and with such happy results that the poison failed to act. Something like this was done, if we mistake not, at Manila about a year ago.

Military Mines.—At a meeting of the Royal United Service Institution, held at Whitehall-yard, on Wednesday last, Major Sale, R.E., read a paper on "Land Mines." The lecturer, in opening his address, said that he did not propose to touch upon that branch of military mining which involved the use of shafts and galleries, and such like subterranean warfare, but rather to deal with that class of small surface defence mines which might be more properly termed land torpedoes. In the recent operations at Suakim mechanical mines were used, and as the Arabs showed the most extraordinary keenness in detecting any kind of tripping wire or safety line, the torpedoes were set to explode when trodden on, and without safety lines for recovery. Briefly, it might be said that mechanical mines were unsatisfactory, imperfect, and decidedly dangerous, and should not be used except under very special circumstances. Upon the whole it appeared to the lecturer that the advantages to be gained by the use of electricity so decidedly preponderate over the drawbacks, that this mode of firing land mines should in almost every case be preferred to mechanical methods. Commander Kingscote said that in the Zulu war they had found land torpedoes most useful. For ordinary purposes the mines must be electrical, but in warfare against savage nations mechanical mines were very useful in fighting the natives.

A Telephone Exchange at Keighley.—After a considerable time spent in negotiations the National Telephone Company have at last opened an exchange at Keighley. During the course of the inaugural ceremonies Major Harrison said he was very glad that they had been able to open an exchange at Keighley. They had been in operation in Yorkshire for the past four or five years, and they had looked forward to establishing a large exchange at Keighley. They had already exchanges at Bradford, Leeds, Halifax, Dewsbury, Batley, and Wakefield. Keighley had been rather a sore point with them, because they had never been able to get a sufficient number of guarantees to justify them in establishing at once an exchange there. However, they had now been able to accomplish their object, and he trusted that Keighley would in a short time prove to be one of their largest as well as one of their best paying exchanges. These telephone exchanges had already proved to be of great service in other towns in Yorkshire, and now that the Keighley Exchange had been established he hoped soon to see it extended to Skipton. In Bradford there were already ninety private houses in connection with their exchange. To make a town exchange a success they required numbers, and in Keighley there had not yet been a sufficient number of subscribers for this purpose. He was certain that when they became familiar with the uses of the telephone that number would be largely increased.

Electric Light versus Gas.—The following letter appeared in a recent issue of the *Accrington Times*:—"In consequence of the proposed purchase of the gasworks I have been surprised that so little has been said about electric light, and as an unprejudiced ratepayer I desire to say a few words on this subject ere it be too late. It behoves the ratepayers to be careful to protect their interests, and not allow the corporation to act without a full and fair inquiry and a thorough test of the electric light. It is generally supposed that the electric light is only adaptable to large areas, and that it cannot be utilised for mills, workshops, and houses; but this is an error, as the light is now used in corn mills, woollen mills, weaving sheds, workshops, and private dwellings, and the saving in cost is as much as £200 on a place hitherto costing £300 per annum for gas at 3s. per 1,000ft. I have before me a list of fifty mills and private residences which are now using electric lamps alone at a great advantage in cost, health, and comfort, and considering the difficulties through prejudice and the vested interests of shareholders in its gigantic rival, and the short time that has elapsed since the electric light made its appearance, the progress established is satisfactory; and we should be on our guard against bartering away our freedom of action in this important matter. There is no urgency for taking over the gas works, and it were preferable to postpone the subject indefinitely rather than act injudiciously on one-sided data. Should the report of the committee recently appointed by the Council prove that its merits have been fully tested I earnestly appeal to those who have the welfare of the town at heart to claim a fair trial for the electric light before giving their countenance to what may hereafter be found an egregious blunder."

A New Thief Catcher.—Some dishonest men, whose arrest was brought about in a singular manner, have been dealt with at the Thames Police-court. The accused were James Andrews, who was charged with stealing meat, and Henry Saunders, George Turner, and Thomas Galley, who were charged with unlawfully receiving it. Andrews was a shopman in the employ of a butcher named Chapman, who for some time had missed large quantities of meat. In consequence of this he communicated with the police. Returning from market one morning earlier than usual, he secreted himself in a box, from which he could command a view of the shop. Before the shutters were taken down he saw about half a dozen men come in and receive meat from Andrews. To bring these offenders to justice he hit on a novel plan. He arranged with several detectives to signal to them from an electric light which he fixed on the top of the house, and connected with his place of concealment. Again he watched, saw Saunders come into the shop, and Andrews give him a shoulder of mutton, a piece of beef, and some sausages. On Saunders leaving with the meat, Chapman "switched" on the electric light. Two or three minutes later Turner came in. He purchased a small article, and some money passed between him and Andrews. The latter then pushed him over a large piece of mutton, which he quickly wrapped up, and went out. Saunders again switched on the lamp, and signalled the detectives. Galley then came in, and the same performance happened. Then someone came in and gave Andrews the "tip," and he left the shop, but was afterwards brought back by one of the detectives who had arrested his accomplices. The magistrate sentenced Andrews to three months', Saunders to three months', and the other two prisoners to fourteen days' imprisonment, all with hard labour.

Overhead Wires.—In the House of Commons on Monday night Sir H. Tyler asked whether attention had been drawn to the failures of telegraph and telephone wires used overhead in the metropolis during the recent snowstorm, and to the accidents which had been occasioned thereby; whether a

Digitized by Google

return of these failures and these accidents would be prepared and presented to the House; and whether any steps would be taken to prevent this constantly increasing danger to all persons using the streets of the metropolis.—Lord J. Manners replied that his attention had been drawn to the failure of telegraph wires during the recent snowstorm, and he was glad to be able to state in reply to the question of the hon. member that no case of accident to any human being has been caused by the wires belonging to the Post Office. A large proportion of the overhead wires in the metropolis did not belong to the Post Office, and the Department had no means, therefore, of furnishing the return asked for. The policy of the Post Office for many years past had been to substitute underground for overhead wires in London, and also in other large cities, wherever the extra expense involved could be justified, and since his appointment he had given renewed instructions on this point. He might add that the mileage of postal telegraph wires in the metropolis on the 31st of December was 9,832 miles, of which 9,005 miles, or about 11-12ths, were underground wires. In the eastern central and western central postal districts, which comprise the half of the metropolis, there were only 44 miles of overhead wires the property of the Department. As the House was aware, a Select Committee was appointed last session to consider the law relating to the control over telephone, telegraph, and other wires, and made a report, but it has not been considered desirable to take action in the direction of the course recommended in that report.

ACTION AGAINST A TELEPHONE COMPANY.—On the 25th instant, in the Lord Mayor's Court, before the Recorder and a common jury, the case of Harris *v.* the United Telephone Company was heard, in which the plaintiff, a dentist in the Mile End-road, sought to recover from the defendants £8. 15s. expenses he had been put to in repairing a wall which it was alleged was damaged by one of the defendant company's poles. Mr. Harte was counsel for the plaintiff; Mr. Scott for the defence.—Mr. Harte said his client was applied to some five years ago by the defendants to allow a pole to be placed in his garden, to which after a time he consented. A pole 60ft. in height was subsequently placed in a corner of it. It carried thirty-eight or thirty-nine telephone wires, and was supported by means of stays, and came within a few inches of the wall in question. For some years no rent was charged for it, but subsequently an arrangement was come to that the plaintiff should have telephonic communication between his surgery and his private house, the company agreeing to pay him £2. 10s. a year for the right and use of the garden for their pole, and the plaintiff to pay £5. 10s. for the use of the connection; the company undertaking to be responsible for the erection, maintenance, and removal of the pole. In May last the plaintiff had notice from the local authorities that the wall had become unsafe, and had to pull it down and rebuild it, at the cost now sued for. The cause, it was alleged, was that the stays having weakened the wall, made the pole lean towards it.—The learned Judge: But the pole never touched it.—Mr. Harte: No, my lord.—The learned Judge: Then the wall got frightened?—Mr. Harte: No, not frightened, except it might be said it became frightened yielding to undue pressure.—The defence was a denial that the injury was caused by the pole in any way, but that it was the result of the unsound condition of the wall.—The jury found a verdict for the plaintiff for the amount claimed.

THE ITALIAN TELEGRAPH ADMINISTRATION.—From the Italian "Yellow Book," recently issued, relating to the progress of telegraphy in the Kingdom of Italy during the year 1884, we learn the following interesting particulars:—In the course of that year 179 fresh offices were opened for public business, 80 of which were Government offices, the remaining 99 being offices made available for that purpose at various railway stations. Partly in connection with the opening of these new offices, and partly in consequence of extensions of the system, additional lines have been erected over 423¾ miles of country, with a length of wire amounting to 3,693½ miles. Adding these to the lines existing in 1883, the report shows a present total of 18,132 miles of line, representing 64,052 miles of wire. The number of offices worked by Government clerks is now 1,927, and of offices at railway stations open for the reception of public messages 988, making a total of 2,915 for the whole kingdom As regards the traffic, the increase has apparently kept pace with the improved facilities. The total number of telegrams from all sources dealt with by the Italian Administration during the year was 7,738,227, which is 561,704 in excess of the total for 1883. This total includes, of course, all telegrams, whether foreign, inland, or such as merely pass over the Italian lines from one foreign country to another. Of this total 6,260,853 were inland telegrams, being an increase of 441,843 on the previous year; whilst foreign telegrams increased by 74,680, bringing up the total of messages despatched to and received from foreign countries to 1,271,631, the remaining 205,743 messages representing the transmitted foreign traffic. The revenue for the year amounted to £495,755, against an expenditure of £399,956, leaving a profit of £95,799. This account, however, does not appear to include any estimate of cost for the transmission of Government messages. The report is signed by Sig. E. D'Amico, the Director-General of Telegraphs for Italy.

ELECTRIC LIGHTING IN BRIGHTON.—In addition to the system on the Pavilion Estate, worked under the direction of the town council, with their own plant, the Brighton Electric Light Company are now supplying power for nearly 1,000 incandescent lamps. The whole circuit extends over about eight miles, running from the central station to Preston-street on the west, along the sea front and up to Dorset-gardens on the east, and to the railway terminus on the north. This northern district circuit now simply supplies the railway station, which is lighted solely by electricity, but in a short time it will be extended to the locality of the Level and Lewes-road, and leads will also be carried on to Hove. The power is supplied on the high tension system. Brighton is the only town in England where the arc and incandescent lamps are run on the same circuit. The central station in Gloucester-road now consists of a large square newly-erected brick building. Workshops have yet to be erected in the rear, on the site of the old station. The three engines formerly used there are now in course of removal, and when the shops have been completed, all the company's repairs will be executed here, including the repairs to lamps. The engine now in use is a large compound, by Fowler, of 200 horse-power, the fly-wheels and shaft of which weigh five tons. This drives three 40 lighter dynamos, and together these are capable of sustaining a hundred and twenty 2,000 candle-power arc lamps. The machinery which generates the power now runs from dusk to 1 a.m.; but the directors contemplate adding another and a more powerful engine, so as to provide for further demands on their resources, and also in order that, if found to be necessary, the supply may be continuous through day and night. At the railway terminus alone sixteen 2,000 candle-power arc lamps are in use, and the light is also installed at the Orleans Club, the Chapel Royal, the Theatre, the Oxford Music Hall, the Aquarium, and at several hotels, restaurants, and places of business. A further enlargement of the system at the Grand Hotel is contemplated.

THE SUN—A POINT OF VIEW.

BY ALEXANDER J. S. ADAMS.

Of marvels, one of the greatest is the sun; his wonderful heat, his resplendent light, and the undiminished continuity of his glory.

How few of us more than wonder at the strange and beautiful orb; and yet there is much of intensest interest in his daily doings.

One important feature about him is the tiny looking spots that, now singly and now in groups, trip across his face, and which, at all events in the case of the larger spots, affect our globe to probably a greater extent than at first sight appears, and sometimes by exhibitions of electric force play pranks with the otherwise orderly flow of electricity upon our telegraphic systems.

Little may be known regarding the physical properties of the sun, but we should grasp to some extent the apparent meaning of the sure connection that exists between the large spots and the earth.

Sometimes it is a single spot of larger size and darker hue, at others groups of spots, small individually and ill-developed, that rush across the sun's face, although it seems that only the larger spots are found to disturb our telegraphic peace; and even they fail to produce effects upon our lines until in passing across the sun's disc they reach a position near its centre.

Thus, in April, 1882, although a large spot was clearly visible as it came round the western edge of the sun, it was not until five days later, and when the spot had reached the centre of the disc, that a violent electric storm, lasting three days, took possession of our globe. The same spot remained visible for several days afterwards, but without effecting further disturbance.

In November, 1882, a spot of considerable magnitude passed across the sun's face, and it was only during its presence at the centre of his disc that a shock of electrical disturbance visited us.

A further experience of the kind occurred so recently as January in the present year, when a large spot became visible at the western edge of the sun's disc on the 2nd or 3rd, although it was not until the 9th that for thirteen hours an electrical disturbance manifested itself.

As I write there is a group of four goodly spots at the very centre of the sun's face, which, if they were rolled into one, would in the aggregate more than equal the last single spot referred to; yet, in the case of this fine group, as in the case of similar groups, there is the remarkable difference that no electrical effect is apparent.

Surely this variance in the effectiveness of groups, as against large single spots, should teach us something; and the lesson taught by these experiences would seem to be that the causation for these shocks to our globe cannot reside upon the *surface* of the sun, otherwise the earth would feel the influence at any time during the period that the spot is visible. The seat of the outcoming force must lie at some far-reaching depth, from whence the force rays only reach the earth when the sun spot vortex directly faces us.

From this point of view, then, we will start. Known laws indicate that in the interior of the blazing sphere will be a solid body; that beneath the burning gassy exterior as viewed by us there will be a nucleus, perhaps a cool hard globe, revolving about its axis at a rapid pace and possessing magnetic power vastly beyond our computation. Around this solid nucleus, yet thousands of miles above its surface, would float an atmosphere—a metallic gassy envelope thousands of miles in thickness, not cloudy, but heated to the intensest degree by the mighty magnetic rays showered upon it by the nucleus.

The fact that a wire moving near a magnet will gather up its rays and in due time transform them into heat and light will serve as a fair illustration.

The whirling of the inner globe goes ever on, and its forces are driven forth, to be gathered up by the solar envelope and turned to heat. The heat thus constantly generated in the inner parts of the sun's envelope will be as constantly transmitted to the outer parts, and thence, by radiation, quickly dissipated, maintaining thereby those outer parts at a comparatively moderate temperature.

The condition of things would therefore be, that whilst the inner parts of the sun's envelope are composed of mixed, most intensely heated metal gases, radiation from the outside will cool and decompose the mixed gases into clouds and banks of heated metallic vapour, each, after its kind, producing the grainy, puzzling appearance so well known to astronomers.

From the action of boiling liquids we may gather the terrific struggle for supremacy that goes on between the super-heated gases of the inner portion and the cooler and more condensed parts outside—a struggle in which the underlying depth of heat may sometimes gain the mastery, and tearing upwards will distort and rend the outer covering in its career.

That a mastery of the inner over the outer portions of the envelope once gained should remain for a considerable period is not unlikely; and that such is the fact may be gathered from the frequent long continuance of individual spots.

In the case of the more considerable eruptions it is possible that the forcing aside portions of the sun's envelope will offer, for some at least of the nucleus force rays, a means of escape into space; thus it will be not enough that a sun-spot vortex be turned towards the earth to affect it, there must also be a sufficient denudation at the point of rupture to permit the force rays to pass through, and the strength of the disturbance will in large measure be proportional to the freedom of the passage provided.

It may be advanced that the necessary energy at the nucleus for so splendid a result is improbable; that such an enormous exhibition of force could not last the ages; but it should be borne in mind that although electricity and magnetism are unravelled mysteries, it would really seem not only that enormous energies may be drawn from comparatively small magnets, but that their hidden springs were also inexhaustible. A moderate computation would demonstrate that the few rays which actually strike the earth will possess an energy at the sun's surface amply adequate to the task here sought to claim for it.

THE STEAM ENGINE INDICATOR.—XIV.*

BY AMICE.

Our means of comparing an indicator diagram with the diagram which would be obtained from a steam engine were it not for practical sources of loss more or less unavoidable, but which steam engine builders do their best to make as small as possible, would be incomplete without the curve which is obtained by plotting the pressures and volumes of a given weight of steam at different temperatures. We have thus far only dealt directly with pressures and corresponding volumes of steam, temperature having been taken into consideration indirectly only, though we have referred to the condensation of steam during the commencement of the stroke of the piston consequent upon the entrance of the steam to a cylinder which has been cooled down to the temperature of the exhaust, or approximately thereto, and to the consequent fall in pressure. We have also referred to the rise in pressure of the steam during the expansion part of the stroke, consequent upon the re-evaporation during expansion of the steam so condensed, that re-evaporation taking place as the pressure falls to that under which the condensed steam will boil, and continuing to do so until exhaust takes place. It would be more correct to speak of this as a maintenance of pressure rather than a rise of pressure, as the re-evaporation does not cause a rise but retards the fall of pressure. It must be remembered that the pressure and temperature of saturated steam—that is, steam in the presence of the water from which it is evaporated—rise together, though not exactly in the same ratio. Every given weight of saturated steam has a definite volume, pressure, and temperature. That is to say, any given weight of water will give a specific volume of steam at a specific temperature or pressure. This is

* For Art. 13, see *The Electrician*, 25th December, 1885.

Digitized by Google

known as specific or relative volume. By plotting specific volumes and pressures we obtain a curve which differs somewhat from the so-called isothermal curve or hyperbolic curve, and from the adiabatic curve, and is in many cases rather nearer the actual indicator diagram than either of these. It is, however, almost as often so, partly as a result of a combination of contributing causes, including clearance, initial condensation, and subsequent re-evaporation, which in other cases may operate to make it incorrect, but inherently it is more correct as a theoretical curve than either of the others. It deals with steam as steam, and represents graphically the results of the experiments of Regnault, Fairbairn, and others, made under conditions which are very much those of the steam engine, except as to the sources of loss above mentioned. The following table gives a few corresponding temperatures, pressures, and volumes merely for convenience in dealing with the curve to which we refer, such a curve being very useful as a comparison with diagrams obtained from the steam engine cylinder.

Table C.—Relative Pressure, Temperature, and Volumes of Saturated Steam.

Pressure in lbs. per sq. inch.	Temperature. Fah.	Specific volume. Water at 40°, being 1.
5·00	162·37	4627
10·00	193·29	2429
14·68 (atmospheric)	212·00	1702
15·00	213·07	1669
20·00	228·00	1280
25 00	240·20	1042
30·00	250·40	881
35·00	259·3	764
40·00	267·3	676
45·00	274·4	608
50·00	281·0	552
55·00	287·1	506
60·00	292·7	467
65·00	298·0	434
70·00	302·9	406
75·00	307·5	381
80·00	312·0	359
90·00	320·2	323
100·00	327·8	293

The figures of the first and last of these columns set off on the vertical and horizontal scales, as in the accompanying engraving

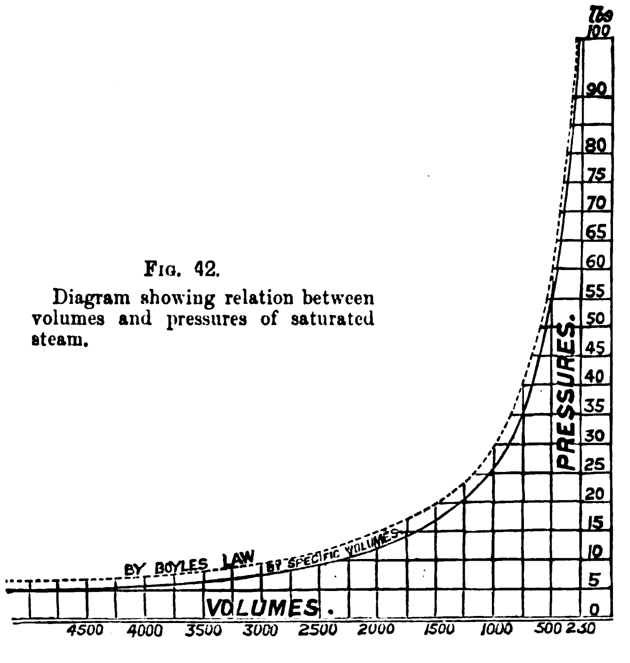

Fig. 42.
Diagram showing relation between volumes and pressures of saturated steam.

(Fig. 42), give us the curve of specific volumes, from which it will be seen that the volumes do not quite bear an inverse ratio to the pressure; and, in fact, the departure is considerable, the specific volume curve leaving the dotted curve, traced according to Boyle's law, by a perceptible distance even at the higher limits. This really is the curve we should obtain from the steam engine if the cylinder were at the temperature of the incoming steam, and fell in temperature only in accord with the fall in pressure, due to increase in volume during expansion.

CORRESPONDENCE.

ON THE RISE AND PROGRESS OF NOMENCLATURE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The importance of nomenclature was recognised in the earliest times. One of the first duties that devolved upon Adam on his installation as gardener and keeper of the zoological collection was the naming of the beasts.

The history of the race is repeated in that of the individual. This grand modern generalisation explains in the most scientific manner the fondness for calling names displayed by little children.

Passing over the patriarchal period, the fall of the Tower of Babel and its important effects on nomenclature, the Egyptian sojourn, the wanderings in the desert, the times of the Kings, of the Babylonian captivity, of the minor prophets, of early Christianity, of those dreadful middle ages of monkish learning and ignorance, when evolution worked backwards, and of the Elizabethan revival, and coming at once to the middle of the 19th century, we find that Mrs. Gamp was much impressed by the importance of nomenclature. "Give it a name, I beg. Sairey, give it a name!" cried that esteemed lady. She even went so far as to give a name to an entirely fictitious personage—Mrs. Harris, to wit—who has many scientific representatives.

Having thus fortified ourselves by quoting both ancient and modern instances, let us consider the names of the electrical units.

A really practical name should be short, preferably monosyllabic, pronounced in nearly the same way by all civilised peoples, and not mistakable for any other scientific unit. If, in addition, it be the name, or a part of the name, of an eminent scientist, so much the better. That is quite a sentimental matter; but if it does no harm, it is needless to object to it. But we should never put the sentiment in the first place, and give an unpractical name to a unit on account of the sentiment.

Ohm and volt are admirable; farad is nearly as good (but surely it was unpractical to make it a million times too big—the present microfarad should be the farad); erg and dyne please me; watt is not quite so good, but is tolerable. But what about those remarkable results of the Paris Congress, the ampère and the coulomb? Speaking entirely for myself, they are very unpractical. Coulomb may be turned into coul, and is then endurable; this unit is, however, little used. But ampère shortened to am or amp is abominable. Better make it pere; then it will do. Then an additional bit of sentiment comes in to support us. Was not Ampère the father of electrodynamics?

It seems rather unpractical for the B.A. Committee to have selected 10^8 c.g.s. as the practical unit of E.M.F., instead of 10^9. This will hardly be appreciated except by those who make theoretical calculations; the awkward thing is that the père is one-tenth of the c.g.s. unit of current. I suppose it was because the present volt was an approximation to the E.M.F. of a Daniell; that is, however, a very strong reason for making the practical unit much smaller; because the E.M.F. of a cell has now to be given in volts and tenths, or hundredths also. How awkward it would be if the ohm had been made 10^{10} c.g.s., so as to approximate to the resistance of a mile of iron telegraph wire. The ohm and volt should be the same multiple of the c.g.s. units, both 10^9 for example. Then use the millivolt or centivolt when speaking of the E.M.F. of cells. The present 1·12 volt would be 112 millivolts. Speaking from memory of reading something somewhere, Sir W. Thomson did object to the 10^8 volt at the Paris Congress.

Mac, tom, bob, and dick are all good names for units,

Digitized by Google

Tom and mac (plural, max), have sentimental reasons for adoption, bob and dick may also at some future time. I have used tom myself (no offence, I hope) for six years past to denote 10^9 c.g.s. units of self or mutual electromagnetic induction coefficient. (Some reform is wanted here. Coefficient of self-induction, or of electromagnetic capacity, is too lengthy). The advantage is that L toms divided by R ohms gives L/R seconds of time. But it is too big a unit for little coils; then use the millitom; or even the microtom for very small coils. This applies to fine wire coils. The c.g.s. unit itself would be most suitable for coils of a few turns of thick wire. If it is called the tom, then the kilotom or megatom will come in useful for fine wire coils.

A name should certainly be given to a unit of this quantity, whether it be tom, or mac, or any other practical name. Also, names to a unit of magnetic force (intensity of), and of magnetic induction.

There is also the question of the names, not of the units, but of the physical magnitudes of which they are the units, but it is too large a question to discuss here except in the most superficial manner. It is engrained in the British nature to abbreviate, to make one word do for two or three, or a short for a long word. And quite right too. We have much to be thankful for; in the application of this general remark, consider what frightful names might have been given to the electrical units by the Germans. But, on account of this national, and also rational tendency to cut and clip, it is in the highest degree desirable that as many as possible of the most important physical magnitudes should be known, not by a long string of words, but by a single word, or the smallest number possible.

Thus, I find myself frequently saying force, when I mean magnetic force, and even then, I mean the intensity of magnetic force. The context will generally make the meaning plain. But it is necessary to be very careful when there are more forces than one in question. (This use of force as an abbreviation is, of course, quite distinct from the frequent positive misuse of the word force, to indicate it may be momentum, or energy, or activity, or, very often, nothing in particular, the misuser not being able to say exactly what he means; nor does it much matter.) It would be decidedly better if such a quantity as "intensity of magnetic force" had a one-word name, for people will abbreviate, and sometimes confusion may step in. This remark applies to most of the electro-magnetic magnitudes.

There is an important magnitude, the magnetic induction. I call it often simply "the induction"; but in doing so, carefully avoid calling any other quantity "the induction" (sometimes the electric displacement is called the electric induction.) But there is an unfortunate thing here, which somewhat militates against "the induction," or even "the magnetic induction" being a thoroughly good name for the magnitude in question. This is, that besides being a name of a physical magnitude, the word induction has a wide-spread use, in a rather vague manner, in connection with transient states in general, whether of the electric or of the magnetic field, exemplified, to take an extreme example, when a man explains something complex by saying it is caused by "induction," and so settling the matter. If this vague qualitative use of induction were got rid of, then as a name for a physical magnitude it would be unobjectionable. As it is, it is a question whether the physical magnitude should not have a name for itself alone.

"Resistivity" for specific resistance, and "conductance" for what is sometimes called the conductibility of a wire, *i.e.*, not its conductivity (specific conductance), but the reciprocal of its resistance, are, I think, as I have remarked before, quite practical names.

The further consideration of nomenclature must be postponed.—Yours, &c., OLIVER HEAVISIDE.

RESISTANCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician* of January 15th somebody wishes to be acquainted with the difference in resistance and conduction between a solid bar and a hollow cylinder of the same length and diameter.

On the one hand, the statement that conductivity is in the direct and resistance in the inverse ration of the area is proved fully; but, on the other hand, the assumption that electricity *flows over a surface* has never been proved and is altogether wrong. In the state of electrical equilibrium, where no motion takes place, electricity rests on the surface, indeed; but being in motion it must be supposed to be flowing through every part of the body.—Yours, &c., E. WENK.

116, Mildmay-road, N., 23rd January, 1886.

THE DYNAMO AS A GENERATOR AND A MOTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have to thank Mr. Walker for his kind remarks on my paper on "The Dynamo as a Generator and a Motor." With reference to Mr. Walker's criticism of some points in the paper, it is not necessary that I should do more than point out that he has apparently misunderstood those portions of my brief paper in which he considers that "from a controversial point of view" I have been unfortunate. He will see, if he looks over the paper again, that he is not correct in stating that I intimate that experiments point to a certain result, and then prove the contrary. It will, I am sure, be sufficient if I point out to him that he has confused a compound and a shunt dynamo. I do not mention the former in my paper.

With regard to the question of the efficiency of electric motors, I wish to point out that the tabulated figures given in the paper are not to be taken as indicating a low efficiency. An unascertained loss in transmission was *not included* in the horse-power readings, and should therefore be added to them. By a clerical error this unascertained loss is stated to be *included* in the horse-power column.

As a matter of fact, other experiments show that the commercial efficiency of the Victoria motors (or the ratio of the power delivered in a useful form at the pulley to that absorbed at the terminals) is over 80 per cent.

I am glad to be able to say that, since writing the paper, I have seen reason to considerably modify the view therein expressed as to the amount of the effect produced by the difference of the character of the induction of eddy currents in generators and motors. The difference will probably not be found of such importance as to furnish a very strong argument against the use of iron in the armatures of the latter.

I have read Mr. Brand's letter with interest, and am pleased to see that his experience accords so completely with the principles and views indicated in the paper.—Yours, &c.,

W. M. MORDEY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Some months ago in the course of a short conversation with Mr. Mordey I stated it as my belief that a practical computation of the loss by eddy currents and friction in a dynamo when run at a given speed could be made by running the dynamo as a motor with no load, the E.M.F. at the terminals being varied until the required speed was obtained.

Thus, $CE =$ the total energy delivered to the motor, where E is the E.M.F. at terminals and C the current flowing through the motor.

$CE - \{c^2r + c_2^2r_2\} =$ energy absorbed by friction and eddy currents, where $c^2r =$ energy absorbed by field-magnets, and $c_2^2r_2 =$ energy absorbed by armature, due to the inherent resistance of the wires, my argument being that whether the dynamo was used as a motor or as a generator, the loss from eddy currents and friction (neglecting the increase of the latter caused by the band when used as a generator) must be practically the same, especially as the brushes did not require moving.

Since a considerable time before the above-mentioned conversation I have subjected to this test the dynamos manufactured by the company with which I am connected, always remembering, however, that my theory was as yet unproved by experiment.

Mr. Mordey withheld a decided opinion, but thought that the conditions existing when the dynamo was run as a

Digitized by Google

generator would be very different to those which exist when used as a generator. It was, therefore, with particular interest that I read the reprint of Mr. Mordey's paper in your issue of the 15th inst.

I should now like, with your permission, to offer a few remarks on the subject in question—with some reference to Mr. Mordey's paper—the purport of which is sufficiently indicated by the heading of this letter.

Mr. Mordey's statements with reference to magnetic distortion seem to me to be rather confused, but I pass them over as unimportant. With reference to the speed of a motor when supplied with constant E.M.F. at terminals and varying load, Mr. Walker has shown with sufficient clearness that there can be no increase of current in the armature without decrease of back E.M.F., which, we may assume, means decrease of speed, as the total effect of self-induction, in the case of motors, tends to produce increase of field and consequent decrease of speed, as we shall see later on.

I would point out that the theoretical conditions under which a dynamo used as a motor *would* have a constant speed with a constant E.M.F. and varying load, are precisely those under which it would yield a constant E.M.F. with varying current when used as a generator—*i.e.*, when the armature resistance and self-induction are both *nil.*

At the end of his paper Mr. Mordey assigns a reason why dynamos should be less efficient as motors than as generators; but I think if he had investigated his theory a little more carefully he would have seen that if there is any difference in the eddy currents in the two cases it must be very trifling. What increase there is when the dynamo is used as a motor must be due to the lead of the brushes, as I will now endeavour to show.

With a dynamo having an infinite number of sections on the commutator (or the brushes sliding on the conductor), except at the point of commutation the current in the armature would be perfectly constant and stationary relatively to the iron core, and consequently its action would be *nil.* Or, to be more exact, we may say that as the induction due to the increase and decrease of the eddy currents in the core (as the iron approaches and recedes from the pole pieces) upon the steady current in the armature is inverted during half the process, the total result is *nil.* The effects of the rise and fall of the current due to a commutator with a practical number of sections are also equal and opposite. It appears, then, that the only part of the armature where the current in its coils can affect the E.M F. which produces the eddy currents (*without affecting similarly* the E.M.F. in the coils themselves, which it does by weakening or strengthening the general field) is the part surrounding the line of commutation, where there are what have been called "consequent poles," due to the change of direction of the current in the coils. These consequent poles will be respectively nearer the field-magnet pole on one side of them than on the other by the amount of double the lead of the brushes. In the case of the generator they will be nearer the pole of the same name as themselves, and will consequently be *lessened* in intensity by induction. In the case of a motor they will be nearer the pole of opposite name to themselves, and will consequently be *increased* in intensity by induction. If there were no lead, the consequent poles would be placed centrally between the field-magnets in each case; and the inductive effect the same, whether as a motor or generator.

But these consequent poles have a far more important effect than producing eddy currents in the iron, in a practical dynamo. They are the chief cause of the current in the short-circuited coil; and there, as I take it, lies one of the main causes of the inefficiency and excessive sparking of early dynamos when used as motors. The loss from this cause will obviously be at a minimum with the greatest possible number of sections in the commutator, and the smallest possible magnetising effect of the armature coils; and the *difference* between the loss when used as motors and the loss when used as generators will also be least when the magnetising effect of the armature coils and consequent lead is at a minimum.

The following tables, produced from Mr. Mordey's figures, show conclusively that the effect of the armature current on the eddy currents is practically *nil.* Column 4 represents the energy absorbed by the motor, and if Column 6 is subtracted from it the remainder represents friction (air churning) and eddy current.

1. Speed.	2. Energy delivered to motor h.-p. = $\left(\frac{CE}{746}\right)$	3. Useful h.-p.	4. Difference h.-p.	5. Efficiency.	6. Loss due to inherent res. of armature coils h.-p. = $\left(\frac{c^2 r}{746}\right)$.
975	6·8	1·8	5	26·5%	·053
965	12·4	6·6	5·8	53· %	·179
948	18·3	12·9	5·4	70·5%	·38
945	24·7	16·3	8·4	66· %	·69
680	3·9	1·	2·9	25·5%	·034
677	8·25	4·8	3·45	58· %	·153
675	13·7	9·14	4·56	66·8%	·42
660	16·5	11·7	3·8	71· %	·61

From these tables it would appear that the loss from eddy currents is actually less with a heavy current in the armature coils instead of being greater, as Mr. Mordey's theory would necessitate if it were true. But this is very likely due to considerable inaccuracies in the experiments and readings, which evidently exist, and which it is not easy to avoid.

If Mr. Mordey would favour us with the results of further experiments, he would, no doubt, confer a great boon on your readers, and I sincerely hope, with Mr. Walker, that he will be kind enough to do so.

In the case of the generator, the magnets are having work done on them by the armature, and the inductive result is to *strengthen* the magnetisation of both, but the effect of the armature current is to *decrease* that magnetisation.

In the case of the motor, the armature is having work done on it by the magnets, and the inductive result is to *weaken* the magnetisation of both, but the effect of the armature current is to *increase* that magnetisation. The relative strength of field of the dynamo when run as a generator and as a motor will therefore depend upon which of these two effects is the more powerful.

The first effect remains practically constant in each case. The second effect varies with the strength of current in the armature, and tends to produce a decrease of E.M.F. when the dynamo is run at a given speed as a generator, and a decrease of speed with a given opposing E.M.F. when run as a motor.

Early dynamos, as everyone knows, had far greater length of conductor on their armatures than those now constructed, and the magnetising effect of the armature (tending to increase the strength of field when run as motors) was very great. We know that when used as generators the total E.M.F. fell off considerably, on account of the reduction of the strength of field, or, as it is called, self-induction. So we may assume that when these machines were run as motors, the field strength was increased by the inverse action. Now, the effect of the increased strength of field is to produce the requisite opposing E.M.F. (which determines the limit of speed) at a slower speed, from which we should conclude that a motor will have a back E.M.F. of a given value, at a speed lower than the speed at which it would produce that E.M.F. as a generator.

From these considerations it appears that the following conclusions can be drawn:—

1. That it may be possible to construct dynamos which shall have practically the same efficiency *whether used as a generator or as a motor.*

2. A dynamo will have a given E.M.F. (opposing in the case of a motor) at a lower speed as a motor than as a generator, and the *difference* will be greater or less as the variation of strength of field from self-induction is greater or less.

3. *At the same speed* a dynamo will have a larger output when used as a motor than when used as a generator, and will require a greater E.M.F. to drive it than it would produce as a generator.

4. The loss of energy from eddy currents in a dynamo, whether used as a motor or as a generator, will be the same when the E.M.F. generated (opposing in the case of the motor) is the same.—Yours, &c.,, W. B. Sayers.

THE WORKING OF THE PATENT ACTS.

Writing on the subject of the new Patent Law just before it came into operation on the 1st January, 1884, we predicted that its working would demand and receive very close watching, which, in the course of a few years, would result in an inquiry and a remodelling of the Act. Our prophecy, in at least one particular, has come true rather sooner than we expected. After an existence of barely two years, the organisation and duties of the Patent Office, under the Patents, Designs, and Trade Marks Act of 1883, are to be overhauled by a Committee of the Board of Trade, and the investigation is now proceeding. We are not informed as to the exact defects which have called forth this step; but we may be sure that it is the outcome of complaints against either the provisions of the Act or the way it has been administered. In our article of December, 1883, we pointed out that in both respects the measure was seriously defective, its stipulations being delusive as affecting the inventive novice, and its working being liable to abuses that would press heavily on the experienced patentee. We have reason to believe that the warnings, which passed unheeded at the time, have been only too speedily realised, and that the present inquiry is the result of complaints which have grown too pressing to be disregarded. It is greatly to be hoped that the political incident of Tuesday night may not cause this Commission to be prematurely broken up.

Not the least of the evils introduced by the new Act was the multiplication of abortive patents, and the consequent expenditure of money by poor inventors, whose fees only serve to pay the salaries of the Patent Office examiners. The number of victims was less in the second year than in the first, but it is still extremely large. Out of 17,000 applications for patents made in 1884 no fewer than 7,000 became void through not being proceeded with, a fact which is painfully significant when we remember that the fee for securing the invention for the next three years is only £3. About forty per cent, therefore, of the inventions which the Act was framed to encourage prove to be not worth protecting for four years at the total cost of £4; and the fact remains that of substantial novelties which deserve and secure the privilege of protection there has been no increase at all proportionate to the decrease in the amount of preliminary and secondary fees. This is just what was to be expected. A patent to be worth having is worth as heavy a fee as is ever likely to be put upon it; and for the hypothetical chance of securing a sound invention from some person too poor to raise more than a sovereign at starting, we have tempted thousands of such men to spend their sovereigns for no advantage at all. Whatever may be said against high fees, they had certainly the effect of sobering the imagination and suggesting the expediency of caution.

Low fees, however, will probably be maintained, like many other questionable things that happen to savour of popularity. There would be less to say against them if they afforded any efficient guarantee; but, as was pointed out at the time, the preliminary examination for which the inventor pays his money insures him no sort of legal protection. The charge is not enough to cover a searching technical examination, and it might almost as well be dispensed with. In the later stages of patents that are proceeded with, amendments of specifications and the claims of opponents are adjudicated upon by the officials, as set forth in the Act; but this, too, is illusory, and, according to *The Times*, has created dissatisfaction on account of the incompetence of the examiners and the non-effective character of their decisions, whatever they may be. The Patent Office administrators have power to alter and amend; but not necessarily for the benefit of the patentee, whose claims may be upset in a court of law, notwithstanding, and perhaps because of, the very alterations made at the instance of the Patent Office. Either the decisions of the Patent Law officers ought to be final, or they ought not to be attempted at all.

One other inevitable consequence of the cheap patent has been a very large increase in the number of badly drawn up specifications. Litigation, which has always been the bane of popular Patent Laws, will, it is apprehended, be encouraged by the change in this country, as it has been in America. It may be too much to expect of the committee any drastic recommendation such as, if adopted, would give absolute security to a patentee when once his claims have been investigated and admitted. Nevertheless, our opinion remains unaltered that where patent laws exist ostensibly for the encouragement of invention, and not for purposes of revenue, it is the duty of the State to grant no privileges for a money consideration unless the grantor is satisfied they are for the public good, and will

Digitized by Google

undertake to defend them against all comers. One thing at least we may demand of the Committee, that they will put an end to the issue of patents to foreign applicants who obtain them merely to prevent English industry working the inventions for its own benefit. A correspondent of *The Times* assures us that the foreign patentee can be compelled to grant licenses for working his invention here. But the process of law is cumbersome, and attended with some risk. All foreign patents taken out under the English laws should be represented by an English agent, who, for the purposes of the Act, ought to be treated as the principal. As matters stand at present, an alien patentee can reap all the advantages to which a native-born subject would be entitled, without conferring on the country any of those industrial benefits which patent laws are designed to promote.

MOTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As an early user of motors, dating back so far as 1874, and ever since, a few words on this subject may be acceptable, seeing how much space is being devoted to this topic in your journal at this moment. The conclusions to which I have come are the following:—

The essence of a good dynamo is the essence of a good motor. Each can be used in turn as generator and motor with efficiency, and if this is not the case the machine is to be condemned. My experiments run over at least twenty machines, and although the tests on this head have been rough, yet they are conclusive. I am able to test the capacities of dynamos to a nicety, but not so with motors, so my practice is to "run them to ground"—that is, keep putting work on till the current reaches the carrying power of the wire. The results are surprising. Some motors will do double the work of others, although made for generators of equal power, and in some instances by the same maker. But in all cases the best motor made the best generator.

The manufacturers' tests are valueless for the workshop, and this is what so many will not recognise. No doubt a continual strain on the brake gives a result for the laboratory, but in a workshop matters are very different, one machine after another is put on or taken off, and the motor is greatly jerked and strained. Some motors "tear away" one moment and are nearly "pulled up" the next. The commutator suffers heavily in consequence, as well as the motor itself and the generator. I believe had it not been for this motors would have crept into all manufactories.

To avoid these difficulties manufacturers have given great speeds to their motors as compared with their dynamos, and it is mainly in this respect that motors have till recently differed from dynamos, *i.e.* the armatures were wound to have lower resistance and more carrying power. By this device the great variations in speed were in a way mastered, when work was thrown on and off; but these motors are difficult to start properly, even with resistances, and they are not very satisfactory in other respects. Such principles are an attempt to make the motor do what the equivalent size in dynamos could do, and would be condemned if such speeds were necessary.

For myself, a successful motor is of immense importance, for all the work here is done by means of them.

Till recently none have been satisfactory on all points, and inconvenience was caused every few days by some new adjustment being required to one motor or another. I have lately added two Elwell-Parker motors, which are built on scientific principles, and nothing really novel about them; but the effect is marvellous, no running away, no sparking, start as easily as possible, they do the same work as before with half the current and far more steadily, they do not shake the house at points 50 yards from the motor—in fact, there is no vibration six inches off, so I am well satisfied. The chief points about each motor are these:—Very well constructed electrically, the centre of gravity is very low, a broad base to rest on, speed moderate (same or rather less than for corresponding size dynamo), the armature perfectly balanced. This latter is what gives more trouble than can be supposed if absent. Vibration is produced, which is conducted to shafting and machines, till everything in a workshop gets out of truth. All my pulleys are ruined through badly balanced motors, and nearly every one has been replaced. The want of balance is even reflected to the generator, because the current becomes vibratory in character "in time" to the motor.

I will not name the makers of these motors, but may say that they stand high in public estimation.

We have eight to ten motors running here, and depend upon them entirely, so that any perfect machine is welcomed. The Elwell-Parker motors referred to are 1 and 4 horse-power nominal, but give far more power; in fact, the 4 horse-power at half the current intended for maximum does more work than the motor displaced did at near maximum, *i.e.*, current actually used in the two cases was at 20 to 45 amperes at 100 volts in each case.

There has been a tendency in manufactories to use large motors, and to distribute by means of shafting. This is right enough for a steam engine, but for electromotors it is a mistake. It is fair to assume that from the steam engine to the latter 50 per cent. of the power is lost for electrical means of distribution. This seems bad, but no one considers the loss of power by the use of heavy shafting. I think it will be found 30 per cent. of loss is below the mark, for in factories shafting is not always so well attended to as it should be, and alignment right at first soon alters and is "out of mind."

Now, with a steam engine, it must always run the whole of the main shafting; but if a small motor is placed to every machine throughout the factory, only the machine itself need run, or with its countershaft if required, and at such moments only when this machine is in use and at any desired variation of speed, if arranged for this. It is far easier to switch a current on and off than to shift a belt, and the factory roof may be lighter in construction by the absence of countershafting and shafting, and this process is clearly much more economical.

I have conducted experiments of a ludicrous kind to show the economy, viz., a gas engine running a dynamo in the same shop as the machines with small motors, and this showed a saving in gas over running the same machines with the shafting which existed direct from the gas engine.

This was a rough test, but a practical one, for the shafting was of the most modern kind.

The only difficulty to contend with was to find a satisfactory motor which would run smoothly, not spark, and be efficient besides. This appears now to have been found. I dare say that some readers may think that I have the firm of Elwell-Parker on the brain, after my letter published in your sister journal last week; but it is not the case. The fact is that most of the leading and old established firms have plenty of work in hand, and at all times view new departures with suspicion and dislike, because of the expense of altering standards, tools, and templates; whereas a new company starts with all the experience of the old ones, and, not being tied down by precedent, starts fair to meet new exigencies, if the managers are clever people. And it is with such advantages that Messrs. Elwell-Parker have started, and they will no doubt "wake up" the old firms to "move on" likewise.—Yours, &c.,

DAVID SALOMONS.

Broomhill, Tunbridge Wells, Jan. 23, 1886.

THE ROSENTHAL GALVANOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of January 22nd you speak of this instrument as an "addition" to the laboratory.

It can hardly have any claim to novelty, as galvanometers, with the mirrors outside the coils, and a long suspension, must have been in use for ten years at least, and I have made several myself during the past three years.

Digitized by Google

This method of construction has several advantages over the old-fashioned "Thomson," and when made astatic, with coils round both needles, is wonderfully sensitive; for example: With an astatic galvanometer, resistance 3·2 ohms, mirror 40 centimetres from scale; ·0000001 ampere gave a deflection of from 10 to 20 millimetres, and that with a quick return to zero.

I have not yet adopted silver wire in lieu of copper for the coils. Really, is it worth while to multiply the cost of wire fifty or sixty times for the sake of a possible gain in conductivity of 1 or 2 per cent.? One cannot help admiring the enthusiasm of Herr Rosenthal.—Yours, &c.,

SYDNEY EVERSHED.

Kenley, Surrey, January 26th, 1886.

THE TELEPHONE IN LONDON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been watching for some time to see if any of the subscribers to the United Telephone Company would ventilate their grievances in your paper. You have championed their cause on many occasions, and during the last few weeks have given the company a sharp reminder of the dangers of overhead wires. It is not, however, on this subject that I wish to address you, but on the matter of the general arrangements of the Telephone Company.

It seems to me that the subscribers to the United Telephone Company are the most easily pleased people on the earth. It is true that we have got so accustomed to being told that the number we require is "out of order," that we take little notice of that, but I contend the system is bad that regularly allows such things to happen. It is not once in a while only that we fail to get the subscribers we want, but I have been told in one day that five or six numbers, each situated in different parts of London, were out of order. This, however, is not the worst form of vexation that the subscribers have to put up with. We ring for a number. The answer comes in due course, "Out of order." We then spend a shilling or so in telegrams or employ a messenger, and when he is well started we find that our friends have managed to ring *us* up, and, to our surprise, inform us that "there is nothing wrong" with their instrument. The fact is the *employés* of the Telephone Company are getting as heedless of the subscribers' interests as the directors appear to be, and if there is any trouble whatever in getting a number, the exchange informs us it is "out of order."

What I have complained of here is repeatedly taking place, and I am sure many of the subscribers could confirm my assertions. I consider we spend two or three times as much on telegrams as we should do if the Telephone Company were efficiently managed. I have often asked firms with whom we do business to become subscribers, but they almost invariably answer that it would only be adding £20 a year to their expenses without diminishing their cost for telegrams. In this they are to a great extent right.

I account for the progress the telephone company has made in getting subscribers in London by the fact that the telephone is an invaluable invention, and recommends itself for use, but I deny that it has been of such service in London up to the present time as it might have been if properly managed.

For myself, I should be inclined to forgive the overhead wire system if only we could get a fair amount of attention, but if this is to blame for the many failures that occur, the sooner it is altered the better. If only a few of the many subscribers who are continually grumbling at the inattention they receive would take the trouble to publish their grievances, it is probable the Directors of the Company would go into the matter more carefully, and try to remedy some of the faults complained of.

I consider something ought to be done in this matter, and unless the United Telephone Company bestirs itself very soon many of the subscribers to their present system will either leave them altogether, or be ready to join any rival company that may be started. Trusting you will find space for this letter.—Yours, &c.,

London, January 27, 1886. SUBSCRIBER.

A CORRECTION.

Mr. H. Kingsford sends the following correction in his Paper, read before the Society of Telegraph-Engineers:—

$$\frac{\dfrac{a}{r+\dfrac{r''+R}{2}}}{2} = \frac{a}{c} = \text{current through fault.}$$

$$\frac{\dfrac{a}{r+\dfrac{r''+R}{2}}}{2} = \frac{a}{d} = \text{current through } x.$$

R_1 will equal $e - c$.

A NEW SOLUTION FOR ELECTRO-DEPOSITION OF METALS.*

BY G. GORE, LL.D., F.R.S.

The liquid employed was an aqueous solution of asparagine. It was not quite saturated, and consisted of about ·88 gramme of crystals of the substance, dissolved in 18·cc. of distilled water. The solution was faintly acid to test-paper, and was used at a temperature of about 70°C. Portions of this liquid were more or less saturated with different metallic oxides, and the resulting solutions electrolysed by currents from one to six voltaic couples, consisting of zinc and platinum in dilute sulphuric acid. The electrodes had usually one square centimetre of surface on each side.

Experiment 1.—·23 gramme of hydrated oxide of cadmium was mixed with about 20·cc. of the liquid; it did not all dissolve, and the solution was feebly alkaline. The mixture was electrolysed with an anode of cadmium and a cathode of copper. Adherent, white, reguline deposits of cadmium were easily obtained; no gas was set free at either electrode, and the anode remained clean and bright.

Experiment 2.—·28 gramme of zinc oxide was added to about 23·cc. of the liquid; the latter became alkaline. With a zinc anode and copper cathode, and a current from six cells, a moderately good deposit of metal was produced. No gas was evolved.

Experiment 3.—By using calcined magnesia in place of oxide of zinc, a current from six cells, and a magnesium anode, a film only was deposited upon the copper cathode, and that film evolved gas distinctly when wetted with dilute sulphuric acid. The amount of deposit was not increased by using a larger anode, a smaller cathode, and a more concentrated solution. Much gas was then evolved at each electrode. The mixture was alkaline to test paper.

Experiment 4.—·9 gramme of cupric oxide was partly dissolved to a blue liquid in 23·cc. of the solvent. With a copper anode and platinum cathode, a small amount of reguline metal was deposited by a current from six cells. Addition of a little ammonia to the solution decreased considerably the conduction resistance, but caused evolution of gas at the cathode during passage of the current, and the deposited metal to be soft and of a dark colour.

Experiment 5.—·1 gramme of dark red mercurous oxide was mixed with 21·cc. of the liquid. With electrodes of sheet platinum, a small amount only of mercury was deposited by the current from six cells. No gas was evolved. With yellow mercurous oxide the results were similar.

Experiment 6.—·33 gramme of oxide of silver was added to about 20·cc. of the asparagine liquid; the latter became

* Read before the Birmingham Philosophical Society, Jan. 21st, 1886.

Digitized by Google

feebly alkaline. With an anode of silver and a cathode of platinum, and a current from one, two, or four cells, good deposits of white reguline silver were obtained. No gas was set free.

Cyanide of silver was insoluble in a hot solution of asparagine.

EXPERIMENTS ON MECHANICAL MOTORS FOR TRAMWAYS.*

BY CAPTAIN DOUGLAS GALTON, D.C.L., C.B., F.R.S.

The following is a portion of Captain Douglas Galton's paper—that portion, in fact, dealing more especially with electrical motors :—

In the electric tramcar the haulage was effected by means of accumulators. The car was of the ordinary type with two platforms. It was said to have been running as an ordinary tramcar since 1876. It had been altered in 1884 by raising the body about six inches, so as to lift it clear of the wheels, in order to allow the space under the seats to be available for receiving the accumulators, which consisted of Faure batteries of a modified construction. The accumulators employed were of an improved kind, devised by M. Julien, the under manager of the Compagnie l'Electrique, which undertook the work. The principal modification consists in the substitution, for the lead core of the plates, of one composed of a new unalterable metal. By this change the resistance is considerably diminished, the electromotive force rises to 2·40 volts, the return is greater, the output more constant, and the weight is considerably reduced. The plates being no longer subject to deformation, have the prospect of lasting indefinitely. The accumulators used were constructed in August, 1884.

The car, as altered, had been running as an electric tramcar on the Brussels tramways since October, 1884, till it was transferred to the experimental tramway at Antwerp. The accumulators had been in use upon the car during the whole of this period, and they were in good order at the end of the experiments, that is to say, when the Exhibition closed at the end of October, 1885. The accumulator had forty elements, divided into four series, each series communicating, by means of wires fixed to the floor of the car, with commutators which connected them with the dynamo used as a motor. There were two sets of these batteries or accumulators, one of which was being charged in the shed whilst the other was in use. The exchange required ten minutes, including the time for the car to go off the tramway into the shed and return to the tramway. This exchange took place after every seven journeys. Therefore, the two batteries would have sufficed for working the car over a distance of about 42 miles during 16 hours.

It may be observed that the first service in the morning would be performed by means of the accumulators charged during the afternoon and evening of the previous day. Each element of a battery was composed of 19 plates, of which 9 were positive, 4 millimetres thick, and 10 negative, 3 millimetres thick. Each positive plate weighed 1·44lb., of which about 25 per cent. consisted of active material. Each negative plate weighed nearly 1lb., of which one-third consisted of active matter. The weight of the metallic part of the battery amounted, therefore, to 1,846lb.; and the whole battery, including the case and the liquid, amounted to 2,464lb., which contained 499lb. of active matter, or about 20·25 per cent. The four cases in which the battery was contained were so arranged as to divide the weight equally between the wheels. Two commutators enclosed in a box were placed on the platforms at the two ends of the carriage, so as to be available for moving in either direction. The accumulators were divided into four series of ten double elements, which, by means of the commutators, could be united under four combinations, viz:—

1st	4 series in quantity	1 in tension.
2nd.........	2 series in quantity	2 ,,
3rd	——	3 ,,
4th	——	4 ,,

Finally, a fifth movement united the four series in quantity, coupling them on each other, and putting the dynamo out of circuit, thus restoring equilibrium. When in a state of repose the handle was so arranged as to keep this latter switch turned on. The accumulators were arranged for charging in two series united in quantity, each containing twenty double elements. The charge was effected by a Gramme machine, worked by a portable engine. Each of these series received its charge during seven hours for the ordinary service of the car, and during nine hours for the accelerated service. The accumulators on the car actuated a Siemens dynamo, acting as a motor, such as is used for lighting, having a normal speed of 1,000 revolutions, fixed on the frame of the carriage. The motion was conveyed from the pulley on the dynamo by means of a belt passing round a shaft fixed on movable bearings to regulate its tension, and thence to the axles by means of a flat chain of phospor bronze. The chain was adopted as the means of moving the axle, on account of its simplicity and facility of repair by unskilled labour. The speed was fixed at four metres per second (which corresponds with a speed of nearly nine miles per hour), for 1,000 revolutions of the dynamo; and it was regulated by cutting a certain number of the accumulators out of circuit, instead of by the device of inserting resistances which cause a waste of energy. By breaking the circuit entirely the motive power ceased, and the vehicle might either be stopped by the brakes or allowed to run forward by gravity, if the road were sufficiently inclined. The reversal of the motor was effected by means of a lever which reversed the position of the brushes of the dynamo. The dynamo could be set in motion, and the carriage worked from either end, as desired. The handle to effect this was movable, and as there was only one handle and this one was in charge of the conductor, he used it at either end as required.

It should be mentioned that the car was lighted at night by two incandescent lamps, which absorbed 1·5 ampere each; and the brakes also were worked by the accumulators. The weight of the tramcar was 5,654lbs.; the weight of the accumulators was 2,460lbs.; the weight of machinery, including dynamo, 1,232lbs. The car contained room for fourteen persons inside and twenty outside. Under the conditions of the competition the car was required to draw a second car occasionally. The jury made special observations upon the work required to move the car between the 20th September and 15th October, 1885. Seals were attached to the accumulators. Moreover, from the 27th of September, after each charge, seals were placed on the belts from the steam engine to prevent any movement of the Gramme machine, so that there could be no charges put into the accumulators beyond those measured by the jury. The instruments used for measuring were Ayrton's ampere meter and Deprez's volt meter, which had been tested in the Exhibition by the Commission for Experiments on Electrical Instruments, under the presidency of Prof. Rousseau. Besides this Siemens electro-dynamometer and Ayrton's voltmeter were used to check the results; but there was no practical difference discovered. During the period of charging the accumulators, the intensity of the current and the electromotive force was measured every quarter of an hour, and thence the energy stored up in the battery was deduced. It may be mentioned that the charge in the accumulators, when the experiments were commenced, was equal in amount to that at their termination.

An experiment was made on 21st October to ascertain, as a practical question, what was the work absorbed by the Gramme machine in charging the accumulators. The work transmitted from the steam engine was measured every quarter of an hour by a Siemens dynamometer, at the same time the intensity of the electromotive force given out by the machine, as well as the number of the revolutions it was making, was noted. It resulted that for a mean development of 4 mechanical horse-power, the dynamometer gave into the accumulators to be stored up 2·28 electrical horse-power, or 57 per cent. The intensity varied between 25·03 and 23·51 amperes during the whole time of charging. Of this amount stored up in the accumulators a further loss took place in working the motor; so that from 30 to 40 per cent. of the work originally given out by the steam engine must be taken as the utmost useful effect on the rail. It was estimated that to draw the carriage on the level ·714 horse-power was required, or if a second carriage was attached, ·848 horse-power would draw the two together. This would mean that, say, 2 horse-power on the fixed engine would be employed to create the electricity for producing the energy required to draw the carriage on the level. The electric tramcar was quite equal in speed to those driven by steam or compressed air, and was characterised by its noiselessness and by the care with which it was manipulated.

Assuming the car by itself cost the same as an ordinary tramcar, the extra cost relatively to other systems was stated as being, according to the following figures, viz.:—The Gramme machine cost £48, the motor £208, and the accumulators 2·25 francs per kilogramme (10d. per pound). To these must be added the cost of erection, and of switches for manipulating the current, as well as the proportion of the cost of a fixed engine to create the electricity.

* * * * * * *

The original programme of the conditions which were laid down in the invitation to competitors, as those upon which the adjudication of merit would be awarded, contained twenty heads, to each of which a certain value was to be attached; and, in addition to these special heads, there were also to be weighed the following general considerations, viz :—*a.* The defects or inconveniencies established in the course of the trials. *b.* The necessity or otherwise of turning the motor, or the carriage with motor, at the termini. *c.* Whether one or two men would be required for the management of the engine.

As regards these preliminary special points, the compressed air motor, as well as the Rowan engine, required to be turned for the return journey, whereas the other motors could run in either direction. In regard to this, the electric car was peculiarly manageable, as it moved in either direction, and the handle by which it was managed was always in front, close to the brake. The carriage was the only one which was entirely free from the necessity of attending to the fire during the progress of the journey, for even the compressed air engine had its small furnace and boiler for heating the air. Each of the motors under trial was managed by one man.

The several conditions of the programme may be conveniently classified in three groups, under the letters A, B, C. Under the letter A have been classed accessory considerations, such as those of safety and of police. These are of special importance in towns. But their relative importance varies somewhat with the habits of the people as well as with the requirements of the authorities; for instance, in one locality or country conditions are not objected to, which in another locality are considered entirely prohibitory. The conditions under this head are :—

1. Absence of steam. 2. Absence of smoke and cinders. 3. Absence, more or less complete, of noise. 4. Elegance of aspect. 5. The facility with which the motor can be separated from the carriage itself. 6. Capacity of the brake for acting upon the greatest possible number of wheels of the vehicle or vehicles. 7. The degree to which the outside covering of the motor conceals the machinery from the public, whilst allowing it to be visible and accessible in all parts to the engineer. 8. Facility of

Digitized by Google

communication between the engineer and the conductor of the train. In deciding upon the relative merits of the several motors, so far as the eight points included under this heading are concerned, it is clear that, except possibly as regards absence of noise, the electrical car surpassed all the others. The compressed air car followed, in its superiority in respect of the first three points, viz., absence of steam, absence of smoke, and absence of noise; but the Rowan was considered superior in respect of the other points included in this class. Under the letter B have been classed considerations of maintenance and construction. 9. Protection, more or less complete, of the machinery against the action of dust and mud. 10. Regularity and smoothness of motion. 11. Capacity for passing over curves of small radius. 12. The simplest and most rational construction. 13. Facility for inspecting and cleaning the interior of the boilers. 14. Dead weight of the train compared with the number of places. 15. Effective power of traction when the carriages are completely full. 16. Rapidity with which the motor can be taken out of the shed and made ready for running. 17. The longest daily service without stops other than those compatible with the requirements of the service. 18. Cost of maintenance per kilometre. (It was assumed, for the purposes of this sub-heading, that the motor or carriage which gave the best results under the conditions relating to paragraphs 9, 10, 12, and 13, would be least costly with repairs.)

As regards the first of these, viz., protection of the machinery against dirt, the machinery of the electrical car had no protection. It was not found in the experiments at Antwerp that inconvenience resulted from this; but it is a question whether in very dusty localities, and especially in a locality where there is metallic dust, the absence of protection might not entail serious difficulties, and even cause the destruction of parts of the machinery. In respect of the smoothness of motion and facility of passing curves, the cars did not present very material differences, except that the cars in which the motor formed part of the car had the preference. In the case of simplicity of construction, it is evident that the simplest and most rational construction is that of a car which depends on itself for its movement, which can move in either direction with equal facility, which can be applied to any existing tramway without expense for altering the road, and the use of which will not throw out of employment vehicles already used on the lines; the electric car fulfilled this condition best, as also the condition numbered 13, as it possessed no boiler.

In respect to No. 14, viz., the ratio of the dead-weight of the train to passengers, if we assume 154lb. as the average weight per passenger, the following is the result in respect of the three cars in which the power formed part of the car:—

$$\text{Electric car} \ldots\ldots \frac{9,350\text{lb.}}{154 \times 34} = 1 \cdot 78.$$

$$\text{Rowan} \ldots\ldots\ldots\ldots \frac{15,950\text{lb.}}{154 \times 45} = 2 \cdot 30.$$

$$\text{Compressed air} \ldots \frac{22,000\text{lb.}}{154 \times 56} = 2 \cdot 55.$$

The detached engines gave, of course, less favourable results under this head.

Under head No. 15 the tractive power of all the motors was sufficient during the trials, but the line was practically level, therefore this question could only be resolved theoretically, so far as these trials were concerned. As regards the rapidity with which the motors could be brought into use from standing empty in the shed, the electric car could receive its accumulators more rapidly than could the boiler for heating the exhaust of the compressed air car be brought into use. As regards the steam motors, the following were the results from the time of lighting the fires:—

The Rowan—

In 34 minutes .... 3 atmospheres.
36 ,, ... 4 ,,
(At this pressure the vehicle could move.)
40 ,, ... 8 ,,

The Wilkinson—

In 35 minutes .... 2 atmospheres.
40 ,, ... 4 ,,
44 ,, ... 6 ,,
47 ,, ... 8 ,,

The Krauss machine required two hours to give six atmospheres, which was the lowest pressure at which it could be worked. The results under No. 17, viz., the fewest interruptions to the daily service, class the motors in the following order:—Krauss, electric, Rowan, Wilkinson, compressed air. The chief cause of injury to the compressed air motor arose from the carelessness of the drivers, who allowed the steam boiler to be burnt out. Unfortunately, these drivers were new to the work. Under the letter C are classed considerations of economy in the consumption of materials used for generating the power necessary for working.

19. Minimum consumption of fuel (either coke or coal), in proportion to the number of kilometres run, and to the number of places, assuming for the seats a width of at least sixteen inches for each person seated.

It must be borne in mind that the conditions of the competition required that a second car should be periodically drawn by the motor, and that the calculations which follow include the total number of miles run, the total amount of fuel, &c., consumed; and the total number of passengers which could be conveyed by each motor during the total time that the experiments were being carried on.

20. Minimum consumption of oil, of grease, tallow, &c. (the same conditions as in No. 19).

In addition to these considerations, it was thought useful to investigate the quantity of water consumed in the case of these engines which used steam. The experiments made on this point showed, as the consumption of water:—

	Gallons per mile.
Rowan	·75
Compressed air	1·06
Wilkinson	5·89
Krauss	6·52

Thus, owing to the large proportion of water returned from the condenser to the tanks, the Rowan actually used less water than the compressed air engine.

Table I. / **Table II.**

Description of motor.	Total number of train miles run.	Total consumption of fuel.	No. of lbs. per train mile.	No. of places indicated on the cars, per mile run.	Consumption of fuel.	No. of lbs. of fuel consumed per places indicated per mile run.
		lbs.			lbs.	
Electric	2,358·9	14,786·	6·16	80,203·5	14,786·	·18
Rowan	2,616·9	14,498·	5·42	148,399·6	14,498·	·09
Wilkinson	2,473·3	22,000·	8 82	119,085·1	22,000·	·18
Krauss	2,457·8	22,726·	9·10	108,983·9	22,726·	·20
Compressed air.	2,259·1	90,420·	39·48	128,189·3	90,420·	·69

Table III. / **Table IV.**

Description of motor.	No. of seats per mile run.	Consumption of fuel.	No. of lbs. of fuel consumed per seat per mile run.	Total number of miles run.	Total consumption of oil, tallow, &c.	Consumption of oil, tallow, &c., per train mile run.
		lbs.			lbs.	
Electric	61,591·2	14,786·	·23	2,358·9	99·0	·038
Rowan	135,928·8	14,498·	·10	2,616·9	106·7	·038
Wilkinson	93,965·6	22,000·	·23	2,473·3	255·4	·101
Krauss	86,039·9	22,726·	·25	2,457·8	188·5	·073
Compressed air.	132,732·7	90,420·	·66	2,259·1	585 2	·255

As regards the figures in these tables, it is to be observed that the consumption of fuel for the electric car is, to a certain extent, an estimate; because the engine which furnished the electricity to the motor also supplied electricity for electric lights, as well as for an experimental electric motor which was running on the lines of tramway, but was not brought into competition.

Conclusion.

The general conclusion to which these experiments bring us is that, undoubtedly, if it could certainly be relied upon, the electric car would be the preferable form of tramway motor in towns, because it is simply a self-contained ordinary tramcar, and in a town the service requires a number of separate cars, occupying as small a space each as is compatible with accommodating the passengers, and which follow each other at rapid intervals. But the practicability and the economy of a system of electric tramcars has yet to be proved; for the experiments at Antwerp, whilst they show the perfection of the electric car as a means of conveyance, have not yet finally determined all the questions which arise in the consideration of the subject. For instance, with regard to economy, the engine employed to generate the electricity was not in thoroughly good order, and from its being used to do other work than charging the accumulators of the tramcar, the consumption of fuel had to be to some extent estimated. In the next place, the durability of the accumulators is still to be ascertained; upon this much of the economy would depend. And in addition to this question, there is also that of the durability of parts of the machinery if exposed to dust and mud. After the electric car, there is no question but that, at the Antwerp Exhibition, the most taking of the tramway motors was the Rowan, which was very economical in fuel, quite free from the appearance of steam, and very convenient and manageable. The economy of the Rowan motor arises in a large degree from the extent of its condensing power, by means of which a considerable supply of warm water is constantly supplied for use in the boiler, and, consequently, the quantity of water which has to be carried is lessened, and the fuel is economised. Independently, however, of its convenience as a motor for tramways in towns, the Rowan machine has been adapted on the Continent to the conveyance of goods as well as passenger traffic on light branch railways, and fitted to pass over curves of 50ft. radius, and up gradients of 1:10. In England, with our depressed trade and agriculture, there is a great want in many parts of the country of cheap means of conveyance from the railway stations into the surrounding districts; such a means of conveyance might be afforded by light railways along or near the road-side, the cost of which would be comparatively small, provided that the expensive methods of construction, of signalling, and of working, which have been required for main lines, and which are perfectly unnecessary for such light railways, were dispensed with. It is certain that this question will acquire prominence as soon as a system of local government has been adopted, in which the wants of the several communities have full opportunity of asserting themselves, and in which each local authority shall have power to decide on those measures which are essential to the development of the resources of its own district, without interference from a centralised bureaucracy.

DISCUSSION.

Mr. PREECE, F.R.S., said he was a juryman at the Antwerp Exhibition, and though his official duties did not require him to inspect and report upon these tramcars, he took every possible opportunity of examining them, and, being an electrician, of travelling backwards and forwards on the electric car. He was delighted to find that the anticipations he formed, at an early period of the Exhibition, had been fully borne out by what Captain Galton had said. As an electrician, he had seen very great difficulties in carrying out a system of tramways worked by electricity; but, like all other difficulties, experience and study succeeded in removing them, and he had the greatest confidence in the future use of electricity for this purpose, whether applied directly or by the aid of accumulators. There was a great want of confidence in this latter system, the reason for which was not hard to discover, because they were thrust on the world long before either it was ready to receive them or they were properly developed. One of the first places in which the tide began to turn was in the Society of Arts. Some time back they had succeeded in lighting the hall by means of accumulators, and all present could see with what absolute steadiness the light was maintained. Captain Galton, at the end of the paper, said that undoubtedly, if it could be relied on, electricity would be the best motor for tramways; and that was the way in which everyone spoke of it. But there was no power on earth used for the service of man which could be so certainly relied on as electricity. He had no doubt, however, that we should yet live to see in London and the suburbs the Antwerp experiments repeated on a much larger scale.

Mr. A. RECKENZAUN said this was one of the most interesting and practical papers ever read on the subject of the mechanical propulsion of tramcars, but it would have been still more useful had the experiments been carried out on a line presenting more difficulties. It was very easy to travel on a level line, but very difficult to travel on an incline. For instance, if it required 2 horse-power on the level, it would take a 4 horse-power to go at the same speed up a gradient of 1 in 75, 6 horse-power for a gradient of 1 in 37, and 8 horse-power for 1 in 25, which was not very serious after all. Again, the sharpest curve on the line at Antwerp was only of a radius of one chain, and he was rather surprised it was not made sharper. He had recently been running a car in Berlin, where he had received much more encouragement than in London, and he believed a fair amount of business would be done there before any start was made in England at all. There, one curve was 11 metres radius, and there were several of 15 metres.

Mr. W. R. ROWAN could not agree with the two previous speakers. As far as he could gather the contest at Antwerp was really between two combined cars, the electric car and the steam car which he had designed. Having been there some eight or ten weeks, he could bear testimony to the great care and trouble taken by the jury over this question. There was no doubt that the most taking car was the electric motor, but the whole question from the first hinged on one word—economy; and the question would turn out to be, which was most economical, steam used directly in driving the car, or to produce electricity or compress air, which should then drive it? There were four main difficulties which he thought it would take electricians some time to get over. The first was the transmission of the power. The second difficulty was that of the accumulators; would they really last if knocked about daily in a tramcar? The trial at Antwerp gave very little information on that point, being short, straight, and level, so that they only had to be charged once a day. The third difficulty was the charging of the accumulators. In running up steep grades, and with grooved rails, which added greatly to the friction, he believed the accumulators would have to be charged five times a day, which would be a practical difficulty. Lastly, if all these difficulties could be overcome, he doubted if they could work as cheaply as with steam direct, seeing that only 25 to 40 per cent. of the power would be utilised.

Mr. B. DRAKE said there were one or two points in connection with the Electric Power Storage Company, which he represented, which he should like to mention. They not only used accumulators at their own works, but had supplied them for trial elsewhere, and in practical working it was found that, giving them the full charge, the efficiency in amperes was 75 per cent., and beyond that the loss in energy, expressed in watts, depended on the time at disposal to discharge them.

Mr. M. HOLROYD SMITH used electricity direct, and, therefore, there was no loss through the accumulators. The great question with regard to using electricity direct for street purposes was how to do it with safety to the public. By conveying the electricity underground, and having a means of communicating with it in the car, it was possible to utilise it without any danger either to the public or the traffic.

PHYSICAL SOCIETY.—January 23rd.

Prof. GUTHRIE, President, in the chair.

The following communications were read:—A note on the paper by Prof. W. Ramsay and Dr. S. Young, on "Some Thermodynamical Relations," by Prof. W. E. AYRTON and Prof. JOHN PERRY. The authors, after referring in the highest terms to the careful experimental work of Messrs. Ramsay and Young in their investigation upon "Some Thermodynamical Relations," the results of which were communicated to the society at its last meeting, show that the four laws stated in their paper are in reality only one, since if any one of them is assumed the remaining three may be deduced from it. Hence it is sufficient to examine only one, and of the four the third is in the form that can be most readily tested. This law, the statement of which is, that for all substances at any given pressure the product $t\frac{dp}{dt}$ is constant, p being the pressure and t the absolute temperature of saturated vapour at that pressure, is represented mathematically thus:—

$$t\frac{dp}{dt} = \phi(p) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$\phi(p)$ being a function of the pressure, independent of the substance. Writing this equation

$$\frac{dp}{\phi(p)} = \frac{dt}{t}$$

and integrating, we get

$$t = a\psi(p) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$\psi(p)$ being also a function of the pressure only, and a a constant depending only upon the substance employed. It is in this form that the authors have examined the third law. If true, it follows at once from (2) that the ratio of the temperatures of two saturated vapours to one another at any pressure is the same as the ratio at any other pressure. It is seen, however, either by reference to Regnault's numbers or Rankine's formula

$$\log p = d - \frac{\beta}{t} - \frac{\gamma}{t^2} - \ldots\ldots$$

an expression based upon his molecular theory, and which, as remarked by one of the authors at the last meeting, agrees with Regnault's results with remarkable closeness, that this ratio is far from constant. The authors are therefore compelled to conclude that the expressions given by Prof. Ramsay and Dr. Young must not be regarded as absolute laws.

A note on the paper, by Prof. J. W. Clarke, on the "Determination of the Heat Capacity of a Thermometer," by Mr. A. W. CLAYDEN. The author has applied a correction to an expression given by the late Prof. J. W. Clarke, for measuring the heat capacity of a thermometer, in a paper communicated to the Society at a previous meeting (April 25, 1885.) Prof. Clarke's expression was affected by the mercury not entirely filling the bulb and stem of the thermometer. The corrected expression obtained by the author is

$$V_1 = \frac{V(s - s_2)}{s_1 - \frac{s_2(1+\beta t)}{1+at}}$$

s, s_1 and s being the mean densities of the instrument, mercury, and glass respectively, β and a the coefficients of voluminal expansion of mercury and glass; V and V_1 the volumes of the instrument and of the mercury.

"Note on some Organic Substances of High Refractive Power," by Mr. H. G. MADAN. In the course of some correspondence respecting M. Bertrand's polarising prisms, the author was informed that the cement used was napthyl-phenyl-ketone dibromide. He has consequently prepared specimens of the ketone, and subjected them to optical examination. The ketone is a thick yellow oil, boiling at a temperature near the boiling point of mercury; it appears to be a very stable, neutral, and harmless substance like Canada balsam, but unfortunately it does not appear to be capable of hardening, and hence is not by itself adapted for a cement. Its refractive index for the D line is 1·666, higher than that of carbonic sulphide, while its dispersive power is approximately the same as that of that substance. The author has made the bromide of the ketone referred to above; but it seems liable to decompose with formation of hydro-bromic acid, which acts upon the spar. Mr. Madan also exhibited a specimen of metacinnamene, a highly refracting glass-like solid obtained by the action of light or heat upon cinnamene. This substance possesses a retractive index of 1·592 for the D line, and would make a valuable cement if it showed a firm adhesiveness for glass.

The PRESIDENT exhibited and described an instrument he had made in the course of an acoustical investigation upon which he had been engaged. It is a musical instrument similar in principle to the harmonicon. In the case of the harmonicon the rectangular plate is usually supported by strings passing through the nodes, but the author wished to make an instrument that could be "bowed." The nodes are not absolute positions of rest, the particles at them describing curves having cusps pointing outwards. The plan adopted was to solder two springs to the plate, which was of brass, the points of attachment being slightly outside the nodes, and the springs being such as to give the same fundamental note as the plate. The other ends of the springs were attached to the mouth of a resonator, whose fundamental note was also that of the plate. The plate, when struck or bowed, gave a tone very like that of a tuning fork, and, in a discussion that followed, Prof. S. P. THOMPSON suggested the possible use of these instruments as a substitute for a series of forks, the cost of a complete set of which often placed them beyond the reach of the student. Prof. McLEOD suggested that the springs should be tuned to the octave of the plate instead of to its fundamental, and that they should have a slightly different form.

THE PERSIAN GULF TELEGRAPH CABLE.

The following report to the Under Secretary of State for India, by Sir J. U. Bateman-Champain, R.E., K.C.M.G., giving details of the operation of laying the new cable from Bushire to Cape Jask, in the Persian Gulf, will be found interesting:—

Indo-European Government Telegraph Department,
Karachi, Dec. 1, 1885.

On the 29th of April I received instructions from the Right Honourable the Secretary of State to take the necessary steps for obtaining tenders for

Digitized by Google

the manufacture of a new cable to be laid between Jask and Bushire, and also to arrange in due time for its shipment and submersion. On the 18th of June the manufacture was commenced at Silvertown. The work went on smoothly and satisfactorily under the electrical supervision of Messrs. Clark, Forde, and Taylor, who undertook to maintain careful and constant testing at the factory. After arranging for the making of the cable, the next most important consideration was the engagement of ships in which to convey it to the Gulf and there safely deposit it at the bottom of the sea.

We calculated that the expedition would last 100 days from the time the ships left Silvertown till their return to that place. We required more than 3,000 tons gross tonnage, and it was essential that the ships should be fitted with cable tanks, paying-out machinery, testing rooms and appliances, a steam launch, and other apparatus. Our own cable hands and Lascars at Karachi would not be sufficiently numerous for the work, and therefore it was made a condition in the charter party that the vessels should carry and place at our disposal a certain number of experienced cable hands, to whom, as well as others of the ships' companies directly employed in the operations, a gratuity of half a month's pay should be granted by Government on the successful completion of the work.

Eventually the two cable ships, "Dacia" and "International," the property of the India Rubber and Gutta Percha Telegraph Works Company, were engaged for a lump sum of £17,500. Twenty-one days after the arrival in India were to be given for the completion of the work, after which demurrage, at the rates of £100 per diem for the "Dacia" and £75 for the "International," was to be paid by the Government. For the important duties of testing the cables on the outward voyage I sent for Mr. Harrison (an acting assistant superintendent in my department) from Karachi, and placed him in charge on board the "International." Mr. F. Maclean, a superintendent of the Indian Department, returning from furlough, volunteered to test the cable on the "Dacia." As regards the loading of the vessels, the best way in which to distribute the cable in the different tanks, and the condition of the cable machinery, &c., we took the professional opinion of Mr. F. C. Webb, an electrical engineer of great experience, who was in former years employed by the Government of India on the Persian Gulf cables, and his reports were of great use.

The cable was all on board by September 20; Messrs. Clarke, Forde, and Taylor's certificate was thoroughly satisfactory; and on September 19 I decided that the "Dacia," with Sir Henry Mance, myself, and others on board, carrying 339 miles (1,260 tons) cable, 350 tons coal, and 140 tons stores, should sail from Greenhithe for Karachi on October 6. The "International," with Mr. Harrison in charge, and 191 miles (735 tons) cable, 260 tons coal, and 90 tons stores on board, was to sail three days later, direct for Jask.

Complete information as to our plans and instructions as to local preparatory action had been previously supplied to Mr. Ffinch, and through him to Captain Bishop, commanding the departmental cable vessel, the "Patrick Stewart." The last-named ship was to join us either at Karachi or Jask. We reached Karachi on the morning of November 10, and, after taking on board Mr. Ffinch, several clerks, foremen, and cable hands, European and native, and a considerable amount of cable stores and paraphernalia, we sailed again on the evening of the 11th for Jask. We began rather badly, the "Dacia's" steam launch "carrying away" while being hoisted, and flinging a man overboard. Life buoys were thrown to him and he was promptly picked up, but we were compelled to leave the sunk launch, buoying the spot so that she could be recovered heareafter. On the morning of November 14 we anchored off Jask, and were pleased to find the "International" awaiting us, she having arrived direct from Aden the previous evening. The "Patrick Stewart" steamed in from the Gulf four or five hours after ourselves. Mr. Harrison reported that the cable under his charge was, like our own, in perfect order.

Next morning, the 15th, the actual work of laying the third Persian Gulf began. At this moment all communication with Europe by our line was suspended, owing to a break in the 1869 india rubber cable close to Jask. The "Patrick Stewart" promptly repaired this, and at the same time the "International" began landing our new Jask shore end. By means of balloon buoys, and thanks to the magnificently calm weather, the heavy end from ship to shore, half a mile or so long, was safely laid in the incredibly short space of thirteen minutes. At 12:30 we commenced paying out from the "International" towards Bushire at a speed of about four knots an hour. The "Patrick Stewart" led the way, and the "Dacia" followed us, taking frequent soundings for our information and guidance hereafter. The repair of the india rubber cable was very lucky, as we were now in direct telegraph communication, not only with Jask but also with our goal, Bushire, and were thus kept acquainted with the state of the weather ahead.

On the morning of the 17th we had laid the 191 miles of cable from the "International" and buoyed the end. We transferred ourselves, our staff, and stores to the "Dacia," and bade good-bye to the other vessel, which by 10:30 a.m. had finished all she had to do for us and was under way for Karachi. After splicing on to the buoyed end of the cable we started afresh for Bushire. On the 18th the sea was somewhat rough, but so smoothly and well did the machinery work that no anxiety whatever was experienced, and we were able to pay out at a rate of over six knots per hour. That night, it seems, the "Patrick Stewart" hardly made sufficient allowance for current, and led us a few miles further south than the course intended. This was somewhat unfortunate, as the soundings showed that we passed over a shoal which we meant to avoid. On this patch we laid the cable in fifteen fathoms depth instead of forty, and there is some cause for fearing that the irregularity of the bottom may in course of years tell on the cable and cause a break. It may be desirable to lift and relay this short length, at some future date, a work which the "Patrick Stewart" can perform with ease at any time.

Early on the 20th we had laid the whole line to within six miles of Reshire, the site of the Bushire telegraph offices. The main cable was cut and buoyed, and by 9 p.m. the shore end was laid and joined up in the cable office and the work was satisfactorily finished. I believe no smarter piece of cable laying has ever been done. Thanks to Sir Henry Mance's admirable foresight and powers of organisation, and thanks to the energy and devotion of our departmental officers and men engaged, more than 500 miles of cable (sanctioned only in the latter end of spring) have been laid in perfect order, and at an extraordinarily small cost, punctually by the date foretold. We are thankful to have been favoured by the weather, and, with the exception of the little accidents noted above (which did not interfere with the work), no difficulty, no unpleasantness—in short, no hitch, occurred from first to last.

We arrived at Karachi on November 29, and relinquished control of the "Dacia" on the 1st of December, having employed the ship for a little less than the 21 days allotted for our task.

I now beg to be allowed to repeat that to Sir Henry Mance is due the credit of what, I trust, will be admitted has been a thoroughly successful expedition, but I must say that the other gentlemen engaged performed their very important functions with the greatest zeal and assiduity. The staff was divided into two watches, neither being day or night more than four hours at a time off duty. The records and observations kept during the laying will be fully described in the engineer's report, which I think ought to be printed when we return to London. Messrs. Possman and Sealy had charge of the watches, and were untiring in their exertions. They were most ably assisted by Messrs. Harrison, Allen, Andrews, and Hopkins, of this department, while records of the soundings, of the position of the paying-out ships, and the amount of cable expended at any particular minute, with a variety of other useful details, were, under Messrs. Possman and Sealy's superintendence, kept with admirable precision and care by Mr. Twisaday, of my London office, and Mr. Bailey, an *employé* of the India Rubber and Gutta Percha Company. Four or five junior clerks were told off for day and night signalling by steam whistle, flags, or hand lamps to the "Patrick Stewart. Mr. Brown and the foremen and cable hands under his immediate charge likewise carried on their share of the work as well as possible. I must also express my warmest thanks to Mr. Pfinch, the Persian Gulf division, for the accuracy and completeness with which everything at Karachi and at the Gulf stations had been prepared for us beforehand. Mr. Ffinch accompanied the expedition, and co-operated with Sir Henry Mance and myself in the most cordial and energetic spirit.

Lastly, I desire to record my warm appreciation of the conduct of the officers and men in the employ of the India Rubber and Gutta Percha Company on both the ships "Dacia" and "International." Captain Tindall, of the latter vessel, and Captain Wilson Barker, of the former, helped us in every possible way, and nothing was omitted which could assist in making the voyage out agreeable and the cable laying successful. Both ships were, as is the custom with the company, under the absolute orders and control of Mr. Theophilus Smith, an electrical engineer of experience and ability, to whom, for his great kindness and constant attention, we all feel sincerely grateful. I can truly state that from the day we embarked at Greenhithe till we finally left the "Dacia" this day, there has been, thanks in a great measure to Mr. Smith's tact and consideration, no dispute or difference of opinion of any sort between the officers of the Government and those of the India Rubber and Gutta Percha Company.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The twenty-seventh half-yearly ordinary general meeting of this Company was held on Thursday, January 21st, 1886, under the presidency of John Pender, Esq.

The SECRETARY read the notice convening the meeting, and the minutes of the last general meeting and the report having been taken as read,

The CHAIRMAN said: Gentlemen, although the report which you have all no doubt had the pleasure of perusing is as full and complete as it is almost possible to make any report submitted to a body of shareholders, I am anxious, and so are my colleagues, at all times that the very fullest information which we possess should be given to the shareholders at these half-yearly meetings. I have, therefore, some detailed remarks to make which go more or less to confirm the report and to explain it more in detail. The revenue for the last six months, ending the 30th September, 1885, amounted to £331,420, against £309,569 in the corresponding period of last year, or an increase of £21,851. The return on our investment in the Eastern and South African Company shows a falling off for the half year of £1,950, the dividend having been at the rate of 7 per cent. instead of 8 per cent. On the other hand, our return from the Black Sea Company shows an increase of £771. I am pleased to observe that our Indian traffic, which has been stationary for some years, shows some signs of revival, but the main increase of traffic in the six months' accounts which we are now considering is owing to the military operations in Egypt and Burmah. Our Australian, China, and Tonquin

Digitized by Google

traffic was very good during the greater portion of last year, but I may say that since the middle of December there has been a considerable falling off. We may, however, hope that the reduction is only temporary, and that there will before long be a general expansion of business from which the Company will certainly benefit. The total working expenses amounted to £86,935, against, in the corresponding period of 1884, £84,907, being an increase of £1,928. The principal items, showing increases and decreases, are as follows:—General expenses in London, a decrease of £2,881; salaries and wages, office expenses, and stationery, and printing show increases. These items are directly affected by the increase of business, and the gradual growth of our system. Advertising, repairs, and renewals of furniture, and law charges show decreases. The working expenses at stations amount to £60,497, against £58,009, or an increase of £2,488. The details are as follow:—Salaries and wages, as compared with September, 1884, show an increase of £3,568, but as compared with the last half-year the increase is only £1,930. We have opened out new stations at Parliament-street, Westminster, and Perim in the Red Sea. There is also a full six months' working of Katacolo and Patras, against two months of the former and one month of the latter during the same period of 1884. There has also been an increase in the number of clerks at stations where the pressure of business is greatest. I may state that the total number of the staff at September, 1884, was 526, and at September, 1885, the number was 562, being an increase of 36. Promotions have also been made in certain cases where high proficiency and length of service have entitled them to the recognition of the Board. Repairs and renewals of furniture show an increase of £790. The principal expenditure under this head is at Gibraltar, the cause of which I fully explained at the last meeting. There are also included the first charges for fitting up the new stations to which I have just referred. Repairs to stations show an increase of £660. We have made considerable sanitary improvements at our Training School at Porthcurno, and repairs have been effected to our property at Carcavellos, Alexandria, and Aden. Provisions and rations allowance exhibit an increase of £248, mainly at Suakin and Perim. There is great difficulty and expense in obtaining good food for our young men at these places. A special allowance is, therefore, made to the staff at these stations. There is, on the other hand, a reduction in the following items. Travelling expenses decrease £1,355; rent, fuel, and light, £994; expenses of land lines £841, petty expenses £122.

With reference to the items shown separately in the revenue account, use of patents shows a decrease of £1,888. This important reduction is due to the expiration of Sir William Thomson's patents, to which I took occasion to refer at the last half-yearly meeting in very complimentary language as to the enormous benefit which those patents of Sir William Thomson have conferred on submarine telegraphy. I believe we could not possibly have brought submarine telegraphy up to the high position it occupies now as a great commercial power had we not had the advantage of Sir Wm. Thomson's patents. He has reaped a very fine harvest from them. The patents have now expired, and we are continuing to derive those advantages from them, and I hope they will rather increase than diminish. The next point is the depreciation of cable stores and London office furniture. Here there is an increase of £2,508. A larger stock of cable had to be depreciated this half year, and ample provision has also been made for the depreciation of London office furniture and fittings incidental to the changing of our head offices. Maintenance ships' reserve fund shows an increase of £2,000. The Directors, taking the view that the ships are tools for repairing our cables, have decided to again make a special provision to this fund. I may remind you that we were able to charge the cost of the "Volta," one of our ships, to this fund, and we hope that the revenue will continue sufficiently good to enable us to reserve about £5,000 each half-year, so that we can apply the total cost of our new ship, the "Mirror," in the same way. We shall then have added two ships to our fleet without having increased our capital account. That is what we are considering at the present time, and we give you our full confidence in telling you what we anticipate to do, though we have not definitely decided that that course will be pursued. However, our great object, as you know, is to keep down our capital, and as far as possible strengthen our system from revenue without unduly crippling our dividends. The staff endowment assurance is £1,661. This account remains about the same. The proportion of cable tanks at stations, £500. This item is the same as last time, and the same remarks apply as to the ships.

I may mention that, so anxious are your Board to make our system efficient and to be ready at all times on the shortest notice to make a repair, that we have established large tanks at our important stations in the Mediterranean and the Red Sea, where we can keep a certain stock of cable, and we have generally a ship somewhere in the neighbourhood of those tanks, so that instead of a vessel having to come to England for supplies, we are ready to ship them within a few hours near the point where the interruption has taken place. That is an enormous benefit to telegraphy and the shareholders, because the interruption of any one of our lines for any length of time, as you know, means a very large falling off in our revenue.

The expenses as to the negotiation of the Direct Spanish wires were £250. The Directors' remuneration is the same. The expenses attending repairs and renewals and laying cables amount to £45,288, against £31,189, or an increase of £14,099. It will be seen on reference to abstract "C" that full details of the work done by our ships are given. They have been constantly employed in the half-year, and in addition to the numerous important repairs effected, the "Volta" has laid a duplicate Chio-Syra cable, and completed the final sections of the Greek cables, which entitles us to a prolongation for ten years of the subsidy granted by the Hellenic Government. There is also included the charter, outfit, and the expenses of cancelling charter of the ship "Ardmellie." This vessel was chartered at a time when the relations between this country and Russia were very much strained, owing to the difficulties in Afghanistan. Had war broken out, it would have been absolutely indispensable to have our ships stationed at various points beyond Suez, in case the Canal should have been interrupted, and several of our ships would have consequently been rendered useless this side of Suez for repairs. Political affairs becoming settled, we cancelled the charter of the "Ardmellie," and decided to build a new ship, to be on hand for emergencies. For similar reasons it was decided to increase our cable tank accommodation, and this puts the Company in a very efficient position for the maintenance of our cables under any circumstances. We can, therefore, be useful to Her Majesty's Government on emergencies in the laying of cables expeditiously along our route. The shareholders will be aware that the Company has on several occasions been of special service to Her Majesty's Government, and to the commanders of our army and navy at Besika Bay, Constantinople, Alexandria, Port Said, and Suakin.

We have transferred the Sardinian cable reserves to the general fund, which now amounts to £429,178, our total reserves being £444,875. After charging all expenses, including income-tax, on our net revenue, providing for interest on debentures and debenture stock, and preference shares, we are enabled to pay a dividend, with bonus, at the rate of 6 per cent. per annum, and to carry forward £32,549, against £30,369 in the corresponding period of last year.

Now, gentlemen, I think I have given you an amount of detail which is not generally given in companies. But we have thought it desirable that, flourishing Company as we are, we should give you some opportunity of judging how we conduct the affairs entrusted to our charge; and while we manage them on a broad principle we also observe, as far as it is in our power to do so, the strictest possible economy.

There are some points referred to in the report which I am bound to allude to more particularly to-day. One of the first I have to draw your attention to is the Conference that was held at Berlin during the months of August and September last. I had the pleasure of being present with your Managing Director, Sir James Anderson, and several members of our staff. At that Conference we had a very important part to play, and the reason we had such an important part arises from the fact that these submarine companies represented at that meeting something like 100,000 miles of submerged cable, costing about £35,000,000 sterling. The whole of the submarine cables belonging to the Powers of Europe represented something like 7,300 miles, or about £1,500,000. I may say further that if you take the value of the submarine cables represented at the Conference by the different companies, it exceeds the cost of the whole of the land line system represented at that Conference. You can therefore see that the position we held was one of great importance, one that required considerable intelligence to defend; and it required a considerable amount of power and influence to impress upon the gentlemen attending that Conference how important it was for them to maintain the submarine system as far as it was in their power to do so. The submarine system benefits not only this country, for there is no country in Europe that it does not benefit to precisely the same extent, measured by the amount of commerce which they have with other nations scattered over the world. Consequently, while we have conferred this enormous boon upon the commerce of the world, and upon the countries engaged in that commerce, we have derived no special benefit from it. We are not even allowed to vote at these Conferences, and we must have a very good case or we could not maintain our position so well as we have done. At the last Conference the great object of Germany was to get something like a universal rate established for submarine telegraphy on the Continent. The German Minister of Telegraphs and Posts—a man of great power and intelligence—had been successful in establishing the universal postal system, which, I believe, has been of enormous benefit to the world at large. He thought it possible to introduce the system into telegraphy; but he found that telegraphy was a very different thing from the postal system. The consequence was that while he brought other Powers to reduce materially the rates for Continental messages, and in reducing those rates interfered considerably with our European tariff, still, after all, we found ourselves at the end of the Conference in this position. Reductions were made first to India, involving a sum of something like £27,000. The reductions which we shall be obliged to make in our European system amount to something like £13,000. Consequently, the gross amount that we may have to submit to in reductions is about £40,000. That is a large sum, gentlemen, in one sense, but it is not a large sum in another. I believe that now we see something of the dawn of better trade. We see it moving in more parts of the world than one, and there is no better evidence or a better barometer of trade than our telegraph system, and we believe that the reduced rates will contribute very largely to increased traffic, and through that increased traffic we look in a very short time to recoup ourselves for the loss which we sustain more immediately. Therefore, I do not look at that reduction in any light than that of casting your bread upon the waters, and that you will find the return after many days. Now, we had not a very great amount of encouragement in fighting our battle at Berlin. We fought it, I believe, manfully and intelligently. We had not the Press all in our favour, but the Press deliberately declared that their object was to get reduced rates, and they did not care how those rates were brought about, whether it killed us or not. Their object was to get reduced rates, and they did everything they possibly could to bring that about. I am glad to say that we were in too strong a position to be influenced by the remarks they made. But while I say that I must say one kind word for them. When war does take place abroad they are very generous and liberal to the public in providing an amount of telegraph matter which it would be impossible for other than the great newspaper power of England to pay for. Therefore, while we express a little regret at the want of sympathy of the Press on the one hand, we are bound to express our gratitude to them for the liberal support they give us when it becomes necessary for them to employ us. I may also say at the same time that I believe the Press finds in

Digitized by Google

telegraphy a source from which to supply at any time an amount of information which would probably cost them a great deal more to pay for if such information were obtained through different channels. Therefore we stand pretty well with the Press, and in an independent position. We shall always be happy to be of use to them if we can, because we know they are of use to us when it becomes necessary for them to be so. I have given you these particulars about that Conference, and another Conference will not occur again for five years, during which we have much to do, and I hope at the end of that period we shall occupy a better position, financially and commercially, than we did before the Conference which is just ended.
